This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world’s books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that’s often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book’s long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ **Make non-commercial use of the files** We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ **Refrain from automated querying** Do not send automated queries of any sort to Google’s system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ **Maintain attribution** The Google “watermark” you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ **Keep it legal** Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can’t offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book’s appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google’s mission is to organize the world’s information and to make it universally accessible and useful. Google Book Search helps readers discover the world’s books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at [http://books.google.com/](http://books.google.com/)

HABENARIA, a genus of plants belonging to the natural order Orchidaceae. The tribe has a ringed hooded perianth, a 3-lobed entire spurred lip. There are three species natives of Great Britain.

Habenaria viridiflora, the Frog Orchis, has a very short 2-lobed spur, linear flat 3-pointed lip, the middle point the shortest. The flower is green, and the lip of a brownish colour. It is the Peristylus Lindley, and the Himantoglossum of Reichenbach. In this it is in point.

H. bifida, the Lesser Butterfly Orchis, is distinguished by the lip being linear and entire, and the pollen masses parallel. The flowers are white. It is found in healthy places.

H. chlorocephala, the Great Butterfly Orchis, has the same general characters as the preceding species; but the flowers are larger and the plant is taller and stouter. The pollen masses ascend obliquely and converge upwards. It grows in moist woods and thickets.

(Babington, Manual of British Botany.)

HABINGTON, WILLIAM, was the son of Thomas Babington, a Roman Catholic gentleman of family and fortune in Worcestershire. His mother, the daughter of Lord Morley, has been supposed to have been the writer of the famous letter which revealed the Gunpowder Plot [Fawkes, Gun, P.C.]; and her husband (who had been long imprisoned as implicated in Babington's conspiracy) gave shelter to some of the accomplices of Fawkes, and was sentenced to die, but received a pardon through the intercession of his wife's brother, on condition of retiring to his manor of Hindlip. Their son had been born there upon the very day now marked as the date of the plot, the 5th of November, 1605. He was educated in the Jesuit college of St. Omer, and afterwards at Paris; and endeavours were used, but in vain, to induce him to enter the society. He returned to England, and lived in retirement with his father, who long survived him, and who directed and co-operated with him in historical and other studies. William Babington married Lucy, daughter of William Herbert, the first Lord Powis; and the whole of his subsequent life appears to have been spent in literary and rural quiet. It is said by Anthony Wood that he "did run with the times, and was not unknown to Oliver the Usurper," a charge which may either he untrue or involve nothing discreditable. He died at Hindlip on the 18th of November, 1664, when he had but just completed his fortieth year. His published writings were the following:—1, 'Castars,' a collection of poems, first printed together in 1635, and again more fully and correctly in 1640. They were included in Chatterton's English Poets in 1810, were reprinted separately in 1812, and are given wholly in Southey's 'Select Works of the British Poets.' The name at the head of them is the poetical one he gave to the lady whom he married. They are in three parts: the first containing sonnets and other small pieces, chiefly addressed to his mistress before marriage; the second part containing similar poems, chiefly addressed to her as his wife; and the pieces in the third being mainly religious and contemplative.

H. Sudbury, a celebrated German landscape painter, was born at Prenzlau in Prussia, in 1737. His father was a portrait painter and a native of Berlin, where Hackert spent some time with an uncle who was a decorative painter. He acquired his chief knowledge of painting, however, by copying good pictures; and he derived great benefit also from the acquaintance of Le Swuir, the director of the Berlin Academy, and of Sulzer. In 1765 he visited Paris, and in 1768 he went, with his brother Johann, to Italy. They spent some time in Rome sketching and painting the scenery about Albano and Tivoli; many of their works were purchased by Lord Exeter. Philipps's first works of importance however were the six large pictures of the Russian
naval victory of Tychæsme, and the burning of the Turkish fleet, by Count Orlov, in 1770, painted for the empress Catherine II. of Russia, and for which he was paid 2500 rubles, in 1771, or 1600 florins, at Venice, to Count Orlov, to whom the works were sent at Leghorn, was upon the whole highly gratified by their successful accomplishment, has given the painter the representation of the execution of a ship, in the picture of the burning of the fleet; and in order to give the artist a proper impression of such a catastrophe, he ordered, with a spirit worthy of an autocrat, one of the frigates of the fleet, and old vessel, to be blown up, in the presence of Hackert, in the roads of Leghorn, and he was well satisfied with the results of his experiment, for Hackert greatly improved the picture. These works, with six other similar subjects, he exhibited in the year 1772, at Venice, and the spirit of his productions, as also the name of the artist, is evident in the whole of his recent productions. As, for which supposition however we find no plausible ground, but he adds, 'unless you would rather have it from the French Hackney,' which is a word of similar meaning. Many emigrants to Hackney, and Hackney-carriage, in the 20th year in which the first-mentioned pictures were completed, Johann Hackert died at Bath, aged only twenty-nine; he came to England with some pictures which had been ordered by English travellers in Rome. In the meanwhile two other brothers, Wilhelm and Karl, joined Philipp in Rome, but William went shortly afterwards to St. Petersberg, and died there in 1780, aged only thirty-two, and Karl settled in Sitterted. Philipp accordingly in 1778 sent for his youngest brother Georg, who was an engraver at Berlin, and they lived together from that time until the death of Georg at Florence in 1795.

Hackert was highly patronised in Rome both by Italians and foreigners; Pius VI. was delighted with his works, and his reputation as a landscape painter was unrivalled by any of his contemporaries, though praised by Wilson, who was not particularly acquainted with him at that time: Wilson left Rome in 1755. In 1777 Hackert made a tour in Sicily with Richard Payne Knight and Charles Gore, and then he returned to the north of Italy with Charles Gore and his family. In 1782 he went to Naples and was presented to the king, Ferdinand IV., by the Russian ambassador, Count Rasumovsky. The king took great pleasure in the works of Hackert, and treated him with great kindness and familiarity; he used to style him Don Filippo. In 1785, after the departure of Count Rasumovsky, he appointed Hackert his principal painter, who settled with his brother from that time in Naples. They had apartments in the Palazzo Francavilla on the Chiaia, which they occupied until they were dispossessed by General Rey, the French commander-in-chief of Naples in 1799, who took possession of themselves and his house; he however treated the Hackerts with great kindness, gave them passports, and suffered them to depart with all their goods and chattels, with which they arrived safely at Leghorn. Hackert's salary was for a certain number, with his apartments free, both in Naples and at Caserta. In 1787 Hackert painted a large picture of the Launch of the Parthenope, 64, the first ship of war which was built in Naples, in 1785. It was engraved by his brother George, and was painted five other large pictures of Neapolitan scenes, which were all exhibited by some historical scene of interest: they are in the palace at Caserta. In 1788 the king sent Hackert to the East Indies, and the seaports of that coast, which he painted, from Manfredonia to Taranto. In 1790 he visited on a similar mission the coasts of Calabria and Sicily; the king equipped for him a small felucca called a swagetti, manned with twelve men well armed, for the express purpose; he was out about five months, from April to August inclusive.

Hackert lived, after his departure from Naples in 1799, about one year in London, where he removed to Florence, where he resided in a villa which he purchased in 1803, until his death in April, 1807.

Hackert's works are not remarkable for any particular quality of art: they are simple portraits or prospects in ordinary light and shade, and their beauty accordingly depends upon the local beauty of the scene. The detail is often lacking, and in these paintings of Italian landscapes of any particular scene the chief object of desire, his works are calculated to give perhaps complete satisfaction, except in the case of some fastidious connoisseur who might require something more minute, in which case there is a magnificent manner of his characterises his works generally. His drawings are extremely numerous, and his paintings are not rare; many of them have been engraved. He painted in oil, in encaustic, and in body wash, and engraved in mezzotinto, scappavia, a species of stippler. He also etched several plates.

Goethe has written a eulogist Life of Hackert, whose close imitation of nature delighted the German critic, and he has extolled him beyond his merits; while he compares Flaxman with Salatteli, and damnus his noble designs with the faint praise that they have some pretty ideas in them; he considers the Englishmen as the writers of the beginning of the 18th century.

(Goethe, Werke—Philip Hackert; and Winkelmann und sein Jahrhundert.)

HACKNEY-COACH. The derivation of the word Hackney,应用的class of public conveyances, has occasioned much speculation. Bailey, in his Dictionary, adoptes what appears to have become a popular notion, that the name is derived from the hackney, or small saddle of London; for which supposition however we find no plausible ground, but he adds, 'unless you would rather have it from the French Hackney,' which is a word of similar meaning.

Hackney-carriages, or Hackney-coaches, to the English nation, are a representation of the Latin equus, a horse, thus:—equus, ahus, ahuus, ahus, ahuus, hackney. Another conjecture derives it from an Anglo-Saxon word meaning to neigh, on the supposition that a lively horse, given to neighing, and which is the most likely in the hackney-carriages and Stage-carriages is further implied, rather than distinctly expressed, by the provision that nothing in the act shall extend or apply to any stage-coach used for carrying passengers only in the line of its specified route, at a certain fare (which is not regulated by act of parliament), for each individual passenger, being usually, though not invariably, dependent upon distance.

As far as can be gathered from such notices as the writer has met with, this class of public vehicles appears to have been originated in Scotland. In London, however, they have been much more in use, and in particular the hackney-coaches. London may be perhaps distinctly traced from notices in Macpherson's 'Annals of Commerce,' and in Anderson's 'History of Commerce,' of which work the early volumes of Macpherson, are reprinted with but few alterations. Under the year 1625 Macpherson, or rather Anderson, observes that 'our historiographers of the city of London relate that it was in this year that hackney-coaches first began to ply in London under the name of hackney-coach.' Under the year 1784 sedan-chairs appear, for the first time, to have entered into competition with hackney-coaches, the sole privilege being granted in that year to Mr. Sanders Duncombe to 'use, let, and hire' a number of 'covered chairs,' such as he represented to be in use in many places beyond sea, for a period of fourteen years. The objection was raised, that the inconvenience occasioned in the streets of the metropolis by the unnecessary multitude of coaches. In the following year an attempt was made to check the increasing use of the above accommodations by the prohibition of 'immense use of coaches' by a proclamation from the king (Charles I.) that no hackney or hired coach should be used in London, Westminster, or the suburbs, unless it was engaged to travel not more than four miles out of the same; and that each coach owner should constantly maintain four able horses for the royal service when required. Finding it impossible to prevent the use of so great a convenience, a commission war
issued to the master of the horse in 1837 to grant licences to fifty hackney-coaches in and about London and Westminster, and as many others as might be needful in other places in England, but in no place more than twelve horses. In 1852 the number of hackney-coaches daily plying in the streets was limited to 200; in 1864 it was increased to 300, allowing however only 600 horses; in 1861 to 400; and in 1864 to 700. On an act of the 9th year of Anne (c. 23) the number was to be increased to 800 on the expiration, in 1715, of the licences then in force, and 200 hackney-chairs were also licensed. The number of chairs was shortly increased to 300 by the act 12 Geo. 1. c. 12 to 400. In 1771 the number of coaches was further increased to 1000.

Notwithstanding this steady increase in the use of hackney-coaches, they were long regarded as public nuisances in a way which it is amusing to look back upon. Some curious details on this subject are given in Knight's 'London,' vol. i. p. 27, &c., from which it appears, by a quotation from a letter of Garrard, that completely lost sight of stand was established in 1834, by one Captain Bally, at the May-pole in the Strand. Even so late as 1860 Charles II. issued a proclamation against hackney-coaches standing in the streets to be hired; not on the very day it was to come into force, Pepys records that he got one to carry him home. The monopoly long enjoyed by the London hackney-coachmen produced great indifference to the interests of their customers. In 1823, only a few years to the year 1823, while that monopoly was undisturbed, hackney-coachmen appeared to have sunk lower and lower in the scale of efficiency. 'For some two hundred years,' observes Mr. Routh, in his 'History of the Stage,' 'the hackney-coach was the best vehicle in Europe for travelling, riding, the casualties more sedentary, the carriage through all its phases of dirt and discomfort; the springs growing weaker, the 'iron ladder' by which we ascended into its bony cavities, in its rattling galda, the cushions more redolent of distant smells, the glasses less air-tight.' So slow, also, were their movements, that it was almost hopeless to think of gaining time by riding in them.

While this was the state of things in London, a lighter kind of vehicle, drawn by one horse, had been brought into everyday use. In the year 1813, according to a paper on the 'Vehicular Statistics of London,' in No. 78, new series, of 'Chambers's Edinburgh Journal,' (to which we are indebted for many of the following particulars), there were no less than 1150 of these vehicles, which were called cabriolets de place. Efforts were made to introduce similar vehicles into this country, but, owing to a regard for the 'vested rights' of the hackney-coach owners, it was long found impossible to get licences for them. We feel the difficulty Moses, Bruck, and Rochet (the latter a member of parliament) obtained licences for eight cabriolets in 1828, and started them at fares one-third lower than those of hackney-coaches. The new vehicles were only by one horse only, and carrying only one passenger besides the driver, who sat in the cabriolet (or, as more commonly called for brevity, the cab), with his face. An improved build was soon introduced, by which the cabriolet was divided, so that the driver was separated from the fare; and with the rapid extension of this lighter class of vehicles, numerous varieties of construction have been introduced, in most of which the original model is almost lost sight of, but in which comfortable and safe accommodation, with complete shelter from the weather and separation from the driver, is provided for two, three, or, in a few cases, for four persons. The name 'cab' is still commonly applied to all hackney-cabriolets drawn by one horse, whether on two or four wheels. During the first few years of the employment of such cabs, their number was restricted to sixty-five, while the number of coach-licences was increased to twelve hundred; but in 1832 all restriction as to the number of hackney cabs was removed, and in the paper above referred to it is stated, on the authority of information received from the registrar of hackney-carriage licences, that the number of hackney-carriages licensed for use during the year ending January 4, 1845, was 2450, all of which, with the exception of less than 200, were cabs, or cabriolets. In the year ending May 1844, was 4927, besides 371 'watermen,' or 'attendants upon the 130 regular metropolitan coach-

While the changes above noticed have greatly benefited the public, there is reason to fear that the great increase of accommodation has not been accompanied by any elevation of moral character in the large class of men engaged in this business. Since the year 1822 hackney-carriage drivers have been required to deposit any articles which may be accidentally left in their carriage in the hands of the registrar of licences to whom the owners of the lost property may apply for its restoration, upon paying for the driver's time and trouble; and, incredible as it may appear, the estimated value of the property thus taken to the office in the first four years and a half after the introduction of this rule is estimated at 35,000l., while very few applications were made for property which was not thus restored. Of late years however the case has been very different, for while from 50 to 100 cases, or lost articles, have been taken to the office in twelve months, they are all of small value; and the applications made for lost property are at least fourteen times that number. To lessen the risk in reference to one very important part of the employment of hackney carriage business, the great railway companies which have terminated in London enter into arrangements by which a limited number of carriages, driven only by men of well attested respectability, are allowed to stand within their stations, to convey passengers arriving by the trains to their respective destinations, under a system of supervision so strict, that any case of misconduct or overcharge is almost certain to be brought home to the guilty party; and it is gratifying to know that this measure has proved productive of the best results in promoting honesty and civility among a class of men, which has been hitherto affected by the strictness of the licensing system, and by the various efforts made, especially by the agents of the London City Mission, for their education and religious welfare.

It is thought that in this class of vehicles the freedom of drivers leads to the (we believe universal) adoption of a system of remuneration which is not calculated to promote honesty and good feeling. It appears, the writer of the paper we have quoted above, 'that the drivers have no chance of being honestly dealt with, if they were to pay wages to their servants.' They therefore, 'adds, 'load the vehicles and horses at a fixed sum per day; and further, the men are expected to bring home the stipulated amount. Sometimes, in the dull season, they beg off for less, but it was remarked to us by the manager of the largest establishment of cabs in London, 'that in the dull season ever so prosperous, they never produce more than the stipulated amount, to make up for former deficiencies.' The experiment of paying liberal wages, and trusting to the honour of the men, is said to have been tried and found utterly impracticable. 'The average produce of each hackney-carriage to the proprietor,' according to our authority, 'may be about ten shillings and sixpence a day, to which, if about three-and-sixpence be added for cash and fares taken, the appropriation by the drivers in lieu of wages, the amount (of earnings or receipts) per diem is raised to fourteen shillings.' 'Hence,' he adds, 'we may conclude that there is spent daily by the London public for coach and cab hire 1712s., and yearly almost 800,000l.' Hackney-coaches were, according to Beckmann ('History of Inventions,' English edition of 1814, vol. i. p. 184), first established in Edinburgh, in 1738. According to a patent (p. 131) it appears they were first used at Paris in 1850, although, if this date be correct, he is wrong in stating that the use of hackney-coaches originated there. He attributes their introduction to Nicholas Savaugue, from whose residence, the Hotel S. Fiacre, such carriages took their common French name of fiacres. About 1869 a small kind of hackney carriage, resembling a sedan-chair on wheels, called a brouette or rouette, or sometimes, by way of derision, a viniogrette, and drawn by men, was brought into use. Cabriolets, as above stated, appear to have originated in Paris.

For an abstract of the law relating to hackney and stage carriages, duties, licences, &c., see METROPOLITAN STAGE CARRIAGE. P. C. S. HADRAMAUTE. [ARBIAH, P. C. S. AND P. C. S.] HEMANTHUS. [AMANTHUS, P. C. S.] HEMATOCoccus (from alga, blood, and sodes, a grain), a genus of plants belonging to the natural order of Algae. It is characterised by being composed of either being oval or spherical, cells, in one or more concentric vessels, or membranes, multiplied either by division or by granulae formed within the parent cells. Several of the species of this genus are terrestrial. One of the first observed was the H. saugnutus, which, like the red-snow plant ('Protococcus nitida'), has its cells coloured red; hence the generic name. Several of the species however
HAGUE, ALLIANCE OF THE. As the general war which was terminated by the Peace of Paris in 1697 [T.C.X, 297] was preceded by what is called the First Grand Alliance, formed between the Emperor and the United Provinces, 12th May, 1689, and joined by Great Britain 9th December following, so the next general war, which broke out in 1702, was concluded by the Second Grand Alliance, or Alliance of the Hague, concluded at that town between the Emperor, Great Britain, and the United Provinces, 7th September, 1701, and subsequently joined by Portugal and other European powers. Its object was to resist the seizure of the Spanish crown by the French king Louis XIV. for his grandson the Duke of Anjou, who nevertheless eventually became King of Spain, by the title of Charles III. The Alliance of the Hague was the result of his personal combination arranged by William III. of England, who died 8th March, 1702; and war was declared against France by Queen Anne 4th May following. [PARTITION TREATIES, P.C., xv, 292.]

HAGUE, LAURENCE. 17th century, a Protestant minister, was educated at the University of Marburg. In 1678 he removed to Sweden, where he became a sort of spiritual father to the King, and lived to the end of his reign. He was kind and benevolent to the Swedes, and it is related that at times he kept open house for the poor. He never married. His writings are numerous, and were mostly anti-Catholic. He died at Stockholm in 1720. His writings are numerous, and were mostly anti-Catholic. He died at Stockholm in 1720. He died at Stockholm in 1720.

HAGUES. Town in France, administratively a commune in the department of Doubs, district of Besançon, arrondissement of Besançon, canton of Corbigny. It is located in the Morvan massif, at an altitude of 300 m, 12 km northeast of Besançon. It is a wine-producing area, producing white wines and a local hard cheese. It is also known for its black truffles. The town has a population of approximately 13,000.

HAGUES, Martin. 18th century, a French physician, was born at Huy in Hainaut, and studied at Louvain. He later moved to Paris, where he became a doctor in 1744. He is known for his work on the treatment of scurvy and other vitamin deficiencies. He died in Paris in 1791.
out his great work, the 'Organon of the Healing Art,' in which he developed his western system to the exclusion of 'Homoopathy,' by which it has since been distinguished. [HOMOPATHY, F. C. S.] In 1811 the first part of the 'Materia Medica Pura' was published, and still it lists the names of the medicines. The apothecaries of that city, however, rose against him, and appealing to an old law long dormant, that forbade a physician to dispense his own prescriptions, they eventually, after some litigation, forbade him in 1828, to retire for practice, when the Duke of Anhalt Cöthen offered him an asylum in his dominions, with the enjoyment of those privileges of which he had been deprived at Leipzig. He was again his sojourning at Cöthen, in the year 1829, that he published in four volumes his work on 'Chronic Diseases, their Peculiar Nature, and Homoepathic Cure.' In the year 1829 the disciples and adherents of Hahnemann were struck with the idea of marking their attachment to the new system and their esteem for its founder. It bore on the face the head of Hahnemann, with the inscription, 'Samuel Hahnemann natus Minnea P. x April et Annis. Erlangeri x Augusti MDCCCLXXII.' On the reverse, in the centre, 'Similia Similibus; the inscription, 'Medicinae Homoepathicae Auctori, Discipuli, et Amici, P. x Augusti MDCCCLXXXII.' His adherents had at this period greatly increased, and he enjoyed a very extensive practice among his own countrymen and foreigners.

Having been a widower for some years, he married in 1835 a French lady, Mme. de Herville, who had visited Cöthen for the benefit of his advice, and at her desire he removed to Paris. In commemoration of his arrival in the French capital, an admirably executed medal by David was struck, in bronze, silver, and gold, bearing on its face the head of Hahnemann, with the inscription 'Samuel Hahnemann.' On the reverse, in the centre 'Similia Similibus curatur,' engrafted by a snake; the inscription, 'Les Homœopathes de France à leur Maître.' N° 6 à Meisen le 10 Avril, 1752, venus en France le 25 Juin, 1835.' He remained at Paris in the active exercise of his profession, and surrounded by numerous followers, till the day of his decease, which took place on the 2nd July, 1843, in the eighty-ninth year of his age.

Hail. [Snow, F. C., p. 165, col. 2] [Snow, F. C., p. 166.] The principle of insurance has been recently applied to indemnify persons for the very heavy losses sometimes occasioned by these meteorological phenomena, both by the Royal Farmers' and General Insurance Institution and by a society connected with the Norwich Union Insurance Company. The uncertainty which exists in reference to the occurrence of these frequently calamitous storms in any particular locality, and the circumstance that, while no human agency can forestall or prevent them, it is utterly impossible to produce them by fraud, appear to render such casualties peculiarly fit, so soon as observation and experience shall have established accurately the average risk, for the consideration of a principle which has long been applied to casualties of a nature less uncertain, more easily provided against, and which afford greater opportunities for deceit and imposture. Several hail-storm insurance societies have published chronological lists of the most remarkable hail-storms in this country during the present century, which present an array of destructive calamities far exceeding what might have been expected from their rarity. It is curious also to observe that they appear to have increased in frequency of late years. In one case, which we select solely from the more circumstantial in which the details are given, many farms of considerable extent were completely destroyed by hail-storms in Hertfordshire, Middlesex, and Essex; the damage done upon a space of 3487 acres in the last-mentioned county alone was estimated at $14,574, or about 42. 3s. 7d. per acre, upon an average. It is stated that this was the third time within a period of thirty years that the crops in the northwestern part of that county had been destroyed in like way. During the great hail-storms of the months of July and August, 1843, by which immense damage was done in Cambridgeshire, Norfolk, Suffolk, Essex, Hertfordshire, Berkshire, Kent, Oxford, Dorset, Gloucestershire, and Yorkshire, several cases of individual loss amounted to upwards of 2000L. The breaking of glass in windows and skylights, and more especially in conservatories and hothouses, is one of the most frequent incidents inflicted by hail-storms; the masses of ice which fall being sometimes sufficient to demolish the wooden framework also. Such extraordinary cases of devastation will be fully accounted for if it be considered, that, as it is stated in a paper issued by the Farmers' Insurance Institution, on the authority of 'Leslie's Elements,' hail-stones having a diameter of two inches, a size which has been exceeded in several well-authenticated cases, will fall with a velocity of 1184 feet in a second, or more than 14 miles in a minute. On the 19th of May, 1806, it is estimated that 20,000 panes of glass were broken in London alone, besides great damage being done in fields and gardens, and the foliage and branches of trees being stripped. An ice-lash of pans is supposed to have been broken in the northern suburbs of the metropolis on the 30th of July, 1826. Hail-storms of from six to eight or nine inches in circumference are frequently mentioned in the periodical literature of that year, and this list referred to, which are compiled from contemporary publications; and on the 3rd of August, 1824, when the eastern part of Suffolk was visited by violent hail-storm, by which bowls and game, as well as glass and crested pigeons, were extensively destroyed, the ice accumulated in some places to a surprising depth. In many cases a considerable extent of ground has been covered to the thickness of several inches. It is worthy of remark how very large a proportion of the destructive storms recorded have occurred in the months of June and July. Without noticing the cases in which two or more storms which occurred about the same time are alluded to as one, which would render this proportion yet more remarkable, the cases recorded in the above-mentioned lists occurred as follows. We have, of course, taken care to omit those storms of which two separate accounts are given in the month of January. February 1. March 3. April 4. May 7. June 10. July 17. August 19. September 27. October 0. November 0. December 0.

In the article 'Hail,' in Brande's 'Dictionary of Literature, Science, and Art,' are some curious facts collected from various authorities, from which it appears that hailstones have been found weighing from five to twelve or thirteen ounces, and of all sizes up to about fourteen inches in circumference; the largest being frequently of very rugged and irregular form, resembling portions of large cabbages. An ice-lash of pans is pieces rather than balls of ice. 'Hail,' according to this authority, 'usually precedes storms of rain, sometimes accompanies, but never or very rarely follows them, especially if the rain is of any duration, and the cessation of its continuance is always very short, generally only a few minutes, and very seldom more than a quarter of an hour.' The writer of the article referred to further remarks, that 'the close from which hail is precipitated appears to be of very considerable extent and depth, inasmuch as they produce a great obscurity. It has been remarked,' he adds, 'that they have a peculiar grey or reddish colour, and their lower surfaces present numerous protuberances, while their edges exhibit deep and numerous indentations.' Hail is said to be always accompanied with electrical phenomena, and it is generally believed that such are the cause of its formation. The numerous list of hail-storms published by the Farmers' Insurance Institution, which gives references to authorities, and in many cases minute details of the damage done, appeared in the advertising sheet of the 'Farmer's Almanac' for 1845.
HAINES is the name given to a river lately discovered in the eastern parts of Africa, in those countries which are comprehended on our maps under the name of Zanguebar. The eastern coast of Africa, from the equator northward to 6° or 7° S. latitude, consists of deserts, sand-hills, and a complicated wilderness; its aspect from the sea is very promising, the coast south of Magadoxo presenting only an uninterrupted series of sand-hills, whilst that north of Magadoxo is formed by immense sand-hills and deserts. But Lieutenant Christopher, in 1843, discovered, that at the back of the sand-hills there is a considerable river, which waters an extensive valley, filled with alluvial soil and exhibiting a great degree of fertility: this river, whichprobably originates in the high countries which surround the most southern affluents of the Abal, or eastern branch of the Nile; but as the intervening countries have never been visited by Europeans, we are unable to determine whether any of the rivers rise in these countries and which of them sends its waters to the Haines. Lieutenant Christopher was informed that north of 4° S. latitude the river is already considerable. He visited it at Girédi, a town situated twenty-two miles north-west of Magadoxo, inhabited by more than 7000 individuals, and surrounded by extensive fields, on which Indian corn and millet yield such abundant crops that large quantities of them are sold for exportation and consumed by the natives. The river here is about 200 feet wide, and too deep to be forded in the dry season. From this place the Haines runs nearly parallel to the coast for ten or twelve miles; it then bends eastward for four miles, and numerous villages are found on its banks, surrounded by extensive fields irrigated from the river. The volume of water carried away decreases considerably by this irrigation; but at the most southern point where it was seen by Lieutenant Christopher, which was due north of the town of Brava, where it was only from 70 to 150 feet broad, but from 10 to 15 feet deep. From this place the river continues in a south-western direction, and terminates, according to the statement of the natives, in an extensive lake said to be inestimable. This lake is about sixty miles from the eastern banks of the river Jubb or Gavindo, and perhaps not so much as a mile from the coast. The alluvial soil of the broad alluvial tract traversed by the Haines River are a mixture of Somauss, Galla, and negroes, among which a small number of Arabs are settled. It appears that the greater part of them are Mohammedans. The chiefs of the country are Somauss, but their power is limited, as it appears, by a kind of aristocracy.

HAL. (Halle, P. C. S.)

HALE'SIA (named in honour of Stephen Hales, D.D., author of 'Vegetable Statics,' Sec.), a genus of plants belonging to the family of the Compositae, to which belong the corolla ventricosum campanulata, with a 4-lobe erect border; the stamens 12 to 16; filaments combined into a tube at the base, and adnate to the corolla; the anther oblong, erect, 2-celled. It is: a herb or a shrub; the flowers single; the fruit a drupe, which is dry, oblong, with 2-4 winged angles, terminated by the permanent style; the seeds 1-seeded, with the seeds at the bottom of the cells. The species are trees with alternate serrated leaves, and lateral fascicles of pedicellate drooping white flowers. This genus has been made the type of an order Haleasieae by D. Don, who is followed by Link and others.

H. heteropetala, common Snow-drop tree, has ovate, lanceolate, acuminate, sharply serrated leaves; the fruit with four wings. This plant is a tree, growing from 15 to 20 feet high, and is native of South Carolina. It has fine white flowers from 9 to 10 in a fascicle, drooping and resembling those of a snowdrop. The wood is hard and veined. It is one of the hardest and also one of the handsomest of the American deciduous trees. The rate of growth for the first five or six years is from 12 to 18 inches a-year. It ripens its seeds freely in this country, and it may be propagated from these or imported seeds. There is another species, H. diploa, which is a native of South Carolina, but does not attain so great a height as the last, and has much larger flowers. H. porrecta is a native of Florida, and is supposed by some botanists to be merely a small flowered variety of the first. They will grow in any good soil, and may be propagated by slips from the root, as well as from seeds.

(Don, Gardner's Dictionary; London, Encyclopedia of Trees and Shrubs."

HALFORD, SIR HENRY, was born on the 20th of October, 1766, and was the son of Dr. James Vaughan, physician to the Infirmary at Leicester, and author of 'Observations on Hydrophobia, on the Case of Cantharides in Paralytic Affections.' Sir Henry received his education at Eton, and was afterwards admitted at Christ Church, Oxford; he graduated in Medicine at Cambridge in 1794, and was elected a fellow of the College of Physicians in the same year. Having been well introduced into the practice of his profession, but Lieutenant Christopher, in 1843, discovered, that at the back of the sand-hills there is a considerable river, which waters an extensive valley, filled with alluvial soil and exhibiting a great degree of fertility: this river, which probably originates in the high countries which surround the most southern affluents of the Abal, or eastern branch of the Nile; but as the intervening countries have never been visited by Europeans, we are unable to determine whether any of the rivers rise in these countries and which of them sends its waters to the Haines. Lieutenant Christopher was informed that north of 4° S. latitude the river is already considerable. He visited it at Girédi, a town situated twenty-two miles north-west of Magadoxo, inhabited by more than 7000 individuals, and surrounded by extensive fields, on which Indian corn and millet yield such abundant crops that large quantities of them are sold for exportation and consumed by the natives. The river here is about 200 feet wide, and too deep to be forded in the dry season. (Don, Gardner's Dictionary; London, Encyclopedia of Trees and Shrubs."

HALFORD, SIR HENRY, was born on the 20th of October, 1766, and was the son of Dr. James Vaughan, physician to the Infirmary at Leicester, and author of 'Observations on Hydrophobia, on the Case of Cantharides in Paralytic Affections.' Sir Henry received his education at Eton, and was afterwards admitted at Christ Church, Oxford; he graduated in Medicine at Cambridge in 1794, and was elected a fellow of the College of Physicians in the same year. Having been well introduced into the practice of his profession, but
Mouse and the City Mouse.' It is for the greater part a dialogue in prose, apparently in imitation of the Duke of Buckingham's 'Rehearsal,' with the parody in verse of portions of the 'Odes of Horace.' Lord Swithinbury or Lord Swithin are said to be Prior's, as may very well be believed; it is not, however, printed in the common collections of his poetry; but it is preserved in the 'Supplement to the Works of Prior,' vol. i. pp. 47-82, under the head of 'Additions to the Works of the Earl of Halifax.'

Montagu appears to have some time before this entered upon his career of administration. Just before, in his 'Lives of the Poets,' merely says that 'he signed the invitation to the Prince of Orange, and sat in the convention;' but his signing the invitation to the Prince would seem to imply that he had occupied some public office, and he, therefore, supposes the Charles Montagu who is set down as one of the members for the city of Durham in James II.'s parliament which assembled 15th May, 1685. In the convention parliament he sat for Malton; and he was returned for the same place to the next parliament, which met in March, 1689. It is stated to have been about the time of the Revolution that he married the Countess Dowager of Manchester: she was Anne, widow of Robert, third Earl of Manchester, and daughter of Sir Christopher Yelverton, Bart.

According to Johnson, it was his intention when he formed the Whig party to make him a member of the council of ten, in his purpose he purchased for 1600l. the place of one of the clerks of the council. He was also fortunate in his next poetical performance, 'An Epistle to Charles, Earl of Dorset, occasioned by his recent victory, the deliverance of the battle of the Boyne,' for which Klug William, to whom he was introduced upon the occasion by Dorset, is said to have bestowed upon him a pension of 500l. A report of his majesty's, who was then in the Dilapidation of his fortune, as a mouse is said to have replied that he would make a man of him, is upon good grounds accredited by Johnson. His Epistle on the Victory of the Boyne, which extends to above two hundred lines, is Montagu's greatest effort in verse.

The rest of his history is that of a political character, and only a patron of poets. Johnson relates a well known anecdote of him: in 1697, in the midst of which he is said to have fallen into confusion, and then, when he recovered himself, to have ingeniously turned the circumstance into an argument for what he was urging, the allowance of counsel to the prisoner. There is no notice of this speech in the Parliamentary History. He had already, however, raised himself by his speaking to great distinction; and on the 21st of March in this year he was taken into office as one of the lords of the Treasury. Burnet first notices him as making a great figure in the House under date of the year 1693. 'He had,' he says, 'great vivacity and clearness, both of thought and expression; and in his petticoat, which he continued still to encourage in others when he applied himself to more important business. He came to have great notions with relation to all the concerns of the treasury, from public funds, and became more and more master of new and better methods: he showed the error of giving money upon remote funds, at a vast discount, and with greatpremiums, to raise loans upon them; which occasioned a great outcry at the sums that were given, at the same time that they were much shrunk before they produced the money that was expected from them. So he pressed the king to insist on this as a maxim, to have all the money for the service of a year to be raised within that year.' But part of this applies to what was done by Montagu after he became chancellor of the Exchequer, to which office he was appointed on the 1st of November, 1694, to which he was reappointed in 1697, he conjointed that of first lord of the Treasury. In 1696 and 1697 he obtained great credit by his management of the operation of the general receival of the silver money. It was in the latter of those years that, to supply a temporary circulating medium, he contrived what are called Exchequer Bills, the convenience of which species of paper, both for the government and for the public, is 'acknowledged by Money of Montagu's Exchequer bills, however, were for some much lower than any for which such bills are now issued. After he became first lord of the Treasury he was appointed at one time as confidential secretary to the king, at which, in the House of Commons, on the 24th July, 1698, and again in May, 1699. 'In the House of Commons,' says Burnet under the year 1698, 'Mr. Montagu had gained such a visible ascendancy over all that were zealous for the king's service, that he gave the law to the rest, which he did always with great spirit, but sometimes with too assuming an air,' which, subjines Mr. Speaker Onslow, in a note, 'did him infinite hurt, and lowered at last his credit very much in the House of Commons.' Lord Hardwicke, in the speech of the same passage, affirms, that for two sessions together Montagu did not exert himself in the House (for what reason Hardwicke does not explain). To have friends to take the lead, even while he continued in the king's service. He is also asserted to have lost some credit about this time, and to have been thought to have behaved meanly, by staying in the House, in the course of debates on the loans, grants, some information which had been communicated to him in confidence. On the modification of the ministry in November, 1699, Montagu was removed to the authorship of the Exchequer, and the new of first lord and commissioner were given, the former to Lord Tankerville, the latter to Mr. John Smith. In the end of the following year, on the acquisition of the complete ascendency by the Tories, he was removed from the House of Commons by being created Baron Halifax (with remainder, failing his own issue male, to George Montagu, son and heir of his eldest brother Edward Montagu). This, however, was overturned upon the accession of the new master of the House of Commons. The title of Marquis of Halifax had just been extinct by the death of the son of the first marquis [SAYLES, GREGORY, P. C.]; and it fell to Lord Halifax, in a note in the 'State Trials,' ii. 108, Montagu took his title in grateful remember- nace, as he pretended, of the old marquis, who, Dartmouth says, had first brought him into business by recommending him to the clerk of the commons. 'He generally thought more out of vanity (of which he had a sufficient share), in hopes of raising it to such a high degree as his benefactor had done.'

Lord Halifax was impeached by the new House of Commons in April, 1701, along with Lord Somers [P. C., xii. 217] and the Earls of Portland and Orford. The question was carried in the House by a vote of 186 against 154; but the impeachment was not prosecuted, and the charges were dismissed by the Lords. (See the proceedings in the 9th volume of the 'Parliamentary History,' and in the 14th volume of the 'State Trials.') 'The State Trials' exhibited against Halifax were six in number:—1, That he had directed a grant to the value of 13,000l. to pass to Thomas Fanilton, Esq., in trust for himself, out of the forfeited estates in Ireland; 2, That he had received to his own use 1000l. a year out of the said grant; 3, That, while chancellor of the Exchequer, he had obtained and accepted of several other beneficial grants to or in trust for himself; 4, That in 1697 he had procured a grant to Henry, gent., in trust for himself, of wood from the Forest of Dean, to the value of 14,000l.; 5, That while he was chancellor of the Exchequer he had obtained for his brother Christopher the office of auditor, in trust for the use of the Exchequer, and that his brother had advised his majesty to enter into the two partition treaties. [P. C., xvii. 285.] In his answer Halifax maintained that the grants to the Irish of the Forest of Dean were legal, and were also not of the value charged; that there was nothing wrong in procuring the auditorship of the Exchequer for his brother, to be held by him till he should himself be ready to step into the office; and that, as to the partition treaty, he was rather opposed to them in favour of them.

In 1703, after the accession of Queen Anne, Halifax was again attacked by the Commons on the charge of having been guilty of breach of trust in the management of the public accounts while he was chancellor of the Exchequer; and an address was voted to the queen requesting that she would be pleased to give directions to the Lords general to prosecute him. But he was again protected by the Lords; and after some altercation between the two houses the matter was dropped. The proceedings are given in the 'Parliamentary History,' vi. 127, &c. Though out of office during this reign, he continued to take an active part in the debates of the House of Lords, especially distinguishing himself in 1707 in the defence of the 'Sect of Nonconformists.' He, however, complains (note on Burnet, 'Own Times,' i. 431) that he and Lord Wharton brought up a familiar style with them from the House of Commons, 'that has,' says his lordship, 'been too much in vogue in the House of Lords, where everything formerly was managed with great decency and good manners.' To Halifax also belongs the credit of having first moved, and taken the most active part in, the project for the purchase of the Cotton manuscripts and the
establishment of a public library, out of which eventually
eceased the British Linen Company. His relations always kept up a connection with the Hanoverian
family, Lord Halifax was found, on the death of Queen Anne,
to be one of the nineteen persons appointed by the new king
to meet with the Duke of Cumberland to consider his legitimate
right to the throne; and the Duke, in the event of his
state till his majesty should come over. (On the 14th of
October, 1714), he was raised to the dignities of Earl of Hal-
ifax and Viscount Sunbury, and was restored at the same
time to his father post of first lord of the Treasury, his office
being that of auditor of the Exchequer being given to his nephew. But he
died of an inflammation of the lungs on the 19th of May in
the following year. He left no issue, so that his earldom and
viscounty came to an end; but he had left his son a
fortune according to the limitation by his nephew George Mon-
taggi, who a few weeks after was made Earl of Halifax and
Viscount Sunbury by a new creation. The son of the second
Earl of Halifax died without issue in 1779, when all the
honours became extinct.

Halifax was one of the most consistent of the Whig party
to whom we are indebted for the Revolution, the Hanoverian
Succession, and the Union with Scotland. It is evident also
from the detail that has been given, that he was a person of
great general ability. But he was much more a man of action
than of any remarkable powers of thought; and what he was
of most value, was the value of his character. As a list of his pieces is given by Walpole in his ' Royal and Noble Authors.' His character as a patron of literature has been
determined to be greater than that of the Essayist; and, in the nature
Full-blown Buo,' by Pope, in his 'Prologue to the Satires.'

HALL, REVREBEND ROBERT, was born the 2nd of
May, 1764, at Askby in Northumberland, where his father was,
the same year. He was educated at the Free Church of
Corporation of Particular Baptists. He had come from Northum-
berland, where his forefathers belonged to the class of yeo-
manry; and he is stated to have been a man, though not of
much learning, of considerable native power of mind. He
is the author of several short religious publications: one of
which, entitled ' A Hap to Zion's Travellers,' was several
times printed.

The most interesting of this notice was the youngest of fourteen
children. It is related that he was two years old before he
learned to speak; but after this, the progress he made in all
branches of his education was very rapid. Though the cir-
cumstances are obscure, it is an evidence of the imprecation he
had made by his precocity—that he was only eleven years
old, a fellow-clergyman of his father's (Mr. Beoby Wallis, of Kettering), to whom he had been taken on a visit,
simply set him to preach to a select auditory assembled in
his house. His gift of ready expression had, it would appear,
already strongly developed itself. He used to attribute much
of his early intellectual excitement to the conversation of a
metaphysical author, when he was at his native village, a member of his
father's congregation.

He lost his mother in 1776, and it appears to have been
sent to be sent to be
Northampton, kept by the Rev. Dr. John Ryland. Here
he remained for a year and a half, after which he was placed, in
October, 1778, at the Bristol Academy, with the view to his
becoming a Baptist clergyman. It is the practice, it seems, for such students to commence preaching before they have finished their education; and Hall was, as it is expressed, set
apart as a preacher by his father's congregation in August,
1780. In the autumn of 1781 he was selected by the authori-
ties of the Bristol Academy to be sent to King's College,
Aberdeen, on what is called Dr. Ward's exhibition; and here
he studied for the usual period of four winter sessions; preach-
ing, at least occasionally, in the intervening summers. It was
at Aberdeen that Hall and the late Sir James Mackintosh,
then also a student at King's College, became acquainted.
They bore a close resemblance in intellectual character, in
their powers of mind as well as in their tastes, and the inti-
macy which now sprang up between them led to an affec-
tionate friendship, which lasted while they both lived.

Hall did not finally leave Aberdeen till May, 1785; but he
had attended occasionally, in the intervening summers. It was
at Aberdeen that he made a considerable acquaintance with
the regular pastors of the Baptist congregation at Broad-
mead, Bristol, in association with Dr. Caleb Evans; and in
August, 1785, he was also appointed by the Bristol
Academy. His father died in 1791, and the same
year a difference with Dr. Evans led to his removing from
Bristol and accepting an invitation to become pastor of the
Baptist congregation at Cambridge on the departure of the
Rev. Robert Robinson to be successor to Dr. Price at
Birmingham.

He was already acquired considerable celebrity as a
preacher, but it was not till now that he appeared as an
author; and the impulse that sent him to the press was rather
political than theological. In first instance, then we are to reckon
amongst the anonymous contributions to a Bristol newspa-
paper in 1786-7 was a pamphlet entitled 'Christianity con-
sistent with a Love of Freedom, being an Answer to a Sermon
preached in the Baptist church at Broadmead.' In this
moment of the most ardent minds of that day, he had been strongly excited and
carried away by the hopes and promises of the French
Revolution, and he appears to have retained his first faith without
much alteration in its frame. He met the popular pamphlet, entitled 'An Apology for the Freedom of
the Press, and for general Liberty, with Remarks on Bishop
Horsey's Sermon preached 31st January, 1785.' This
was largely diffused, and brought him much reputation. The
impression that had been made upon him, however, by the
irresistible character of the French revolutionary movement was
indicated in his next publication, ' Modern Infidelity consid-
ered with respect to its Tendency to Social Reform.' It
was the publication of this able and eloquent
sermon which first brought Hall into general notice. From
this time whatever he produced attracted immediate attention.
The Socinian press was not over 1002 for another on the Peace, which also brought him great reputa-
tion.

In November, 1814, Hall was visited by an attack of
sickness, the violence of which did not last long, but from which
he did not entirely recover for some years. His state of
health made it necessary for him to resign his charge at
Bristol, when in January, 1807, he became minister of
the Baptist chapel in Harvey-Jaye, Leicester, and this situa-
tion he held nearly twenty years. He married in March,
1808. At last, in 1826, he removed to the pastoral care of
his old congregation at Broadmead, Bristol; and here he re-
mained till his death, which took place at Bristol, on the 31st
of February, 1831.

Besides occasional contributions to various dissenting perio-
dal publications, Hall published in 1788 an account of
the last twenty years of his life, which, along with those
already mentioned, have since his death been collected and
reprinted under the title of 'The Works of Robert Hall,
A.M., with a brief Memoir of his Life by Dr. Gregory, and
Observations on his Character as a Preacher by John Foster;
published under the superintendence of Olinthus Gregory,
LL.D., professor of mathematics in the Royal Military Aca-
demy,' 4 vols. 8vo., London, 1831-2. It was intended that
the life should have been written by Sir James Mackintosh,
but he died (in May, 1832) before beginning it. Dr. Gre-
gory's Sketch, from which we have quoted the materials of this account, contained in the last of the six volumes.
The first contains sermons, charges, and circular letters (or
addresses in the name of the governing body of the Baptist
church) of those preached in the Baptist churches, in the
Union; two parts, 1816; and another entitled 'The Ess-
tial Difference between Christian Baptism and the Baptism
of John' (a defence of what is called the practice of free
communion), in two parts, 1816 and 1818; the third, political
and miscellaneous tracts, extending from 1791 to 1836, and
also the Bristol newspaper contributions of 1786-7; the fourth
reviews and miscellaneous pieces; the fifth, notes of sermons,
and letters. The sixth, including Dr. Gregory's memoir, con-
tains Mr. Foster's observations, and notes taken down by
friends of twenty-one sermons.

Hall was a man of many virtues, and of intellectual powers
which placed him in the first class of men of talent. His
acquirements were very considerable, and he appears to have
kept up the habits of a studious man to the end of his life.
But the great temporary impression that he made as a preacher
and as a writer is to be attributed chiefly to his general fervent
and fervour of mind, and not much to any higher or rarer faculty.
He was more of an orator or of a rhetorician than of a thinker.
His greatness lay in exposition and in the force of his
eloquence; and this force of eloquence was rather flowing and de-
corative than either imaginative or impassioned. His mind was
not in any sense an original or creative nor even a sublimate one; it
was philosophical, but only by seeing, and not by hearing or
the volumes of his writings, with all their general finish and
eloquence, and occasional brilliancy, although they may preserve
his name from being forgotten, will not greatly interest pos-
terity. They do not contribute anything to the world's stock
of thought or even of knowledge; and are therefore nothing more than a record or memorial of what their author was.

HALL, BASIL, CAPTAIN, R.N., was born at Edin-

burgh in 1788. His father Sir James Hall, Bart., of Dun-
glas, was President of the Royal Society of Edinburgh. He

was a native of the Island of Islay, and was ad-

mitted to the rank of commander; and in 1817 he was made a

post-captain. The opportunities which the naval profession
affords both for scientific pursuits and the study of men and

manner. Some circumstances happened in Captain Hall's case to

lead him into scenes of more than usual interest; or perhaps

it would be more correct to state that his eager and indefatigable
pursuit of knowledge induced him to seek every means of
extending the sphere of his observations. In 1815, when serving
commander of the Thetis on the East India station, he accom-

panied Sir Samuel Hood, the admiral, in a journey over the greater part of the island of Java. Soon after the return to England he was appointed to the command of the Lyra, a small gun-brig, in which he accompanied the expedition which took out Lord Amherst as ambassador to China. While the ambassador was pursuing his journey inland to Peking, Captain Hall in the Lyra, he sup-
porses that one of the principal of which are the models of the sculptures for the pedestal of the Glyptothek, representing Fallas Exagene ('Ephesia, the 'worker'), from a design by Wagner; the six

column stations in the interior of the Glyptothek hall, representing

necessarily Hephastus, Prometheus, Dædalus, Phidias, Pericles,

and Hadrian; and the Caryatides of the royal box of the great

theatre at Munich; besides a basso-relievo in the interior of the

Pergamon temple at Berlin. There are in the library of

the Fall of the Giants; and many busts of eminent men, some

of a colossal size. He executed the bust of William III. of

England for the Walhalla. He died in 1826, aged only thirty.

(Nagler, Allgemeines Künstler-Lexicon.)

HALO is a circular band of faintly coloured light which is

occasionally seen surrounding the disk of the sun or moon at a
distance from them which varies from about one to four degrees.

It is the greatest of all the phenomena of the sun and moon, for

whereas the other phenomena are usually apparent only for a

short time, and usually at great distances, the halo is a daily

phenomenon, visible even on the plainest days. The most

beautiful and the most frequently observed is the lunar halo.

When a mist or a thin cloud is between the sun or moon and

a spectator, there is frequently observed an ill-defined circle of
coloured light immediately surrounding the disk of the

luminous body; this is called a corona; it sometimes appears

when a halo is also seen, but it is more commonly observed

without such accompaniment. The solar corona generally

consists of three concentric bands variously coloured; and in

one which was seen by Newton the colours of the three bands

were successively, proceeding from the sun outwards, blue,

white, and red; purple, blue, green; and pale red; pale blue

and pale red. He stated that the angular diameter of the outer

band was about six degrees. The corona are supposed to be

produced by the refractions of light in the globules of water

which are suspended in the atmosphere between the spec-

tator and the luminous body.

It may be observed in this place that images of the sun

have been occasionally seen as if by reflection from some cloud,

the sun being near the horizon: these are called anstheia; and

Mr. Swinton has seen an anstheia, near the top of a

mountain, details of experiments made with an irreversible

Pendulum in South America and other places for determining

the Figure of the Earth; Observations made on a Comet at

Valparasio. The above three papers are published in the

Transactions of the Royal Society. A Sketch of the Pro-

fessional and Scientific Objects which might be aimed at in a

Voyage of Research. A Letter on the Trade Winds, in the

Appendix to Daniel's Meteorology; with scientific papers in

Brewster's Observations, Jameson's Journal, and the Encyclopedia

Britannica.

Captain Basil Hall having been unfortunately seized with

mental alienation, was placed in the lunatic asylum at Hoxton,

Portsmouth, where he died on the 19th of September, 1844.

HALLE, a flourishing town with a population of above

5000 inhabitants, is situated on the river Sene, in the pro-

vince of South Brabant, 14 miles south-west of Brussels. The town has several breweries, distilleries, tanneries, saltporks, and a paper-mill. It is cele-

brated for the manufacture of beautiful articles of wood, of

which considerable quantities are exported.

(Hassel, Handbuch; Canabich, Lehrbuch; Stein, Hand-

buch, by Hirschelmann.)

HALLER, JOHANN, a distinguished German sculptor,
born at Innsbruck in 1729. He studied in the academy

of Munich, and in his third year obtained the prize in sculp-

ture, for a statue of Thracus raising the Rock to discover the

Sandals of his Father. He executed many works in Munich

for the present King of Bavaria, both as carver and painter.

Of which considerable quantities are exported.

(F.)
some intermediate reflection; or after two refractions with two intermediate reflections. The index of refraction in ice being 1.31, and the prisms equaliteral; it may be proved that, in the first case, the false sun will appear to be at a distance from the true sun equal to 142 degrees, and in the latter case at a distance equal to 62 degrees.

Halos are frequently accompanied by a horizontal ring or band of whitish light passing through the sun or moon, appearing to ascend as the luminous rise, and having its apparent semi-diameter equal to the zenith distance of the latter; and at times a similar band appears in the direction of a diameter perpendicular to the horizon. At the intersections of these bands with the halo (but in a few instances a little beyond such intersections) are sometimes seen images of the sun or moon, which are ill defined and less bright than the true disk of the celestial body, or else the halo is formed about the sun, are called parhelia; and when about the moon, parheliac. Occasionally also segments of circles, or branches of curves of contrary figure, proceed from these images of the sun or moon so as to assume the appearance of wings or tails.

Many remarkable phenomena of this kind have at various times been observed: in the History of England, by Matthew Paris, there is a description of a halo which is stated to have been seen in the year 1233, on the borders of Herefordshire and Worcestershire; it is related that on each side of the halo was a semicircle which intersected the halo in two places; and that at the four intersections were as many false suns. In 1868 Rothman observed at Cassel, soon after sun-rise, a false sun above, and one below the true sun, all being in one vertical line; and in 1890 Belcher observed a remarkable halo at Rome. In 1600 Heredia, at Danzig, observed a single halo, and in 1681 a double halo; the former was accompanied by two false suns at the extremities of a horizontal diameter; and another at the upper extremity of a vertical diameter. In the last-mentioned year Heredia observed also a halo with two parhelia and a double corona about the body of the moon.

Dr. Halley observed a halo with parhelia in 1702; and a very remarkable one was seen by Sir Henry Englefield at Richmond, in 1892 (Journal of the Royal Institution, vol. ii.).

Besides these, many such phenomena have been observed in Europe, in the United States, and in Canada; and Captain (Sir Edward) Parry observed and measured several during his voyages to the arctic regions.

The first of the subjoined figures is a representation of the phenomena observed, as above mentioned, by Sir Henry Englefield. The sun being about 14 degrees above the horizon, portions of two halos were seen, one at 94 degrees, and the other at 88 degrees from it; the interior part is sometimes a pale yellow, and a degree broad; and the other, which was about 14 degree breadth, was tinted with prismatic colours, the red being nearest to the sun. On the left hand side of the interior ring, and in a line imagined to be parallel to the horizon, was a faint parhelion; and vertically above the sun, in the same ring, was a very remarkable parhelion rather brighter than the true sun: it had a pearly appearance, was ill defined, and about 1° diameter. From the parhelion proceeded a bright curve of contrary figure, being first convex and then concave towards the sun. It extended nearly to the outer circle, and its lower side was tolerably defined, but the upper side was more obscure. In the sky: the parhelion with its curved prolongations is said to have had very much the appearance of a vast bird hovering over the sun.

The second figure is a representation of a great double halo which was observed by Captain Parry: in this, a horizontal circle of light, at the intersections of which with the interior halo were parhelia, passed through the true sun; and there were several other figures, such as is be is the case in the two halos and at the lower extremities of the outer one, the latter being incomplete. The altitude of the true sun was about 23 degrees; and the radii of the two circles were, respectively, 223 degrees and 48 degrees. The lowest parhelion was very bright, but had no colours, while all the segments were strongly tinted with colour. Above the sun, at about 26 degrees from it, and between the two halos, was a small spot of a third halo, which appeared to be elliptical, and the space between the two segments was extremely brilliant, in consequence of strong refractions of the sun's rays from the snow which floated in the atmosphere.

In the regions, the sky was often of a peculiar frequent and brilliant: and, near the equator, Humboldt has observed small ones surrounding the planet Venus.

The foregoing, which has been observed by the halo by Mariotte and Dr. Young, is nearly as follows:—Between the spectator and the sun immemorial crystals of snow or ice, having the form of equilateral prisms, may exist in the air, in all possible positions; of these probably one half will be so situated as to be incapable of transmitting any refracted light to the eye, but vast numbers may have their transverse sections in planes nearly passing through the sun and spectator; and it will follow (the index of refraction in ice being about 1.31 and assuming the angles of incidence to be such that the incident and emergent rays may make equal angles with the surface) that the deviation of the refracted from the incident ray, at the eye of the observer, is about twenty-two degrees. Hence, the incident rays being considered as parallel to one another, there must appear to be formed a circle of light about the sun at a distance from the latter equal to that number of degrees. The semidiagonal of the common halo is rather greater than this quantity; but the index of refraction in ice or snow is uncertain, and the angles of the prisms may, from partial meltling, be rather greater than sixty degrees.

Dr. Young supposes that the rays refracted from prisms so situated may fall on other prisms similarly situated, and may thus suffer two additional refractions at their surfaces; by which means the rays entering the eye of a spectator would form angles of twice the above quantity, or nearly forty-four degrees with the direct rays from the sun; and this may account for the exterior halo. Mr. Cavendish, however, suggested that the latter may be produced by the two refractions which a ray would undergo in passing through face and end of a prism; that is, through two surfaces which are at right angles to one another. Such refractions would cause the incident and emergent rays to make with one another an angle of about 45° 44',; and this is, nearly, the distance of the exterior halo from the sun. The red rays of light, being those which suffer the least refraction, come to the eye from the interior edges of the rings; and hence those edges generally appear of a red colour: the exterior parts should be blue, and they frequently are so; but it may be readily imagined that, with such prisms, considerable irregularities in the order of the colours must take place.

Immediately below of very short prisms, or thin triangular plates, of ice will assume, in the air, vertical positions by the action of gravity; and Dr. Young conceives that horizontal rays from the sun falling on their flat surfaces may be reflected from them to the eye of the observer, so as to produce the appearance of the horizontal circle, or band, of light which so frequently accompanies the halo. Plates of ice disposed so as to reflect the sun's light in a vertical plane may be the causes of the outermost circle to form a vertical diameter of a halo; and a similar explanation may be given of the bands forming oblique diameters such as, on one occasion, were observed by Captain Parry, when the halo had the appearance of a great wheel in the heavens, the sun being
HAM 11

centre. The blending of the reflected rays above mentioned with the horizontal and vertical bands of light intersect the hall, is, apparently, the cause of the parhelia which are very generally observed in those parts of the hall; and, while we are thus favorably situated for observing a second view from a plane passing through the observer, towards the right or left, the axe being horizontal, there will be produced a curvilinear band of light, like a wing, inclining upwards on each side of the second figure, which is probably of the same kind as the dark one observed by Biot. A cloudy day, pretend that the edifice is not so noisy, and that the horizontal and vertical bands of light are not so visible, and that the refraction is not so apparent—A cloudy day, pretend that the edifice is not so noisy, and that the horizontal and vertical bands of light are not so visible, and that the refraction is not so apparent—

HALO/NIA, a genus of fossil plants, allied to Lepidocar-

HAR

Every facility is afforded for students desirous of copying in the gallery, but permission must be obtained from the Chief Commissioner of her Majesty's Woods and Forests, or of the Deputy Surveyor; for without permission no person is allowed to make even the slightest sketch in a picture-book, and he who is guilty in any manner of injuring a picture risks an injury and extremely absurd regulation; for if an artist should wish to sketch a Tudor ruff, or a Stewart tie, or any thing else of so much importance, he must first forward a petition to her Majesty's Chief Commissioner of Woods and Forests.

Hampton Court is a very favourite resort in the summer; there have frequently been as many as 3000 visitors in a single day. There are two catalogue offices where, for a small fee, you can have a copy of any catalogue, and there are catalogues also in Mrs. Janesson's 'Hand-book to the Public Galleries of Art in and about London,' and in 'The Environs of London,' by John Fisher Murray.

The private Dining-room, 668-690. In this room is a richly-coloured portrait of Fisher the composer, by Gaunbourgh.

20. The Cartoon Gallery, 769-775. This gallery is occupied entirely by the seven cartoons of Raphael (Carrossa, F. C. B.), for which it was expressly built by Sir Christopher Wren, and perhaps there never was a building so ill adapted to its purpose. It is now too narrow, the cartoons are placed much too high, and the light is what is to be desired; but it is at the same time a fine collection of excellent pictures, and dirty.

27. The Anti-room, 778-797. In this room is an admirable drawing in pastel of Raphael's, the one of the Triumph of Caesar, which is in the original in the Vatican at Rome; it was drawn by Giambatita Canova for Lord Balfour, who presented it to George III.; this drawing and the cartoons together show Raphael to advantage in this manner of art. This apartment, though styled the portrait gallery, is chiefly occupied by the nine large distemper paintings of the Triumph of Julius Caesar, painted on canvas by Mantegna for the Marchese Ludovico Gonzagas of Mantua, about 1490, after Mantegna's return from Rome; there are some well-known woodcuts of them by Andrea Andreani. These works are Mantegna's masterpieces, and are among the greatest works of the fifteenth century. As naturalist, however, in a very bad condition, and what is still more to be regretted, William I. had them restored by Laguerre in 1690: they were purchased by Charles I., with the collection of the Duke of Mantua, for about 20,000l., and were sold at the state sale for 1000l., while the cartoons of Raphael were sold for 300l. only. In this room is also a portrait of William of Nassau, Prince of Orange; Dobson and his wife, by Dobson; and a picture of the dwarf Sir Jeffrey Hudson, by Mytens.

29. The Queen's Guard Chamber, 857-928. This room contains several portraits of painters; Henry IV. and Mary do Medici, by Poussin; an excellent copy by Roncalli of Guido's triumph of Boniface VIII.; a excellent copy to Van Dyck, which is a copy of the original picture at Munich. 30. The Anti-room, and, 31, the Queen's Presence Chamber, 925-1025, are devoted to naval battles, maritime views, and shipping generally. 32. The Princess Diana's apartments, consist of many beautifully painted halls of ships of war, by Marshall, and three large pictures of the Battle of Trafalgar by Hugghins.

The great hall is decorated with tapestries of the story of Abraham, said to be made from designs by Bernard van Orlay, a Fleming who studied under Raphael at Rome. They are certainly of the style of the sixteenth century, but are charged in manner; many of the heads, however, are full of character, and the composition is in many parts natural and effective. The colours are much faded, but as tapestries they are of a very superior class: Evelyn says of them in his Diary—'I believe them to have been of the kind than the stories of Abraham and Tobias.' They were estimated in the parliamentary inventory at 8000l.; but they were reserved by Cromwell for the state; the whole history is told in ten compartments, beginning with the story of Abraham and ending with the Battle of Marston Moor, where the English are defeated by the Scots. 33. The public dining-room (14), where there is also a tapestry of Tobias, with the angel, taking leave of his father Tobit, and his mother grieving for his departure. In the large apartment of the gallery, called the great hall, are some of the most splendid and beautiful tapestries, in a superb style of composition; their subjects are allegorical, but the colours are so faded that they are almost obliterated. Above the tapestries are portraits of many celebrated persons of the sixteenth century; they are the cartoons of some frescoes painted by him in the ducal palace at Parma.
having been frivolous in character and prodigal in his habits; he was, however, little more than a youth when he died. As a painter he is considered to have been the foremost of his time. He was the most promising of our painters.'

(Adam Smith, "Wealth of Nations," 1776)

HARRISON, a genus of fossil Crustacea (Trilobites), from the Devonian strata.

HARRIS, [Malmesbury, Earl of, P. C. S.]

HARRISON, Chester, although he was not a native of that city, for he was born at Wakefield in Yorkshire, in 1744. While yet little more than a mere lad he was sent to Italy, then considered almost the only effective school for natural study; and during his stay at Rome, where he remained for several years, he made designs for improving and embellishing the Piazza del Popolo, which obtained for him both a gold and silver medal from Pope Pamphilus; and he was also complimented by being elected a member of the Academy of St. Luke. On his return, one of his first works was a bridge of five arches over the Lame, at Lancaster, at which place he was subsequently employed upon various alterations and improvements in the castle. At Chester, he erected the gool, and the comity courts, which last was considered at the time a very fine and correct specimen of the Grecian Doric style, and the portico central, of which he was himself the originator, though the columns, for though only hexastyle, it has twelve columns, there being a second row of six columns behind those in front. He executed several works at both Liverpool and Manchester, in which account, which was published in 1699, and 1687, in the Tower of St. Nicholas' church; in the latter, the Exchange buildings (since greatly enlarged and altered), the theatre (burnt down in 1648, and now succeeded by the new structure by Mr. Inigo Jones and others, in 1673), and the library and reading-room called the portico. The Hill column at Shrewsbury, the triumphal arch at Holyhead, and the jubilee tower erected on Moel Famau in commemoration of the fiftieth year of the reign of George III., are all by Harrison. He also built for the Earl of Elgin his new mansion of Broome Hall, in Scotland, in the Grecian Doric style, which seems to have been equally the favourite one of his noble employer and himself. Cumberland in his "Observer" has complimented Harrison in very high terms for the pure classicism of his taste.

Harrison died at Chester, March 29, 1799.

HARRISON, WILLIAM HENRY, late President of the United States, was born in Virginia, 5th February, 1773. His father was Benjamin Harrison, who was a member of the first United States Congress that sat at Philadelphia, and who was one of those who signed the Declaration of Independence, and was afterwards governor of Virginia, his native state. He died in 1791. William Henry was educated at Hampden Sydney College, in Virginia, before he was 13 years old, but spent the first six years of his life spent in military service. In 1781 he received a commission as ensign in the United States artillery; he was soon after raised to the rank of lieutenant, and in that capacity he was present and distinguished himself at what is called the battle of the Miami, in which a signal victory was obtained by the Indians. After this he was placed in command of Fort Washington, one of the most important defences of the western frontier. In 1791, this war having been brought to an end, he resigned his commission, and was appointed by the Senate in charge of the government of the north-western territory, then comprehending all the country to the north-west of the river Ohio. In 1796, when Indiana was erected into a territorial government, Harrison was appointed to that office, and, continuing it to a legislative body composed of representatives chosen by the people, he was elected a member of the territorial congress. In 1801, when Indiana was erected into a territorial government, Harrison was appointed to the office of governor of the north-western territory, comprehending all the country to the north-west of the river Ohio. In 1799, when the north-western territory was admitted to the state of Ohio, which, by an agreement of the old government of the United States, was held until the creation of Indiana to a state in 1816. He greatly distinguished himself both in the war with the Indians under the conduct of General Lincoln, and in the treaty with the English in 1812 and 1813. In both these events he held the rank of a general. In 1816 he was returned to the House of Representatives as one of the members for Ohio. In 1828 he was sent as minister from the United States to Columbia. By all his services was returned the thanks of Congress. On the 4th of March, 1840, he was elected president of the United States, and to that office he was re-elected in 1844. In 1848 he was re-elected to the presidency, and in 1852 he was defeated by Polk, but in 1860 he succeeded to the presidency, having already been twice elected to it. He died at Cincinnati on January 11, 1861, being the first president who died in office. Harrison was a valiant public servant and an able man; but he did not belong to the circle of friends with his predecessors Washington, Adams, Jefferson, and Madison. In his "Essay on the Aboriginals of the Ohio valley," which was published in "The Transactions of the Historical and Philosophical Society of Ohio," vol. i. 1839, he has made some interesting remarks on ancient Indian mounds and on the original state of the forests of America. (See Lyell's "principal work." "The Strata of England and Wales," vol. iv., p. 177.)

HARTSOEKER, SPIRIT OF. [AMMORIA, P. C. S.]

HARTSOEKER, NICOLAAS, a Dutch natural philosopher, was born at Gouda in 1666; his father, who was a minister of the Reformed religion, intended that he should enter the church as a profession; but a taste for the sciences, which the youth early evinced, prevented this intention from being carried into effect.

From the money which was allowed him by his father, young Hartsoeker saved enough to pay the fees of a teacher of mathematics; and he passed the greater part of each night in studying the subjects connected with the instruction which he received by day.

An accidental circumstance is said to have directed his attention to the construction of optical instruments: having interpreted a flint tube as possibly doing service for a telescope, he was surprised to observe that the extremity, when melted, assumed a spherical form; and he immediately conceived the idea of using such spheres as object-glasses for microscopes. In an essay which he afterwards published he described the form of the object-glass in detail, and, verifying that the discovered the animals which exist in animal fluids (Lekuinsoeker, P. C.); and, with the like instruments, Latorre is said to have, first, perceived the red globules in blood.

In 1674 Hartsoeker was sent to pursue his theological studies at Leyden; and, in that city, he became known to Huygens, who encouraged him in the investigation of his microscopical observations: the two philosophers subsequently went together to Paris, where Hartsoeker was introduced to Cassini, who recommended him to exercise his ingenuity in the formation of object-glasses for telescopes; and it appears that, after several fruitful essays, he succeeded in obtaining some who were superior to any that had been before executed. These were of about 600 feet focal length; and in order that they might have truly spherical forms, he first, by means of sand, made a very shallow excavation in a plate of glass; then giving, by the like means, a slight convexity to one side of the plate of the intended object-glass to be formed, he fixed it in a frame so constructed that by varying the convexity of the other, and, by friction, brought the continuous surfaces of both plates to equal and consequently spherical figures. In 1694 he published his "Essai de Dioptrique;" and in 1686, in "Les Annales du Cabinet Royal," he attempted to give a general theory of the laws of nature respecting the hardness, elasticity, transparency, &c. of bodies. These subjects he afterwards, explained in detail in his "Principes de Physique," which he published in 1700.

The work was criticized by a writer in the "Journal des Savans," in the same year; and Hartsoeker seems to have revenged himself by making a violent attack on the "Mémoires de l'Académie des Sciences." The attack, however, remained unnoticed. It appears to have been the character of Hartsoeker to seek occasions of entering into discussions with his friends; and he, at length, lost the good opinion of the nation by urging captious objections to the results of some of his experiments.

Having become embittered in his circumstances, Hartsoeker was obliged, in 1696, to quit Paris: he retired to Rotterdam, where he published the work above mentioned; and he afterwards removed to Amsterdam. At this time he was introduced to the Czar Peter, then travelling incognito, and he was appointed to give the monarch an account of the book. In his conversation he so agreedable to the Czar that the latter invited him to Russia. Hartsoeker however declined leaving Amsterdam, and the magnates of the city built for him an observatory in one of the last houses.

The Elector Palatine having repeatedly offered Hartsoeker the place of professor of mathematics and philosophies at Düsseldorf, he at length accepted it; and, in the year 1704, he went to reside in that city: he made several journeys to different parts of Germany in
order to visit the learned men of the country; and at Han-over he was presented to the elector by the celebrated Leib-nitz, on whose account Heautot had journeyed. Several letters similar to those of Leibnitz were written, and passed between Heautot and the one of these letters was sent to Heautot in 1719. He had been a resident of the English Academy of Sciences in Paris in 1699; and he was also a member of the Academy of Berlin.

Heautot's life was one of turbulent, at one time, an opinion that there existed in every animal a plastic soul which was charged with the preservation and development of the individual; he is said to have maintained also, and this in the presence of the French Academy, that the idea of a form was imparted to Plato in the Timaeus, that, from the divinity descended a succession of intelligent beings, the lower orders of which directed and preserved the universe; he had moreover seen wild notions respecting an empire which he imagined to exist in the interior of the moon.

In 1722 Hasselequist published a work entitled 'Receuil de diverses Piece de Physique,' on the fait principalement vrai l'invalidité du Système de Newton;' he also caused a letter to be printed in the 'Journal des Savants,' containing some absurd remarks on the hypothesis of the English philosopher. He treated Leibnitz no better, attacking with great violence his philosophy, and that of a good many other philosophers. He would never admit the advantages of the 'Infiniment Calculus,' and persisted in considering it as an unintelligible jargon by the aid of which certain learned men sought to entrances the human universe. He placed the hypothesis of Bernoulli as a superficial and an arrogant man; but his violence is supposed to be less owing to envy than to a worldly taste for distinction.

HARTZ. [Germ. F. C., p. 186.]HASSELQUISTIA, a genus of plants named by Linnaeus in honour of Fred. Hasselequist, M.D., his pupil, who travelled in the Holy Land. It belongs to the natural order Umbelliferae, and is placed by Torrey among the species of Techosum that resemble those of Tordylium, and are regarded by some botanists as monstrous forms of this genus.

HAUGHTON, WILLIAM, a dramatic writer, was probably somewhat the jester of Shakespeare. In Henley's Diary, under the date of November, 1607, he is called 'Young Haughton;' and his name occurs frequently in that curious record, till the end of the year 1608; but not later. In March, 1609, Henley lent him ten shillings to pay a debt, for which he then lay in the Clink prison; and constant advances of small sums, in earnest of the price of dramas which he was writing for the old manager, show him to have been not only a poor, but an industrious fellow-playwright. He wrote several plays unassisted; in others his coadjutors were Chettle, Day, and still more frequently Dekker, with whom he appears to have stood on particularly cordial relations. In 1606 there was a license of a tragedy by his, not preserved, called 'Ferrez and Porrez;' and Mr. Collier has conjectured that Haughton's 'Devil and his Dam,' described as a tragedy about the same time, may have been an alter of 'Grum, the Collier of Crydon.' The same critic is more confident in believing that 'The Spanish Moor's Tragedy,' for which, in February, 1608, Henley made to Dekker, Haughton, and Day a payment of three pounds to account, was the wild tragedy called 'Lust's Dominick,' which was printed for the first time in 1657, and has been inserted (without reason) in the recent edition of Marlowe's works. But the only extant plays in which Haughton was certainly concerned are two. 1. He was sole author of the lively comedy called 'Engelsman for Money;' or, a Woman will have her Will, which (under the latter title) appears in the Quarto of 1601. It was printed in 1610, 1626, and 1631, and has been reprinted in a small collection called 'The Old English Drama,' 1880, 4 vols. 12mo. 2. Dekker, Haughton, and Chettle were jointly the authors of 'The Prince of Pleasure,' acted at the Theatre Royal in St. Martin's Lane in March, 1600, printed in 1603, and reprinted from a very rare copy by the Shakespeare Society in 1841.

HEAUTOT, JEAN DE, a French mechanician, was born in 1676; and in 1692 he caused three burning lenses similar to those of Tschirnhausen to be executed. On the death of the Elector Palatine, Hatzschocker, declining the solicitation of the Landgrave of Hesse-Cassel that he would retire to Unterhosenberg, he died in 1725. He had been a foreign associate of the Académie des Sciences of Paris in 1699; and he was also a member of the Academy of Berlin.

The Abbé Hautefeuille, such was his designation, devoted himself to the study of subjects connected with physical science, and to the construction or improvement of instruments; but he is distinguished chiefly by the claims which he advanced in the year 1722, on the honour of having invented a spring balance for watches. This contrivance consisted of a straight spring of steel which he applied so that it served to regulate the movements. About the same time Huygens invented, for the like purpose, a balance in the same form; it happened however that Hautefeuille had communicated his invention to the Académie des Sciences of Paris in the preceding year; therefore when Huygens applied to the French Government to be allowed the exclusive privilege of using it, he was opposed by Hautefeuille, and he subsequently withdrew his application. It is remarkable that Dr. Hooge had, about the year 1658, invented a balance-spring for watchwes, but he spent several years in improving his escapement, and his watches were not made public till about the same year that the inventions of Huygens and Hautefeuille were in use in Paris.

The other applications of the projects, of Hautefeuille are numerous, but few of them appear to have been brought to perfection. He published in 1692, at Paris, a work entitled 'Receuil des Ouvrages de M. de Hautefeuille,' which is a large volume of engravings; one account of a pendulum clock in which the weight was to be raised by the action of the atmosphere; a method of raising water by means of fired gunpowder; and an account of some improvements in sundials in which the field of view was to be increased by means of a concave mirror; also some observations on machines for raising water; a description of a pump which was to act without friction; and an account of a contrivance for mounting telescopes of great length.

Hautefeuille published a method of finding the declination of a magnetic needle (1658); an account of a magnetic balance (1702); with accounts of a micrometrical microscope, and of an instrument for observing the altitudes of celestial bodies. He also published, in 1719, a work entitled 'Nouveau Système du Flux et Reflux de la Mer,' in which the phenomena of the tides are made to depend upon a particular motion which he ascribes to the earth; but the best of his works is his ' Dissertation sur la Causa de l'Echo,' which had been read before the Academy of Bordeaux in 1718, and was published in that year in 1724.

Hautefeuille appears to have been in haste to publish his ideas as soon as they arose in his mind, without waiting to consult with others; and sometimes he forced them to the text of experiments; as it appears from some of his projected schemes of observation which have not led to any object of practical utility. The opinion entertained of him by his countrymen is manifest from the fact that he was never admitted to the company which he maintained to the Sciences though he ardently desired that honour. He died October 18th, 1755, being then seventy-seven years of age.

(Histoire Universelle.)HAWEER, [PEDIAS, P. C.]HAYMAN, FRANCIS, R. A., the best historical painter in England before the arrival of Cipriani, was born at Exeter about the commencement of the eighteenth century. He was the scholar of Robert Brown, and was in early life much employed by Fleetwood, the proprietor of Drury Lane old theatre, and by Tiers, the proprietor of Vauxhall. He also made many designs for bookshellers, the best of which are those for the Pictures of the Life and Writings of Shakespeare. He was the first librarian to the Royal Academy; he died in 1776. (Edwards, Anecdotes of Painters, &c.; Somerset House Gazette, 1824.)HEALTH, PUBLIC. [CONFORTABLE, P. C.]HEALTH, PUBLIC. [Public Health, P. C. S.]HEARSAY. [EVIDENCE, P. C.]HEAT. [ABSTRACTION AND ABSORPTION OF HEAT, P. C. S.; Climatic, P. C.]HEAT, ANIMAL. The conversion of the food of man and the higher animals into animal heat the body is attended with changes which produce an emission of heat which constantly continues to change the temperature of a body, and which is not entirely at the disposal of the animals. The temperature of the
medium in which it exists. The degree of heat possessed by animals not gifted with the power of locomotion is very small above that of surrounding media, and in this respect resembles the heat given off by plants. (TEMPERATURE OF PLANTS, P. C.) In proportion as animals possess the power of locomotion they evolve heat from their bodies. This arises from the fact that the heat system most exercised there is greatest demand made upon the nutritious processes going on in the system. We should therefore expect to find that the quantity of heat developed in the invertebrate animals was less than that in the vertebrate class. Infusoria are in a time capable of resisting cold; for when the water in which they are contained is frozen, the animalcule is observed to live for a time in a little uncoagulated space which is transparent from its body not resisting. John Hunter found that various forms of Annellida, as leeches and worms, and several of the Mollusces, exhibited temperatures higher than the surrounding media. As might have been anticipated from their activity, the insects of all the invertebrate animals exhibit the highest temperature. They have been lately the subject of experiment by Mr. Newport. He found that they possessed a temperature above that of the medium in which they lived, varying from 2° to 9°. With respect to the temperature of the different tribes, Mr. Newport observes, 'Our previous observations lead us to anticipate the higher temperature in those insects, in their perfect state, have the highest temperature, while, on pursuing the inquiry, it is found that those species which have the lowest temperature are located on the earth. Among the volant insects, those by far the highest are those of the highest temperature which pass nearly the whole of their active condition on the wing in the open atmosphere, either busily engaged in the face of day despolling the blossoms of their host, or flying wanton from flower to flower, and breathing the largest amount of atmospheric influence. Of these the hive-bee, with its long train of near and distant affinities, and the elegant and sportive butterflies, have the highest. Next to these are placed the volant enemies of the bees, the hornets and wasps, and others of the same order; and, lastly, a tribe of insects which have always attracted attention, and in general are located on the ground, but sometimes enjoy the voluntary condition—the ants, the temperature of whose dwelling has been found to be considerably above that of the atmosphere. Next below the diurnal insects are the crepuscular, the highest of which are the sphinges and moths; and almost equal with them are the Melolontha. In insects which live in societies the temperature is still greater. Mr. Newport found that a bee's nest in a chalk bank had a temperature 14° to 16° above that of the atmosphere, and 17° to 19° above that of the soil. Amongst the vertebrate animals, fishes and reptiles have the lowest temperature. Dr. Davy, John Hunter, and others, have found that fishes have a temperature of from 7° to 9° above the surrounding medium.

In man the temperature of the accessible parts of the body, as the mouth, axilla, &c., is usually between 97° and 98°. The heat of a blood in summer is from 96° to 98°, while in winter it varies from 100° to 101°; in disease it rises to 105° or 106°. In healthy persons the temperature is said to attain its maximum during the day, and to fall from 1°8 to 2°7 during sleep. Dr. Davy has also found that the temperature of the interior of the body is 2°7 to 3°6 higher than in temperate climates. Most of the Mammla have a higher temperature than man, and birds develop a greater quantity of heat than any other class of animals. This arises from the nutritional changes going on in the bird in order to support the enormous muscular power which it is compelled to exert during flight. The following is a table of temperatures, as given by Rudolph and Tieffenberg, for several birds and Mammalia.

There is now no question that the cause of animal heat is the chemical changes which are going on in the nutrient fluid of the body. During the act of respiration a large quantity of oxygen gas is taken into the lungs, which is absorbed by the blood. In this fluid it meets the various compounds of carbon which have been taken in with the food; and the consequence is a union of the oxygen with the carbon, and the formation of carbonic acid gas, which is given out when the blood again reaches the lungs during expiration. When carbon and oxygen unite out of the body, heat is the result, and the same thing occurs when they unite in the body; and it is this peculiar property of the bodies of animals that the bodies of animals are raised to a given temperature by the circulation of the blood through the system. It has been calculated that there is more oxygen absorbed than is given out of the system; and this is the cause of the heat; it is probable that this enters into combination with hydrogen and compounds of hydrogen, nitrogen, and carbon, and thus contributes to the raising of the animal heat.

This theory of animal heat explains many well-known phenomena; for instance, the slight independent warmth of the foetus, and of those young animals which are born in an imperfectly developed condition. The low temperature of persons with scarce coverings, where the blood is only imperfectly oxygenated, and the cold experienced by aged and debilitated persons in whom a small quantity of blood circulates slowly; and also the increased temperature observed in persons labouring under attacks of inflammatory disease where the blood circulates rapidly, are also confirmatory facts. The phenomenon also exhibited by the hibernation of animals are explained by this theory. During the period of hibernation, when the blood is circulating slowly and respiration is almost suspended, and the oxygenation of the blood is feebly performed, the temperature of the animal is low. The observations ofopal and others show that hibernation is prevented by a temperature of from 95° to 90°, whilst it is induced in those animals which exhibit it even in summer by the application of artificial cold.

The production of heat is also dependent on the mass of the globules of the blood and the regularity with which they circulate. When there are few blood-globules the necessity for the absorption of oxygen is diminished in the same ratio, and the circulatory system alone causes the consequence that there is less heat developed. On the other hand, blood containing an excess of globules, but which is circulated less slowly, develops less heat than blood which contains a smaller proportion of globules but which is more rapidly circulated, for more oxygen may be consumed in the latter than in the former case.

The metamorphosis of the blood and the general changes of matter lead to still another auxiliary source of heat. It has been shown by Pouillet that all solid bodies, organic and inorganic, undergo an elevation of temperature when moistened with different fluids. In organic substances it may amount to from 11° to 18°. Since the act of metamorphosis is always effected through humid membranes, this source of heat must be regarded as of great importance, even if it be not actually identical with the catalytic metamorphosis of the cells themselves. (Sim.)

HEBER, REGINALD, second Bishop of Carlisle, was born April 21, 1788, at Hespe, Cheshire, of which place his father was for many years co-rector. The family was of considerable antiquity in the county of York, and on the death of an elder brother without heirs-male, the father of Reginald Heber succeeded him as rector of Holy Trinity, Marton, Yorkshire, and patron of the rectories there, and to estates at Hodnet, Shropshire, which had come into the
Http

At a very early period of his childhood Reginald Heber was remarkable for his piety and for his eager thirst for knowledge. An excellent memory enabled him to recollect through life whatever he read with almost verbal accuracy. He was early versed in the Scriptures, and at seven years old he had translated Phaedrus into English verse. At eight he was sent to the grammar-school of Hawkhurst under Dr. Kent, and in his thirteenth year he was placed in the school for clergymen near Lichfield. He remained there about three years, and in November, 1800, was entered at Brasenose College, Oxford. In his first year at the University he gained the prize for Latin verse, the subject of his poem being on the commencement of the new century. In the spring of 1803 he wrote his prize poem, 'Palestine,' which has obtained a permanent place in English literature. His career at Oxford was not of a very singular character; the amiability of his manners, his gentleness of disposition, and the charm of his conversation, his society was courted by persons of all ages. In his studies he evinced no taste for the exact sciences, but a fondness for language and literary views than is usual with most young men at the universities. In 1804 he became a Fellow of All Souls. The year after he had taken his degree he gained the Bachelors' prize at Oxford, in this branch of literature.

About the middle of 1805, in company with his friend Mr. John Thornton, son of the member for Surrey, he set out on a continental tour. They proceeded through Russia, Poland, Hungary, Austria, and the Crimea, and returned to England in October, 1806. In 1807, before he had obtained his degree of M.A., he took orders, and was instituted by his brother Richard to the family living at Heber's Hill. His history at this time is a 'depressing way situation between a parson and a squire.' Never however were the duties of a parochial clergyman discharged with more exemplary zeal and benevolence; and Heber's conduct in his parish has often been pointed at as displaying in the greatest perfection all the best characteristics of a Church of England priest. In April, 1809, he married Amelia, youngest daughter of Dr. Shipley, Dean of St. Asaph. While discharging the duties of his parish with so much earnestness he was ardently attached to the pursuits of literature. He was a frequent contributor to the 'Quarterly Review' from its commencement. In 1812 he commenced the preparation of a concordance to the history of the Bible, and the laborious work, which he labored with much delight, but other duties compelled him to suspend this work, and no part of it was ever published. In the same year he published a small volume of 'Poems and Translations,' which was reviewed in the 'Church Observer.' 'The Hymns,' with a view of improving the psalmody and devotional poetry used in churches, was also a favourite recreation. He was an elegant versifier, and continued to indulge his poetical talents even while engaged in visiting his diocese in India. He had a great disgust for controversial theology, and only once was engaged in a discussion of this kind, in reply to what he conceived were the unwarrantable impugnations of a writer in the 'British Critic.' His life was diversified by an occasional visit to his friends in other parts of England, or to his father-in-law in Wales, and by correspondence with a few friends. His political views were those of the High Church and Tory party, but devoid of all intolerance. He was well content with things as they were, and apparently had no perception of those abuses which have been swept away within the last thirty years. In 1815 he was appointed Lapponian lecturer, and the subject he selected was 'The Personality and Office of the Christian Comforter.' In 1817, Dr. Luzmore, the Bishop of St. Asaph, appointed Heber to a stall in that cathedral. He now left his father-in-law, the Dean. In 1819 he edited the 'Tracts for the Times.' The other works consist of 'Parish Sermons' preached at Hodnet; and Sermons preached in India. In April, 1822, he was elected a member of Lincoln's Inn, for which he had formerly been an unsuccessful candidate. The 'Parish Sermons' and 'Tracts for the Times' were reprinted in book form.

Heber was remarkable for his piety and eager thirst for knowledge. His memory was excellent, enabling him to recollect through life whatever he read. He was early versed in the Scriptures and had translated Phaedrus into English verse at eight years old. In 1803, he gained the prize for Latin verse at Oxford. He went on a continental tour with his friend Mr. John Thornton in 1805. In 1807, he took orders and was instituted as a parson in the family living at Heber's Hill. He conducted his parish with zeal and benevolence. He was a frequent contributor to the 'Quarterly Review' and published a volume of 'Poems and Translations' in 1812. He also wrote 'The Hymns' and 'Parish Sermons' as well as 'Tracts for the Times.' He was appointed Lapponian lecturer in 1815 and later became a member of Lincoln's Inn in 1822.
HECTOR ('Euryp'), the greatest of the Trojans heroes who figure in our accounts of the Trojan war. He was the son of Priam and Hecuba, and married to Andromache. The poet of the Iliad personifies him as the very type of a bold and gallant warrior, whose martial spirit likewise to his heart, but as a hero ennobled by all the more tender and humane virtues, so that it almost seems as if the poet had developed his character more with real motives of human life than with any. Hector is the favourite of his parents, and himself a happy husband and father. The reader need only be reminded of the beautiful passages in the 'Iliad' (vi. 300 sq.), where Hector, about to battle, takes leave of his wife and child, and where (xiv. 3), amid the lamentations of his parents, he prepares himself for the contest with Achilles. Wherever the battle is fiercest, Hector is foremost, and, protected by his father, As (Max) and Apollo, he fights most vigorously against the bravest of the Greeks, such as Ajax, Nestor, Diomedes, and Teneus. He was foremost among those who stormed the Greek camp, and advanced as far as the place where their ships were stationed. Patroclus then came forward and drove the Trojans back to their city, but was slain by Hector. This calamity for Achilles from his inactivity, and, thirsting to avenge the death of his friend, he sought Hector, who, though inspired by his parents to save himself, resolved to engage with his enemy. Achilles thence chased him round the walls of Troy, and finally pierced him with his spear. Hector bore his arrows with his^ and dragging his corpse clung and dragged along the camp of the Greeks; at the funeral solemnities of Patroclus, it was dragged thrice around his tomb, and then thrown away to be devoured by the dog; but Achilles, in the contest with a dog, dragged the hero, who, when he appeared as a suppliant before him and begged for it, the remains of Hector were buried at Troy, where funeral sacri- fices were offered to Hector as a hero; at a later time, however, his remains are said to have been conveyed to Thessal., in pursuance of an oracle. (Pausanias, iii. 18. 9; ix. 18. 4.)

HEDJAZ. [Arabia, P. C. and P. C. S.]

HEDYPSARUM (from ἥδυπασα, the Greek name of the Coronilla secundaria), a genus of plants belonging to the na- tural order Leguminosae. It has a 5-5cleft calyx, with the segments linear-subulate and nearly equal; the corolla with a large vexillum, and obliquely truncate; keel much longer than the wings; the stamens didymous; the legume of num- erous flat orbicular or lenticular regular 1-seeded joints, which are connected together in the middle, and therefore the sutures are convex on both sides. The species are herbs or under-shrubs, with unequally pinnate leaves, axillary, with simple peduncles, and browning racemose spikes of large purple, white, or cream-coloured flowers. The old genus Hedypas has been subdivided into many smaller genera, as (beneath) (Genus) and (S) by old writers, who form the genus Onobrychis, which differs from Hedypas in the legumes consisting of many joints, not of one joint, as in this genus. It is a native of Spain and Italy. Hedypas grows wild in great abundance, and horses and mules are fed with it. It grows well in our gardens, but probably would not make a good field crop.

H. fruticosum has an erect shrubby stem, the leaves with 5-7 pairs of alternate elliptic leaves, which are clothed with pubescence on both surfaces; the flowers few, disposed in spikes; the wings hardly longer than the vexillum; the vexillum the length of the keel; the joints of the legume wrinkled; the seeds slightly echinate. It is a native of Siberia in sandy places. It has a pale purple flower, and is a very handsome plant. Horses eat it with avidity, and it may be made useful in fixing sand, in which it grows readily.

H. Macenaei has recumbent stems; the leaflets oblong, clothed on both surfaces with cuneate pilis; the stipules sheathing; the joints of the legume transversely wrinkled and plicate. It is a native of Greece, Abruzzi, and North Italy.

H. lutescens is used in Cochín China as a stomachic, and H. alpinum is used in Siberia for the same purpose. The P. C. S. No. 88.
reason, very considerable. His works are not indeed without the influence of his time, and the demand of our age; but it must not be forgotten that Hegel was the first historian, at least in Germany, who breathed life into the history of antiquity, saw in it something more than a mere succession of facts, and lifted it to a level with the more peaceful pursuits of the antients and their principles of government. In his private life he is said to have been a man of the most gentle and benevolent disposition.

(For further particulars of his life, see the Heerden's Letter to a friend in the first volume of his historical works, and Karl Hocke, A. H. L. Heenan, eine Gekrichtsnrede, Göttingen, 1843, 4to. A complete list of his works may be found in the 'Verzeichnise der Bruchstücken' in the Universitats Göttingen, vol. ii. p. 194; vol. iii. p. 344; and vol. iv. p. 442.)

HEGESIAS (Hegesiás), a Greek rhetorician and historian, was a native of Magnesia, and lived about the time of the historian Timaeus, that is, about 250. Respecting his life no particulars are known, but as an author he appears to have been of some importance in antiquity, though more for his bad than for his good qualities. Strabo (xiv. p. 649) calls him the founder of that florid and inflated style of oratory which was afterwards designated by the name of the Asiatic; and this testimony is borne out by Cicero ('Brev. 68'; 'De orat. iv. 7') and other historians. He is mentioned as one of the Attic orators, especially Lysias. He seems to have been destitute of all the qualities required of an orator, and to have talked more than he wrote. His oratory was never more than expressive of his person. This we must conclude both from the opinions of ancient critics as well as from the few specimens of his oratory which have come down to us, and are preserved in 'Schriften seiner Zeitgenossen,' and in the 'Nekrolog' of 1838.

As an historian he appears not to have been much better than as an orator. The subject which he chose was the history of Alexander the Great, but that he had no notion of the dignity of history is evident from the specimens given by Dionysius, Phorus, and Plutarch ('Acer. 3'); and A. Gellius (ix. 4) does not appear to be much mistaken in classing him among those who, unconcerned about historical truth, filled their books with nothing but stories and incoherent chimeras. (Compare Strabo, ib. p. 396; Longinus, De Sublim.; Theon, Progymnasm.; St. Croix, Examen critique des Historiens d'Alexandre, p. 47, &c.)

From this Hesiodus we must distinguish HEGESIAS the Cyranec philosopher, who lived somewhat earlier, in the reign of Ptolemy Philadelphus, and was a disciple of Parabataes. His doctrines, however, differed in several points from those of other Cyneces, and so much so that his followers were regarded as a distinct school, and are called as such Hegesiac (Hegesiak). In the main points they agreed with Aristippus, the founder of the Cyneces school, who maintained that happiness is in the power of an individual, but Hegesias and his school went further; they denied that kindness, friendship, and benevolence had any independent existence, but that they arise and disappear with the feeling of the individual, and are nothing more than things possible to attain, for our body is subject to many sufferings, and the soul suffers with it. Life and death are equally de- sirable; nothing is by nature either agreeable or disagreeable, but becomes so through the circumstances in which it is made. A wise person therefore looks upon life with indifference, and regards nothing and nobody so much as himself, reducing everything to his own convenience. This miserable view of human life was somewhat softened down and improved by Anniceris, the disciple of Hegesias. Hegesias wrote a work entitled 'Areaprepsev, in which he introduced a person related to Socrates, and explaining to his friends why death was more desirable than life. He seems to have taught philosophy at Alexandria, but as in consequence of his doctrines many persons destroyed themselves, King Ptolemy Philadelphus is said to have forbidden him to teach any more. (Diogenes Laert., ii. 86, 93-96; Cicero, Tusc. i., 84.)

HEINRICH, CARL FRIEDRICH, a distinguished 'german scholar, was born on the 8th of February, 1774, at Münster, in Westphalia, the son of the pastor. He received his first education at the Klosterschule of Dondorf, and afterwards at the Gymnasium of Gotha, where he enjoyed the instruction of Döring, Manno, Jacob, and other pupils of the principal Greek writers, even before he entered the Gymnasium, and his intimate acquaintance with them caused him to be looked upon as a wonder in town. In 1791 he went to Göttingen,
Almost all the species of Helianthemum are elegant plants, of hardy growth, and easily cultivated. They grow best in a light sandy soil, and should be protected during the winter in a frame.

(Don, Gardiner's Dictionary; Bahnhoff, Manual of British Botany; Leuton, Encyclopedia of Trees and Shrubs; HELIOTROPIUM (from ἥλιος, the sun, and πτωτος, a turning), a genus of plants belonging to the natural order Eriocaulaceae. It has a saucer-shaped corolla, with the throat united, but the segments behind the limb furnished with a single fold or a tooth between each; the stigma sub-casual; the carpell 4, 1-celled, combined, closed without any manifest receptacle. The species are annual or shrub plants with alternate leaves and circular spikes of small blue or white flowers.

H. Parviflora, Peruvian Heliotrope or Turnsole, has a shrubby stem, pinnate oblong-linear somewhat toothed leaves, terminal branched spikes; the tube of the corolla hardly the length of the calyx. The mouth of the corolla is intersected with five plumes of a purple-lilac colour with a greenish throat. It is a straggling, growing one or two feet high, and much cultivated on account of the scent of its flowers, which resembles very much the smell of the vanilla. It is a native of Peru.

H. Europaeum, the European Turnsole or Heliotrope, has an herbaceous erect stem, with ovate flatly finely tomentose leaves, the lateral spikes solitary, the terminal ones conjugate, the calyx spreading in the fruit-bearing state. It is a native of Greece and of the islands of the Archipelago. It has large white corollas with a yellow throat. This appears to be the Heliotropium pumilo of Dioscorides (iv. 60), and the H. hypogynum, the Heliotropium pumilo.

Upwards of eighty species of this genus have been enumerated. They are natives of the warmer parts of Europe, Asia, Africa, and America, and are found in New Holland. They do not bear the propertion of flowers.

Many other species besides those here described have sweet-scented flowers, and are cultivated on that account. Some of them are consumed in large quantities by perfumers for the sake of their volatile oil. They are aromatic and also medicinal, and poultices made of the leaves have been applied to cutaneous and scrofulous sores. It is supposed that the plant used for the cure of warts, and called 'Verrucaria,' belonged to this genus. In their cultivation the shrubby and perennial kinds will be found to thrive in any kind of rich light soil, and cuttings will root readily in sand under a glass. The European annual species may be propagated from seeds, and border the borders, while the shrubby and perennial species must be sown upon a hot-bed before being planted out.

(Don, Gardiner's Dictionary; Burnett, Outlines of Botany; John Garbett, Flora Classic.)

SINUS, (HEL. MAXIMILIAN, a distinguished astronomer and member of the order of Jesuits, was born May 16, 1720, at Schönmitz in Hungary, and manifested, at an early age, a decided taste for the study of natural philosophy and astronomy. At twenty-five years of age he was employed as an assistant in an observatory belonging to the Jesuits at Vienna, and he was at the same time keeper of the museum of experimental philosophy which had just then been formed in that city. In 1748 he was made rector of an academy at Leuchtenburg in Hungary; but this post he held only one year, when he returned to Vienna. Here he completed his theological studies, and made a small number of observations, which were afterwards taught in mathematics. He took orders in 1761, and after three years he obtained the rank of doctor, with an appointment to the professorship of mathematics at Claussenburg in Prussia. Remaining continued for several years, he again returned to Vienna, where he was established in an observatory which had been built in conformity to his own directions; and he held the appointment during the remaining period of his life. Besides the various observations, he was charged with that of giving lessons in mechanism; as, in England, about eighty years earlier, the first astronomer royal was required to teach the use of nautical instruments to young boys from Christian schools. But in this situation he was situated for twenty to twenty-five years. A brother of Hell was a distinguished mechanician at Schönmitz, and in the invention of the clock of the sun-clock, which he was engaged in making, he was aided by the young man who is now, by the naked eye, 1775 + 400, and one on a New Theory of the Aurora Borealis, 1776.

All his works were published at Vienna; and he died in that city in 1788, aged sixty-two years. A brother of Hell was a distinguished mechanician at Schönmitz, and in the invention of the sun-clock, which he was engaged in making, he was aided by the young man who is now, by the naked eye, 1775 + 400, and one on a New Theory of the Aurora Borealis, 1776.

The mediation of Count Bechhofer, who was sent from Copenhagen for the purpose of making the proposal, he accepted an invitation from the court of Denmark to undertake a journey to Walhoy in Lapland, in order to observe the transit of Venus over the sun's disc. Accordingly he set out from Copenhagen, and, after spending a short time at Copenhagen, he proceeded to the place of his destination: he was absent about two years and a half on that mission, when, having successfully carried out his object, he returned to Copenhagen; but the proceedings became so public that he took advantage of his residence in Lapland to study the geography, the natural history, and the climate of the country; the history, language, and religion of the people, with the state of the art of agriculture. In the latter he was promoted to the degree of professor of the observatory, and on the phenomena of the tides and winds, and on the variations of the barometric column; and he measured the heights of the principal mountains. After his return he prepared a work containing a full account of his researches, which was to have been published in three volumes, 4to., but it never appeared.

Hell was very fortunate in the sky being favourable, on the day (June 3, 1769) that the transit took place, so that he was enabled to observe the interior contact at the commencement, and both the interior and exterior contacts at the conclusion of the phenomena; and the accuracy of his observations that the value of the sun's parallax, which he deduced by comparing them with the corresponding observations at certain other places, agreed, within one-fifth of a second of arc, with all the best observations which were made.

On accepting the engagement, Hell was enjoined by the Danish ministry to abstain from publishing any account of his observations in any foreign language, until the Danish Astronomer Royal had made all the requisite computations. The delay which, in consequence of this injunction, took place in making Hell's observations public, gave offence to Langand, who had, by letters addressed to the governments of Europe, greatly promoted the measure of observing the phenomenon at different places on the earth's surface; the two astronomers were however soon reconciled, and they continued to correspond with each other on matters relating to the transit, which was read before the Academy of Sciences of Copenhagen, November 24, 1769.

The principal work published by this astronomer was a series of Ephemerides in thirty-five volumes, 4to., the collection being entitled 'Ephemerides Anni 1757—1791 ad Meridianum Vindobonense Calculi definiti.' With the exception of two volumes, these contain appendices on astronomical subjects by himself or other scientific men, chiefly by Pilgram and Trisonneker; the former of whom edited the work during the absence of Hell in Lapland. The rest of his publications on astronomical subjects are as follow:—

Tabularium Astronomicalum Annualum, 1759; Reliquarum Tabellarum, 1763; Tabulae Lunae, 1763; Mayer cum Supplemento, etc., 1763; De Salis, 1765; De Transito Veneris ante 1767, 1765; De Transito Veneris ante 1767, 1769; Watabrii, 1769; De Paralliali Solis, 1769; De Revolutionibus et Transitibus Veneris, anni 1769, 1773; and Methodus Astronomiae sine Ursi Quadrantis, etc., 1775. He also edited a collection, which had been made by Halberstein, of the astronomical observations made by the Jesuits at Pekin from 1717 to 1752; this was published at Vienna in 2 vols. 4to., in 1768.

Besides these works he published 'Elementa Algebrae J. Crivelli,' 8vo., 1745; 'Admonitum Memorae Manuale Chronologico-Geologico-Historicum,' 16mo., 1750; 'Elementa Arithmeticae Numericae et Literales,' 8vo., 1763; also a tract of 'Tabulae Anomaliarum,' which had been seen by the naked eye, 1775, and one on a New Theory of the Aurora Borealis, 1776.

His works were published at Vienna; and he died in that city in 1788, aged sixty-two years. A brother of Hell was a distinguished mechanician at Schönmitz, and in the invention of the sun-clock, which he was engaged in making, he was aided by the young man who is now, by the naked eye, 1775 + 400, and one on a New Theory of the Aurora Borealis, 1776.

All his works were published at Vienna; and he died in that city in 1788, aged sixty-two years. A brother of Hell was a distinguished mechanician at Schönmitz, and in the invention of the sun-clock, which he was engaged in making, he was aided by the young man who is now, by the naked eye, 1775 + 400, and one on a New Theory of the Aurora Borealis, 1776.
HELSTON, a market town and parliamentary and municipal borough, in the hundred of Kerrier or Kierrier, 'in the county of Cornwall, 296 miles west south-west of the General Post Office, London: viz., 197 to Exeter by railway, and from thence 99 miles by coach road through Ockhampton, Launceston, Bodmin, and Truro. Helston was made a borough by King John (A.D. 1201). According to Lysons, the townsmen paid him forty marks of silver and a palfrey that their town might be made a free borough. King Edward I. made it one of the coinage towns; and it sent members to Parliament from his reign. There was a castle here in which Edmund, Earl of Cornwall, cousin of Edward I., resided at one time, but it was afterwards so neglected that it was pulled down in the time of Edward III., and nothing now remains of it. The Saxon name was in the reign of Henry VIII. one of the decayed towns for the repair of which an act of parliament was passed.

The town stands on the eastern bank of a small stream called the Loe, now called the Loe, which flows below the town a wide expanse of water called Loo-pool. The river Hel or Helil, distinguished from another stream of the same name in the county, as the Helil in Kierrier, and sometimes called the Halford, flows about two miles east of the town, or rather less. The streets are irregularly laid out; but are paved and lighted with gas, and the town presents a neat and clean appearance. The market-house and town-hall are near the centre of the town; and the ancient coinage-hall stands at the end of a street to which it gives name. There are no remains of the castle. The Church dedicated to St. Michael is a modern building of 'white moorstone' (granite), erected by the Earl of Godolphin in A.D. 1768.

There are a baptist meeting-house and a Wesleyan chapel.

The population of the old borough and chapelry which has an area of 136 acres was in 1841, 3844; the number of houses was 765, viz., 682 inhabited, 66 uninhabited, and 15 buildings.

The number of houses in 1831 was only 616, viz., 561 inhabited, 23 uninhabited, and 12 buildings; the population was 2693, so that the increase of population in the ten years 1831-41 was 291; and the increase in the number of inhabited houses, 101. The town is the centre of an important agricultural and mining district: it has two markets, on Wednesday and Saturday. When about six miles near the town are five other markets in the year. A great number of shoes are made in the town, and sold at the markets and fairs; or are sent to London, where they are retailed in the two large retail shops. The Act returned two members, now returns only one; the old borough was, for parliamentary purposes, enlarged by the addition of the adjoining chapelry of Sithney and of a considerable part of the parish of Wendron. The population of Sithney parish in 1841 was 3052, of Wendron 6576, which, united with the population of the old borough, makes a total of 12,522; but what deduction is to be made for that part of the parish of Wendron which is now a parliamentary borough we have no means of ascertaining.

The number of electors on the register in 1832-5 was 326, in 1839-40 it was 406, showing an increase in four years of 50 voters. The town is a polling station for the western division of the county of Cornwall. By the Municipal Corporations Reform Act, the borough has 4 aldermen and 12 councillors, but was not to have a commission of the peace except on petition and grant. The old municipal boundaries have not been altered. The living is a perpetual curacy united with the vicarage of Wendron, of which parish the chapelry of Helston is a dependency: the clear yearly value of the united benefices is 872l., with a glebe of 13 acres. The living is in the archdeaconry of Cornwall and the diocese of Exeter. They were in the chapelry of Helston in 1833 two national schools with 100 boys and 70 girls partly supported by subscription; and 20 boys and 20 girls with 40 children of sex not stated, giving a total number of

589 children, or about one in eight of the population (according to the then recent census of 1831) under daily instruction. There were at this time (1832) two Sunday-schools, with 260 children, viz., 127 boys and 133 girls connected with the two dissenting congregations.

(Stonydown, *Manual of British Botany*.)

HELVENNA, [LYSONS], FELICIA DOROTHEA, was born September 25, 1794, in Liskeard, Cornwall, where her father was commercial agent at Liverpool for the Venetian government. Felicia Dorothes Browne was the fourth child of a family of three sons and three daughters. About the year 1800 Mr. Browne, in consequence of the failure of a mercantile concern in which he was engaged, removed his family from Liverpool to an old mansion, spacious and solitary, called Grywych, not far from Abergele, in Denbighshire, North Wales. Mr. Browne died not long afterwards. Felicia Browne began to write poetry before she was nine years of age, and her mother, a woman of education and taste, was her first confidant and encourager.

Miss Browne's first volume of poems was published in 1816, and composed in a few months, viz., when she was between 1803 and 1804. A harsh review of this little volume affected her so much that she was confined to her bed for several days. Her second volume, 'The Domestic Affections,' was published in 1812.

In 1812 Miss Browne became the wife of Captain Hennems, of the fourth regiment. His constitution had suffered so severely in the retreat upon Corunna, and subsequently by fever caught in the disastrous Welcheren expedition, that he felt it necessary, a few years after their marriage, to exchange his native climate for that of Italy. This at least is the motive assigned for his leaving his wife; but, their union, it is said, was not happy, and this separation, which took place just before the birth of her fifth son, closed it for ever.

Mrs. Hennems, with her five sons, went to reside with her mother, then living at Brownwell, near St. Asaph, in North Wales. Mrs. Hennems now resumed her literary and poetical pursuits with increased ardour. She studied the Latin, Italian, Spanish, Portuguese, and German languages. She made some translations from Horace, Herers, and Camoens, and contributed a series of papers on Foreign Literature to the Edinburgh Magazine. 'The Restoration of the Works of Art to Italy' was published in 1815; 'Tales and Historic Scenes,' in 1819; and, about the same time, 'The Sepulchre,' a didactic poem, in heroic rhyme; and 'Modern Greece,' in ten-line stanzas. Her poem of 'Dartmoor' obtained the prize from the Royal Society of Literature in 1821.

In 1827 Miss Browne became acquainted with the Rev. Reginald Heber, afterwards Bishop of Calcutta, who passed a part of every year at Bodrhyddan, near St. Asaph, and their acquaintance soon ripened into friendship. At his suggestion she undertook the literary work, the tragedy of 'The Vespers of Palermo,' which was represented at Covent Garden Theatre, London, in 1828. It was unsuccessful there, but was afterwards better received at Edington, when Walter Scott wrote an epitraphe for it. 'The Siege of Valencia, the Last Constantine, and other Poems' was published in 1828.

In 1835 Mrs. Hennems was divorced, with her mother, her sister, and her own sons, to Rhyllon, near St. Asaph. Her sister had returned, in 1821, from Germany, where one of her brothers was attached to the Vienna embassy, bringing with her a fresh supply of German books, and Mrs. Hennems's delight in German literature may be dated from that time. Her 'Lays of many Lands,' most of which appeared in the 'New Monthly Magazine,' then edited by Thomas Campbell, were suggested by Heber's 'Stimmen der Gegenwart,' Hone, M.R.C.S., prefixed by 'The Forest Sanctuary,' formed her next volume, published in 1827, which was followed, in 1828, by the 'Records of Woman.' Most of these poems were written at Rhyllon, and many are from facts which the melancholy occasioned by the recent death of her mother, for whom her affection was always exceedingly strong.

In the autumn of 1828, on the marriage of her sister, and the removal of her family, Mrs. Hennems was left alone, Mrs. Hennems established herself at the village of Waveney.
HEM

near Liverpool, in the expectation of obtaining good schools for her children and pleasant society for herself. She had little success in either of these objects. The schools were not such as she wished for; her house was inconveniently small; she was annoyed by visitors, prevented from attending social parties, and complained with some bitterness of 'this weary celebrity.'

In the early part of the summer of 1829 Mrs. Hemans paid a visit to Miss Abbeville's school in Edinburgh, where she proceeded to Chiewford, in Roxburgshire, the residence of the author of 'Cyril Thomson,' and was there introduced to Sir Walter Scott, with whom she afterwards spent several days. She returned to Edinburgh in August, and thence proceeded home to Wavertree.

In 1830 she published another volume of poetry, 'The Songs of the Affections,' and in the same year paid a visit to the lakes of Cumberland and Westmorland. She remained a fortnight with Worthaworth at Rydal Mount, and then took up her residence at Dove-Nest Cottage, near Ambleside. After remaining some weeks, she was induced to make a second visit to Scotland, on which occasion she spent the greater part of the time at Milburn Tower, the seat of Sir Robert Liston. During this visit she formed a friendship in consequence of which she was induced to visit Dublin before she returned to Wavertree, and ultimately decided on leaving England, and fixing her abode at Dublin.

In the spring of 1831 Mrs. Hemans left England for Dublin, where she took lodgings. Her health, from the time of her leaving England, had been rapidly improving, to which the advancing age of the sons remaining under her care was an additional cause of anxiety. 'My position,' she writes, 'obliged as I am to be a stormy world alone,' precluded her from any more hopeful life which was her desire.' In November, 1831, after a visit to her brother in Kilkenney, she writes thus to a friend in England:—On my return to Dublin I became a sufferer from the longest and severest attack of heart-ailment which I have ever experienced. It was accompanied by almost daily fainting fits, and a languor quite indescribable. 'And not long afterwards, in another letter, she says:—'The constant necessity of providing sums of money to meet the exigencies of the boys' education has obliged me to waste my mind in what I consider were desperate effusions,'

'Pouring myself away,'
As a wild bird amidst the falcon's tears
That within him thrills and beasts and burns
For all who have a heart.'

The latter months of 1833 were busily spent by Mrs. Hemans in arranging and preparing for publication the three collections of her poems which were published in the spring and summer of 1844, 'Hymns for Childhood,' 'National Lyrics and Songs,' and 'Scenes from the Lives of Napoleon.'

In August, 1834, Mrs. Hemans took the scarlet fever, and when imperfectly recovered, caught a cold; she was seriously indisposed, and never left her bed till she was subdued by her last fit. It was the illness which virtually decided she had caused an unequivocally dangerous aspect. The summer residence of the Archbishop of Dublin was placed at her disposal; change of scene and the kind attentions of the archbishop and his wife afforded some relief, but no permanent benefit; and in order to be near to her physicians, she was taken back to Dublin.

On the 26th of April, 1835, Mrs. Hemans dictated her last poetical effort, the 'Sabbath Sonnet.' She continued to sink gradually till May 12, 1835, when, after a long and quiet sleep, she died without a sigh or movement. She was buried in St. Anne's Church, Dawson Street, Dublin, which is closed by a tablet engraved on which she died. A tablet was erected by her brothers in the cathedral of St. Asaph, in memory of Felicia Hemans, whose character is best portrayed in her writings. A volume of 'Poetical Remains' was published after her death.

Mrs. Hemans could hardly be called a beautiful woman, but her personal appearance was very pleasing. In early youth she was greatly admired for the brilliance of her complexion, her golden hair, and her remarkably clear and mobile face. The latter and more golden hair, in her mature years; her hair darkened into auburn, of a silk-like softness, and very long and abundant. In her aspect and movements there was something more than natural animation. She was notacute and incisive, but she was sensible and unreservedly honest and open to the general society. Her family, a few friends, her music, her books, and her poetical pursuits, were her chief sources of enjoyment. She played on the harp and piano-forte, and about the time when she went to reside at Wavertree, discovered in herself a faculty which gave her much gratification—that of composing melodies; she could sometimes find passages of fine music for some of her poems, and sometimes set to music a song or lyrical piece already written. Among her friends she was distinguished by much vivacity and a very delicate wit. She was kind and unaffected in the exercise of her many charities towards the other female writers of her day, with most of whom she was on terms of friendship, either personal or by correspondences—with Joanna Baillie, Miss Milford, Miss Londonderry, Mary Lamb, Mrs. Thrale, Mrs. Bannister, Mrs. Howitt, and others. Mrs. Hemans's love of the art to which she had devoted herself was intense, and her appreciation of it was serious and high, as a means to purify and elevate the mind. In her later years her religious impressions became stronger, and her poetry became more tinted with religious thoughts and feelings. Her knowledge was extensive, but it was not philosophical or scientific knowledge. Poetry was the object of all her studies, and she sought for its materials in history, voyages and travels, and the fine arts; but her especial delight was to contemplate the scenes of nature in all their aspects of beauty, and to muse upon the associations and poetical and philosophical contemplations which, fascinating and unbounded, are never vague or indistinct, and always seem to flow naturally from the scene or circumstance present to her mind. She is most successful when the subject is nature, something she usually calls up the sympathies which are familiar to her. In foreign subjects she is less effective. Her poetry is thus peculiarly and strikingly the representation of her own character, of whose the most characteristic is that of a lover of sweet and lyric and descriptive, filled with imagery, sometimes overflowing with it. She has no dramatic power; she cannot enter into the thoughts and feelings of others: she can only exhibit her own. She is not tragic, and she is no epic poet; the actions and sentiments of the characters are above nature or out of it, and the diction is not dramatic, but poetical, and monotonously uniform from prince to peasant. Her verisimilitude has three distinct styles. Her 'Domestic Affections,' and other early poems, are obviously modelled on 'The Pleasures of Hope,' of Campbell; her 'Tales and Historical Scenes,' and other poems of the middle period, are in the manner of Byron, less flowing than her early style, but more vigorous. Her last style is her own, and whether in blank verse, in couplets, rhymes, in stanzas, or sonnets, or in the varied measures of lyric poetry, exhibits in its free and continuous flow a perfection of rhythmical melody which in sweetness and fullness of sound has never been surpassed. In uninterrupted reading, however, it has a tendency to cloy uniformity. Her great defect is the similarity of tone and expression in all her works. Many of her lyrical pieces are exceedingly beautiful. (Chorley, 'Memoirs of Mrs. Hemans; HEMEROBIUS, a genus of insects of the order Neuroptera and section Planipennia. The genus, as established by Linnaeus, has been dismembered by subsequent entomologists, and is now equivalent to a family distinguished by the filiform antennae and by the number (four) of the palp of the insects included in it. They have soft slender bodies, much exceeded in length by the large rounded wings, which, when the animal is at rest, are folded. Their eyes are globular and vividly metallic. The larve are ferocious in habit, and prey upon plant life, seining them with their powerful jaws and sucking their prey to death. When full grown, the larve hew themselves into the soil, and pupa. The eggs of Hemerobius are deposited on plants, and are pedunculated, so as to resemble fungi, for which they have sometimes been mistaken. These insects range from Europe to Australia, and there are about seven species native of the British Isles.

HEMICIDARIUS, a genus of fossil Echinozoa, from the col tit.

HEMIPNEUSTES, a genus of fossil Echinodermata, from the chn.

HEMIPHYTRA, a genus of fossil Polyazaria, in the beds of Devonshire, allied to Fenestella. (Phillips.)

HEMILING, HANS. [EMLING, HANS, F. C. S.]

HEMILING, HANS. [EMLING, HANS, F. C. S.]

HEMILING, HANS. [EMLING, HANS, F. C. S.]
afford, he was apprenticed to a writer (or attorney) for six years. At the end of this term he was sent to Edinburgh, at the age of twenty-one, to complete his legal instruction. He was then apprenticed to Mr. John Clerk of Eldin, the Earl of Lauderdale, and the Lord Advocate Jeffrey, and in these employments he continued to 1831.

During his residence at Dundee he acquired a taste for practical astronomy, as well as for the history and literature of that science. At Edinburgh he frequented the observatory, then a small and insecure building, to which he applied to give valuable opportunities to a learner. Weak health and a tendency to disorder in the eyes are very poor aids to an astronomer, but they did not hinder Mr. Henderson from bringing himself into notice, though his scientific pursuits could only be the relaxations of a life of business. In 1824 he began to communicate with Dr. Thomas Young, then superintendent of the Nautical Almanac, whom he assisted both by methods and calculations. The consequence was, that at Young's death it was found that he had placed in the hands of Professor Rigaud a memorandum desiring that the Admiralty might be immediately informed, as soon as his death should take place, that he knew of no one more competent than Mr. Henderson to be appointed his successor. The government, however, confided the trust to Mr. Pond, the astronomer royal, who immediately offered Mr. Henderson to succeed him in the charge of the observatory at the Cape of Good Hope, and later in the post of Astron. Adm. When the date of his arrival at the Cape, he must be considered as a professional astronomer.

After vigorous application to his duties for little more than a year, he found his health and spirits give way. His isolated position and separation from his family, accompanied by the knowledge that he was subject to a disorder of the heart, which might at any time, and which finally did, prove fatal, made him wish to return to Scotland. He came back accordingly in 1833, with a rich store of observations, the refection of which he imposed upon himself as a voluntary duty. In 1834, by an agreement between the government and the Astronomical Institution of Edinburgh, the latter gave up their observatory to the University, the former agreeing to appoint and provide for an astronomer, who was also to hold the professorship of practical astronomy in the University. On the recommendation of the Astronomical Society of London, to whom Lord Melbourne applied for advice, Mr. Henderson was appointed the first astronomer royal for Scotland. Here, in the midst of his friends, and in the position which, of all that could have been imagined, he would have chosen for himself, he pursued his observations and researches till his death, which took place suddenly, November 20, 1838.

A very full account of Mr. Henderson's astronomical writings will be found in the annual report of the Astronomical Society for 1846, with a list of his writings, which consist of papers on the determination of the parallaxes of magnitude and importance, to different scientific publications, independently of the volumes of observations which issued from the Edinburgh Observatory. We might particularly what he did on occultations, on the solar and lunar parallaxes, &c.; but it will better suit our limits and the nature of the subject, to refer the reader to the memoir just cited, and to confine ourselves to a mention of the manner in which his name is connected with the discovery of the parallaxes of the fixed stars. [PARALLAX, P. C. J. M. HEN- Derson, when at the Cape, repeated the attempt in which Brinkley had failed, namely, the detection of the effect of parallax upon the motion of the stars. The results were a' and a Centauri; and the results derived from the former star show discordance, both in right ascension and declination, very much resembling those which parallax would cause. Mr. Main, in his elaborate investigation of the modern claims upon this subject (Mem. Astron. Soc. vol. xii.), says that in the event of a parallax at all comparable to that anticipated by Mr. Henderson, it would tend to the star, he will deserve the merit of the first discovery. Mr. Maclear, Mr. Henderson's successor, made a new series of observations on the same stars, with a different instrument, from which Mr. Henderson produced results very nearly agreeing with his own.

The private character and social qualities of Mr. Henderson are among the pleasant recollections of those who knew him. In his astronomical career he resembled his friend Mr. Baily in bringing to his profession a spirit of independence; and his intercourse with Mr. John Clerk of Eldin, the Earl of Lauderdale, and the Lord Advocate Jeffrey, and in these employments he continued to 1831.

During his residence at Dundee he acquired a taste for practical astronomy, as well as for the history and literature of that science. At Edinburgh he frequented the observatory, then a small and insecure building, to which he applied to give valuable opportunities to a learner. Weak health and a tendency to disorder in the eyes are very poor aids to an astronomer, but they did not hinder Mr. Henderson from bringing himself into notice, though his scientific pursuits could only be the relaxations of a life of business. He was well acquainted with astronomical literature, and with other branches of science; and at different times supplied the places of the professors of mathematics and of natural philosophy in the University. He formed a great attachment to the methods of the German astronomers, and his models were MM. Bessel and Struve.

HENRICO CATTERINO DAVILA, born at Pieve di Sacco near Padua, was the son of Antonio Davila, who was great constable of Cyprus when that island was taken by the Turks from the Venetians in 1571. Antonio emigrated to England, where he had relations, and afterwards to France, where he won the favour of Catherine de Medici, and of her son King Henri III. Lastly he went to reside in the Venetian States, where a son was born to him in 1597. In 1618 he received the title of Sir Henry Davila, in the year of his death, and was severely wounded at the siege of Honfleur. In 1599 he was recalled to Pieve di Sacco by his father, who soon after, in a fit of temporary insanity, put an end to his life by throwing himself out of a window. Not long afterwards Henrico entered the military service of Venice, and was employed successively in Candia, Friuli, Dalmatia, and other stations. In 1631 he was appointed to take the command of the garrison of Crema, with or without the assistance of the postmasters on the road to supply him with every conveyance required for the service. On arriving at the stage of St. Michele, near Verona, the postmaster refused to furnish the necessary accommodations. High words ensued, and the postmaster fired a pistol, and shot Davila dead in sight of his wife and children. One of Davila's sons attacked the murderer, and killed him on the spot; others were wounded in the affray, and the chaplain of Davila was also slain.

Davila is known to the world through his History of the Civil Wars in France, 'Storia delle Guerre Civili di Francia,' from the death of Henri II. to the peace of Vervins in 1598, a period of forty years most eventful in the history of that country. Ho trends, therefore, upon the same ground as De Thou in his 'Histoire sui Tempora.' Some critics have noticed that Davila had a great passion for novelty, and especially for Catherine de Medici, who had been his father's benefactress. The facts, however, stated by Davila are acknowledged to be true, and he was well acquainted with them through his uncle, who was a soldier in the French army. He was familiar with the politics of his age, and with the leading contemporary characters. He was also well acquainted with the topography of the places in which most of the events which he narrates occurred. His style is graphic and animated, especially when he describes a popular insurrection, a combat, or the storming of a town. His account of the massacre of St. Bartholomew may be quoted as a specimen. Apostolo Zeno, comparing Davila with Guicciardini, observes, that whilst the prolixity of Guicciardini in dwelling minutely upon minor matters becomes wearisome to the reader, the course of Davila's narrative runs on uninterrupted, adapting itself nimbly to circumstances of subordinate importance, and dwelling chiefly upon those on which he has materially affected the interests either of religion or the state. By common consent Davila is numbered among the best historical writers of Italy. His work has gone through many editions, and has been translated into several languages. Apostolo Zeno published a splendid edition of it in 2 vols. fol. Venice, 1735, to which he has prefixed a life of the author.

(Tiraboschi, 'Storia della Letteratura Italiana;' Corniani, 'I Secoli della Letteratura Italiana.')

HENRYSON, ROBERT, a Scottish poet of much merit, lived in the latter part of the fourteenth century, but of whom hardly anything is known. He is supposed to have been the
HER

HER

Robert Henryson whose signature as notary-public is attached to a charter granted in 1478 by the abbey of Dunfermline, in Fifeshire; and he is elsewhere said to have been a schoolmaster in that town. It has been inferred that he must have been the son of a merchant, and it is consequently supposed that he might have been a Benedectine monk. In a poem of Dunbar, printed in 1508, he is spoken of as dead; and in one of his poems he had described himself as a 'man of age.' His tale of 'The Pattern and Proper of the Duke of Chevreux' appears in a manuscript of the manuscript of that poet's works. His beautiful pastoral of 'Rohin and Makyne' is known to most readers from Percy's 'Reliques.' Other specimens of Henryson's poems are in Sirball's 'Chronicle of Scottish Poetry,' in Dr. Irving's 'Lives of the Scottish Poets,' and in Elia's 'Specimens.' The fullest collections of them, however, are in Lord Hailes's 'Ancient Scottish Poems,' 1770, and in a volume containing his thirteen poems, called 'Fables,' edited by Dr. Irving in 1829, for the Bannatyne Club. For that club, in 1824, Mr. George Chalmers had edited the 'Testament of Creeseide,' and 'Rohin and Makynie.' Henryson writes with much greater purity and correctness than many of his contemporaries; his verison is good, and his poetical fancy rich and lively.

HEPATITIS. [LIVER, DISEASES OF, P. C.]

In many genus of Euphorbiaceae belonging to the natural order Umbelliferae and the tribe Paeoniaceae. The calyx consists of 5 minute teeth, the petals abscindate with an infixed point, the outer ones radiant. There are 34 species of this genus recorded, but only one on record in Great Britain, and few are applied to any useful purpose.

H. Sphekkidium, Cow Parfarn, has ternate pinnate leaves, the leaflets lobed or pinnatifid, cut, and serrated. The stem is about four feet high, the lower leaves very large, and the flowers white or reddish. It is a native of Europe, and probably of Siberia, and is found plentifully in the meadows and hedges of Great Britain. The whole plant affords wholesome nourishment for cattle, and is collected in Sussex for feeding hogs; hence it is sometimes called hog-cow. Cows and rabbits are also fond of it, and horses will sometimes eat it, but it does not appear to be so agreeable to them. The Kautehatabales and Roxians are in the habit of using the shoots and leaf-stalks as food, after the rind, which is bitter, has been taken off. They collect large bundles of the plants, and during the process of drying the stalks become covered with a sarchacetic efflorescence which is esteemed a great delicacy. The Russians distill an ardent spirit from the stalks thus prepared by first fermenting them in water with hibisberry. The seeds of the plant are diuretic and stomachic, and exude a poisonous oil.

H. pubescens has ternate leaves, somewhat pubescent beneath; the leaflets toothed and pinnatifid; the umbels of many rays; involucres from 1 to 2 leaves; the fruit elliptic, having the hairy exocarps. It is a native of Caucasus in mountainous places, and of the Caucasus in alpine places. The young shoots are filled with a sweet aromatic juice which is eaten by the natives of the Caucasus in a crude state.

H. Pyrexicum has large leaves, tomentose beneath; the leaflets lanceolate, toothed, or serrate; the involucres of few leaves; the young fruit covered with long hairs; the matured ones glabrous and nearly orbicular. It is a native of the Eastern and Central Pyrenees, and of Italy. Don thinks that this plant is identical with the H. gummiferum of Willdenow, which was supposed to yield the gum ammoniac of commerce. Don has however identified the plant which yields the gum, and has placed it in a new genus. [Doxeuma, P. C. S.]

All the species of Heracleum grow well in any soil, and are easily propagated by seeds or by dividing the root. (Common name and Botany: Bathington, Manual of British Botany.)

HERACLITUS, Roman emperor from A.D. 610 to 641. Since the publication of the volume of the Penny Cyclopaedia containing the life of this great emperor, the importance of Asia Minor and the adjacent countries as regards Europe has been much increased, and accordingly it appears useful to give more particular details of his campaigns from the point of view of the Persians, which are of equal interest for the historian, the geographer, and the soldier.

The destiny of the condition of the empire at the accession of Heraulitus compelled him to be an almost incoherent spectator of the minuscious invasions of the Avars in Europe and the Persians in Asia. By submitting to an annual tribute of one thousand talents (pounds?) of gold, as many talents of silver, one thousand sildes of silk, and a thousand slaves, the Avars and the Persian king Chorosro or Chosroes to discontinue his invasions of Asia Minor and to be satisfied with the conquests he had made from the Greek empire, which comprehended Egypt, the country of Sardis, and the rich countries of the Black Sea, which were drawn from the northern borders of Syria to the eastern extremity of the province of Pontus. Heraulitus made a less humiliating peace with the Avars. Having got rid of his Persian conquerors, the Avars were not left alternately in the eastern and western provinces of the empire. The Tartar was a Tartar, and the Persian was a Persian. As in the case of the Tartar, so in the case of the Persian war, the Persians were always sparing the property of the churches; and he was thus enabled to raise an army strong enough to stop all further designs of the Persian king. The plan of attacking that powerful foe was bold and well designed, and it was executed with so much boldness and prudence, and such a startling combination of offence and defence, as to equal the strategic operations of the greatest generals. A powerful Persian army was stationed in the valley of the Upper Euphrates ready to descend through the passes of the Anti-Taurus into the high plains of Cappadocia, and to push on towards Constantinople as they had done in A.D. 610. History does not mention the army of the Persians, consisting chiefly of light infantry, in which the government was quartered in the environs of Constantinople, and afterwards in those of Chalcedon on the Asiatic shore of the Bosporus, and which were well prepared for a campaign. But Heraulitus was master of the sea, and his fleet was designed to enable him to choose his base of operation. Early in the spring of 622 he embarked his troops, and from the Bosporus he sailed to the eastern corner of Syria, which lies to the north of the island of Iskinderon (Alexandria), and is protected on the north and east by the Taurus and on the south by Mount Amamus. There on the plains of Issus he continued accustoming his troops to actual warfare by making them manoeuvre in the same way as modern troops do, and he occupied the Cilician and Syrian gates and other passes that lead through the surrounding ranges. A Persian army approaching in full confidence of making the coming campaign of war, or of forcing them to re-embark, was turned, routed, and driven into the mountains of Armenia. Having thus cleared his way and secured his rear, Heraulitus marched through the Cilician gates northward in the direction of Mount Argeus (Argilea) and the Upper Halya (Ktitel Irmak), where, as it seems, a portion of his troops remained during the winter as a body of observation. The emperor with the main body advanced upon Trebizond, and quartered his troops in the town, which now became the centre of his operations. He left it, however, soon after his arrival, sailed to Constantinople, and in the following spring of 623 returned with a fleet and a chosen body of troops to the coast of Asia Minor. It is important to note for conveying his army by sea to the south-eastern extremity of Asia Minor, and thence fighting his way through inaccessible mountains right across Asia Minor to the Euxine, if nothing else in his campaign was important. It is important to note for it seems that he could have gone there directly from Constantinople without incurring the risk of losing half his army, or perhaps the whole of it, in the defiles of the Taurus and Anti-Taurus. Our sources say nothing of his motives, but generally we know few details of his first campaign. However, if we take the state of the empire into due consideration, and draw conclusions from his subsequent campaigns as to his first, we cannot hesitate to believe that Heraulitus intended to attack Persia from two points, each of them equally well situated for an attack and affording equal security in case of a forced or voluntary retreat. And it becomes no less probable than probable that he was unable, to prevent the lay of Iskinderon from being the embarkation, and thence marched towards the Euxine, because he wanted to relieve, through his presence at the head of an army, the minds of those of his subjects who were most exposed to the attacks of the Persians, and to occupy as many mountain-passes as possible in order to prevent the Persians from breaking through the defiles between Cappadocia and the Upper Euphrates. In this case, however, his plan of campaign failed. The plan of his campaign further shows that it was corroborated by many subsequent wars, namely, that the inland tract between Trebizond and Issus is unfit for operations on a large scale, and that the coast of Asia Minor and the districts of Cilicia and Syria may be successfully invaded by an army coming from Asia Minor are the eastern extremities of Pontus and Cilicia, whence it is evident that a power which is master of the sea,
especially the Mediterranean, and lands sufficient forces as either of those points, will effect or prevent the conquest of all Asia Minor and the adjoining eastern countries with less force and in a shorter time than any power which is only a land power. Caesar, therefore, prepared to march to Cilicia as his principal base of operation, and attacking Persia from the north, Heraclius further intended to compel his rival to withdraw his advanced troops from Syria and the or the chief fortified, and, with the Persians moving westward dominion, and thus to relieve his subjects and increase his means.

From Trebizond Heraclius carried the war, in the spring of 622, across Asia Minor into Phrygia. The Persians, we know, did not pursue him, and the Thebans were his allies, and he had entered into negotiations with the khazars beyond the Caucasus. These were the causes of his first advancing north-east into the Caucasian provinces, and only after having shown himself there and increased his army through the contingents of his allies, he marched south upon Charas (Kars) and thence in a direction parallel with the Araxes as far as the great head of that river, where, after a south-eastern and eastern course, it turns north-east. Thence he marched right upon Gazarra or Gaudzacs, which is the still common Armenian name of Tabris, and this city fell into his hands with all its wealth, Choroseres, with a very large part of its population. He then moved north, turned the Persian army and fell upon their rear, took and destroyed the Tchobars, now Urmischeh, near the western shore of the large lake of Urmischeh, which is said to be the birthplace of the sacred fire of the Persians, and the site of the battlefield of 626, where Heraclius had been victorious for its vast pastureages, for the support of his numerous cavalry, and for the purpose of having an easy communication with the Inhabitants of Asia Minor, and the Iron Gate, near Derbent, whenever they invaded Persia.

In the following year, 623, Heraclius penetrated into the heart of Media, took Cassin, and probably also Asphalt (Isapshin), defeated Chorores in a pitched battle, and, after having captured the Roman arms further into Persia than any of his predecessors, returned to his former winter quarters at the foot of the Caucasus.

Our knowledge of the campaign of 624 is very imperfect; the accounts in the sources are vague and scanty, and the whole is so obscure that D'Anville gave up the idea of investigating it critically.

Meanwhile Chosroes had withdrawn his troops from Egypt and Syria, and thought himself strong enough to act on the offensive. In the spring of 625 he ordered his lieutenant Sarbar, or Sarbarra, to menace Asia Minor, while he himself prepared to move against the Caucasus. Sarbar was in Northern Mesopotamia; however, he did not take his way through the inland tract, which he could have done either in the direction of Dyjakebr, Maldeythe, Sivade, and Amasia, through the province of Sophene and the north-eastern part of Cappadocia, or in the direction of Marash and Kaisriseh through the centre of Cappadocia; but he marched south-west and fell upon the eastern angle of Cilicia. His intention was apparently to take the easiest way for penetrating into Asia Minor, to cut off the communication between the Romans in the fortresses of the Rhodopean Mountains, and the Mediterranean, and to destroy the magazines of the Romans in Cilicia. Informed of this diversion, Heraclius moved on; but while he appeared to threaten the main body of the Persians under Choresmes, he suddenly passed by, left the defence of Armenia to his Caucasian allies, and followed Sarbar through Mesopotamia, either by his track or on a parallel road. They met in Cilicia on the banks of the Sarus, now Shihun, at a moment when Sarbar was in a very critical position, for although we do not know whether he entered Cilicia through the Syrian gates, or through the valley of the Pyrusmus or Jhith, it is evident that either one or both of these passes were already450 occupied by the Persians, while the Roman forces were scattered, and the defiles of the Cilician passes, which were defended by Roman troops. Theophanes says, that Heraclius approached from Germania (Marash) passed by Adana, and arrived in Cilicia before Sarbar, and as, when the battle began, the Romans were on the right and the Persians on the left bank of the Sarus, we may suppose that Sarbar came through the Syrian passes and found himself in presence of the main army of the Persians, but when he was going to attack the Cilician passes. In the following battle Heraclius annihilated both his own and his enemies' troops by his valour and the number of his warriors, and left nobody dared to fight. After a bloody conflict the Persians were routed; and Sarbar escaped, through the Spanish passes, with the scattered remnants of his army to Persia. Heraclius pursued him, but did not pursue him, and took his winter-quarters in Persia.

The next campaign of 625 equals the most splendid military operations in antiquity or modern time. In its grand outlines it may be compared to the operations of Hannibal and Scipio in a.c. 204, and to Napoleon's campaign in France in 1814: Hannibal was still in sight of Rome when Scipio boldly sailed to Africa; and the allies were fast advancing upon Paris, when Napoleon turned them and marched towards Germany: under similar circumstances Heraclius was more fortunate than either Hannibal or Napoleon, and it is only just to say, that he stood the fortune in the same light as the effect of his superior genius. Early in 626 Chorores opened the campaign with two armies against Heraclius, and a third under Sarbar, who was commissioned to attack a second army of Persians, stationed on the border of the whole peninsula, and reached the walls of Chaledon, opposite Constantinople; and, at the same time, a host of more than a hundred thousand Avars and other barbarians, under a new king, Ali, was approaching from the west, and twelve times assailed its walls. Choresmes hoped to induce Heraclius to hasten to the success of his capital, but the emperor stood firm at the foot of the Caucuses, dispatching however, by sea, twelve thousand armed horsemen that trampled safely at Constantinople. He knew that, however great the danger was for Constantinople, the Persians and Avars had no ships to effect a union, and that the inhabitants of the capital would fight to the last before they surrendered to an enemy whom it was more dangerous to encounter in the open field than in their assails within walls and towers. A Slavonian fleet having entered the Bosporus, destined to convey the Persians over to the European shore, the Greek galleys left the Golden Horn, and, in sight of the besiegers, destroyed the ships of the barbarians or took them and carried them off into the harbour of Costantinople. Shortly after this event the Avars withdrew and Constantinople was free, although Sarbar continued to amuse himself with the siege of Chaledon.

While this took place in the west, Theodore, the brother of Heraclius, defeated the Persian general Said, in Armenia, and the emperor defended with success the Caucasian provinces against the desperate attack of Choresmes, who took the field in company with the Avars, and defeated an army of 50,000 men near Tiflis. Another army of Khazars invaded Persia on the side of Turkestan. The united Romans and Khazars were 70,000 men, or perhaps more, since the Khazars alone were 50,000, and Heraclius led them forthwith into the province of Artaxiyatape, where he took up his winter quarters. He crowned the success of his arms by a stratagem which proved more advantageous than the winning of a battle. The king of the Khazars, and, by order of the Romans and the Khazars, Choresmes sent a dispatch to Sarbar, with an order to give up all further designs against Constantinople, and to join him without delay in Persia. The messenger having fallen into the hands of the Romans, Heraclius altered the dispatch, enjoining him to hold out as long as possible, and the letter was forwarded through another courier. Sarbar continued the siege, but his protracted absence irritated the king so much that he dispatched a second messenger to the first lieutenant of Sarbar with an order to kill his general as a traitor. This dispatch having been delivered to Sarbar instead of his lieutenant, he added the names of four specious orders of the Persian king, and offered himself as the slayer of his master, whereupon he showed them the order, and declared the only way to save themselves was to break their allegiance to Choresmes and the Khazars and make peace with the emperor on their own account. The officers gave
HERBERT, JOHANN FRIEDRICH, a distinguished German philosopher, was born in 1770, at Oldenburg, where his father at the time held an office connected with the administration of the University. There is some reason to suppose that he was born from a man well acquainted with the philosophical systems of Leibnitz and Kant, Herbert, at the age of about twelve, was led to speculate upon such subjects as God, freedom, and immortality. It is likely that Leibnitz's Monadology, as recommended by Jena, where he studied under Fichte, and formed an intimate acquaintance with him, and he entertained the highest opinion of his master until Schelling's work, 'Von Ich,' fell into his hands, and, although at first it appeared to him, in his opinion, to progress was slow, he was successful in every siege and engagement. He came from the province of Atropatene, passed the Zebas (Great Zebas) in its upper part, and marched towards Nisibis (Nimroud Misul), where he encountered the Persian army commanded by Rhazater, who had followed the emperor for some time, but gained some marches over him, and had taken a position near the ruins of Nisibis with the intention of preventing the Romans from occupying the valley of the Tigris and marching upon Ctesiphon. After an obstinate resistance from daybreak till night Rhazater was routed and killed, and Heracleius, who had again signified himself as a general and a warrior, pursued the fugitive enemy, and occupied the bridges over the Great and the Little Zebas, which the Persians had no time to secure. The battle at Nisibis was fought on the 12th of December, 627. On his way to Nisibis, he defeated the Persians at Arela, where he captured, plundered, destroyed the royal palaces of Issus, Begall, and others, and immense treasures fell into his hands. Soon afterwards he took Dastagerd, the favourite residence of Chosroes, and its treasures. The Persians fled to the desert of Theophrases given in thousands and many thousands of captives, chief inhabitants of Edessa and Alexandria, as also three hundred standards and other trophies taken from the Romans in former campaigns, captured by his victors. Chosroes fled from Dastagerd to Ctesiphon (El-Moalim), and thence into the interior of Persia. Heracleius was already in sight of the Zebas, when he suddenly retreated north-east upon Sizaura (Shiraz) and Gomorrah, crossing the Assyrian mountains in the midst of winter without loss. The motives of his retreat were either the fear of being unable to take the well fortified city of Ctesiphon, the winter, the want of provisions in Assyria, which had been ravaged, being already very sensibly felt, or perhaps the rebellion of Syria against his father Chosroes, whom he treacherously seized and put to death with eighteen of his sons, the brothers of Siroes. (February 23th, 628.) In the month of March following peace was concluded between Siroes and Heracleius. Siroes ceded Syria, Egypt, Mesopotamia, and Armenia, and gave back the Bosphorus to the Persians in his father's time. And Heracleius gave up many thousands Persian captives, and allowed the Persian soldiers who still occupied the principal towns of Egypt, Syria, and Mesopotamia to return to their homes as their subjects were treated in a humane manner through the Roman provinces. In the same year Heracleius had his triumphal entrance in Constantinople. Theophanes, so vague and obscure in his accounts of the first campaigns of Heracleius, gives a detailed and accurate description of the campaign of 627. It is not in the plan of this article to relate the particulars of the latter part of the reign of Heracleius, during which he lost all his conquests, which fell into the hands of the Arabs. A colossal statue of Heraclius existed at Barletta in Puglia so late as the end of the fifteenth century.

(Theophanes, p. 250, &c.; Nicephorus, p. 4, &c.; Cec- damon, vol. i. p. 276, &c.; Zonaras, vol. ii. p. 29, &c.; Gibbon, Decline and Fall; Lebègue, Histoire du Bas Empire; D'Anville, Recherches Géographiques concernant l'Expedition de l'Empereur Heracleius en Perse, in the Memoirs of the Académie des Inscriptions et Belles Lettres. The map of Asia Minor and part of Persia, in Kinneir's Journey through Asia Minor, Armenia, and Kurdistan, indicates the route taken by Heraclius in his campaigns, but there are not wanting some critical comments on the expeditions of Heraclius, which would offer less difficulties now than it did to D'Anville, since our knowledge of the country is more exact than it was a hundred years ago.)
nations, such as the ideals of perfection, benevolence, malicelessness, justice, compensation, equity, and the like. In his metaphysics, Herbart points out three problems containing contradictions, viz., things with several attributes, change, and the like. He shows that these are contradictions, and to make the external and internal world agree and harmonize so as to become conceivable, he assumes that the quality of everything existing (das Seienden) is abstract. He draws an analogy between the objects referring to space and time, but they stand in relation to a something, which is the essence of things. Wherever this essence consists of a plurality of attributes, there must also be an abstract. We must therefore assume that many simple things or beings are the principles of all things in nature, and the latter, consequently, are nothing but aggregates of simple things. They exist by themselves in space as far as it is conceived by our intellect, but not in physical space, which contains only bodies. We do not know the real simple essence of things, but we may acquire a certain amount of knowledge concerning internal and external relations. When they accidentally meet in space they disturb one another, but at the same time strive to preserve themselves; and in this manner they manifest themselves as powers, although they neither are powers nor have powers. By means of these principles Herbart endeavored to reform the whole system of psychology which he found established by his predecessors; for, according to him, the soul too is a simple being, and as such it is and remains an abstract, and it is neither subject for speculation nor for experimental psychology.

There is nowhere any plurality of attributes, nor has it any power or faculty of receiving or producing anything; and the various faculties which are supposed to have been created by an act of consciousness, reason, &c., which sometimes are at war and sometimes in concord with each other, are, according to Herbart, mere fictions of philosophers. In like manner he denies that it possesses certain forms of thought or laws regulating our desires and actions. The soul as a simple being, and in its accidental association with others, is like the latter subject to disturbance and exerts itself for its own preservation. The latter determines the quality of every object, and he endeavours to deduce and calculate the whole life of the soul, with the aid of mathematics, from these mutual disturbances, checks, and from its reactions against them. Hence he is obliged to deny man's moral or transmortal freedom, although he allows him a certain free character. He maintains the immortality of the soul, because the simple principles of all things are eternal; but he denies the possibility of acquiring any knowledge whatever of the deity.

"Nearer Werke der Deutschen; Brockhaus, Conversations-Lexicon."  

HEREDITAMENT. (Chatez, P. C.; Descent, F. G.; Erat, E. F.; Heise, E. F.)  

HERESY. The word is the English form of the Greek ἡδηρεσία (airosis). It signifies literally a "choice," and hence it came to denote an opinion on any subject; and it was used to express a sect in philosophy. The word occurs in the New Testament, sometimes simply to denote a religious body, and sometimes as a term of reproach applied to the religious opinions of persons which differed from the opinion of him who used the term. When ecclesiastical councils determined what was the orthodox or Catholic faith, then Christians who would not acknowledge the decisions of such councils were called Heretics, and their guilt was expressed by the term Heresy: those who reject Christianity altogether are infidels and unbelievers.

The fifth title of the first book of the Code of Justinian contains penalties against Heretics, Manichæans, and Samaritans, which, in some cases, extended to death. Heretical books were ordered to be burnt. Before the Reformation in England heresy was defined as holding opinions contrary to the Catholic faith and the determination of Holy Church: at least this is the definition of heresy in the statute 2 Hen. IV. c. 15. The court in which a man could be convicted of heresy, according to this statute, was the court of the bishop in a provincial synod. After conviction the criminal was delivered up to the king to do what he pleased with him. If the criminal had adjured his heresy and then relapsed, the writ De Haeresiaco comiendo, upon which the criminal was burnt alive. One Sawtre, it is said, was the first man burnt alive for heresy in England, and the writ De Haeresiaco comiendo was formed in his case. But the statute 2 Hen. IV. c. 15, empowered the diocesan alone, without a synod, to commit a man for heretical opinions, and to imprison him as long as he chose, or fine him; or if he refused to adjure, or if he repeated the heresy, the sheriff, or other officer, who should be present, if required, with the ordinary or his commissary, when the sentence was pronounced, was to take the convict and burn him openly, without waiting for the king's writ.

It is unnecessary to mention the statutes of Henry VIII. relating to heresy. The Reformation was not fully established till the reign of Elizabeth. It appears from the statute 26 Eliz. c. 1, that the persons to whom the queen or her successors shall give authority to judge of heretics shall not declare any matters to be heresies except such as heretofore hath been adjured heresy by the authority of the canonical Scriptures, or by the first four general councils, or any of them, or by any other general council wherein the same was declared heresy by the express and plain words of the canonical Scriptures, or as shall hereafter be approved of by parliament with consent of the clergy in conviction. But there is no statute that determines what heresy is. After this statute of Elizabeth the proceedings in cases of heresy remained as they were at common law; for this statute repealed all former statutes about heresy, which was accordingly punished, after the Reformation was fully established, by ecclesiastical censures, and by burning alive a criminal who had been convicted, in the manner above described, in a provincial synod. The writ for burning the heretic could not be demanded as a matter of right, but was left to the discretion of the crown; and both Elizabeth and James the First, in their decrees, though they declared heretics to be burnt, said, burnt alive two Anabaptists, and James burnt alive two Armins.

The statute of 28 Charles II. c. 9, abolished the writ De Haeresiaco comiendo. Heresy is now left entirely to the ecclesiastical courts; and the punishment of death in consequence of any ecclesiastical censure was by that act abolished in England. As Elizabeth and James preserved, showed their approbation of burning heretics alive, so Lord Coke (3 Inst. c. 5) approves of the punishment.

At present the ecclesiastical courts punish for heresy, when they do punish, pro salute animae, as it is termed—that is, solely out of regard to the soul of the offender. But it is difficult to say at present what can be called heresy; and perhaps it is difficult to say what is exactly the punishment for it. It is remarked by the Report of the Committee of the House of Commons on Penalties and Disabilities in regard to Religious Opinions, 1845 (p. 22), that 'the jurisdiction, as it may affect the laity, and clergy not of the established church, or indeed as administered pro salute animae, appears to militate with the principles contained in modern acts of toleration, that are inconsistent with the infliction of punishments for mere opinions with respect to particular articles of faith or modes of worship.' Indeed there seems no risk in asserting that much of the jurisdiction of the ecclesiastical courts in respect to heresy, whether it shows itself in speaking, writing, or preaching, has been destroyed by the various Toleration Acts. The Criminal Law Amendment Act 1885, which abolished the jurisdiction of the ecclesiastical courts in matters of heresy, except so far as it may be directed, to prevent ministers of the Established Church from preaching in opposition to the Articles and doctrine of the establishment.
which they receive their encomiastics.' So far as this, there is certainly no objection. There ought to be some speedy mode of depriving a man of these encomiastics, which he accepts upon certain terms. He who will receive them [Franks, 9, 5] as a reward for doing what he is paid for teaching, deserves the reprobation of all mankind; and those who dislike ecclesiastical authority most could not be better pleased than to see such an offender hanged or quartered, or hanged, quartered, and burnt in any way that the rule of the church provides, to which the offender has solemnly submitted himself.

In the year 1866, proceedings were commenced in the Archdiocesan courts against the Rev. Mr. Oakley for writing, publishing, and maintaining doctrines contrary to the Articles of Religion.

The history of Heresy in England is instructive. The change from burning alive to the free expression of opinion on religious matters is one of the steps in the social progress of England. For some other matters connected with the subject, see [Blair, 4, F. C.]

HERMES, Gnomus, the founder of a philosophical school of Roman Catholic theology, was born on the 22nd of April, 1776, at Dreverwald, near Miinster in Westphalia, where he received his first education from the priest of the parish. He subsequently became a pupil at the gymnasium at Rheinau, and there gave the first proofs, especially in his mathematical lessons, of his strong mental powers. After the year 1797, when he entered the theological faculty at Miinster, he made up his mind to devote himself with great zeal to the study of the philosophy of Kant, and thus arrived at the conviction that one had better establish a perfect system of theology unless he was prepared to make the first steps in the direction of a new human knowledge. In 1798 he was appointed teacher at the gymnasium of Miinster, and his exertions henceforth were directed towards restoring, on a firm basis, that which had been demolished by Kant's 'Criticism of pure Reason.' But as a teacher at the gymnasium, he had no opportunity of making known the results of his philosophical studies. This opportunity however was offered to him in 1807, when he was appointed professor of theology at Miinster. His great talent as a lecturer, and his kind and benevolent manners, attracted great numbers of students. On one occasion, when he had to give his opinion on some ecclesiastical question, he greatly offended Droste-Vierchor, afterwards Archibishop of Cologne, and the ill feeling thus created had probably some influence in the subsequent proceedings against the doctrines and followers of Hermes. In 1810 Hermes was appointed professor of theology in the newly established University of Bonn. His lectures again attracted students not only from all parts of Catholic Germany, but the King of the Netherlands sent a large number of young men to Bonn for the purpose of studying under the professor of the highest esteem both of his colleagues and pupils. He died at Bonn on the 26th of May, 1831.

The only work that Hermes published bears the title 'Philosophical system of the Church-Catholic founded in 1819, 8vo.' A second edition appeared in 1831. So long as the Archibishop Spiegel zum Doensberg was alive, Hermes and his views were not attacked by the see of Rome; but soon after the elevation of Droste-Vierchor to the archbishopric of Cologne, reports were made to Rome about the injudicious tendency of Hermes's work, which still continued to be the chief theological manual at Bonn and other German universities, where the chairs were filled by the disciples of Hermes. There is no doubt that the denunciation against Hermes was in the first instance made by some German who was hostile to him, but it was taken up very eagerly at Rome by Pius VI. In his report to the pope on this remarkable point in Hermes's work was his principle, that reason or philosophy must in the first place prove the reality of a divine revelation, and in the second, the truth of the Roman Catholic system. These ideas being ascertainment, Hermes demanded absolute submission to revelation. He does not attempt philosophically to prove the truth of every particular dogma, but only to show that the Church has a right to establish her dogmas, and to demand submission to them. Hermes thus did not attack a single dogma of the Church, and his orthodoxy can scarcely be disputed; but if we consider that there was the greatest abuses under him, that every theologian had the right of exercising his private judgment, and at the same time remember that the Roman hierarchy had reason to dread every philosophical inquiry into its system, since, although Hermes remained orthodox, it was by no means certain that future theologians might not be led astray by their application of philosophy to theology, it will not be surprising to find that, on the 26th of September, 1835, the pope issued a brief against the work of Hermes. The severity with which this brief was received by the German people was such that the execution produced a rupture between the courts of Berlin and Rome. The disciples of Hermes made all possible efforts to defend their master, and two of them, Professors Braun and Elvenich, refusing to make the submission to their constituents of Hermes. In the same year the professors Braun and Achterfeld of Bonn, who refused to recant their Hermesian opinions, were forbidden to lecture in the university by order of the archiepiscopal consolidator, Von Grimmel, at Cologne. The number of pamphlets that have been written for and against Hermes is prodigious, and has probably contributed not a little towards the religious movement now going on among the Roman Catholics of Germany. The best exposition of the whole controversy may be found in Erlenreich's 'Der Hermesianismus und sein Rieinischer Gegner Perronne,' Bonn, 1834, 8vo.

'Horsem,' more properly Ermolai, from the Greek ippom, signifying an inhabitant of a desert, is the name given to a race of men who retired from society without becoming members of any monastic community, and the institution between hermits and monks, and the origin of both, are explained in P. C. under the term 'Monachism' (437).

HERMOGENES, a heretic of the early church, against whom Tertullian has written a treatise, was most probably a native of Africa, and polished, according to Bunsen and Le Clerc, A.D. 168. The chief information we possess respecting him is contained in Tertullian and Theodoret. It appears from the former of these writers that Hermogenes, though professedly a Christian, had throughout his life evinced a strong tendency to the Gnosticism of the Hermesians, and especially to those of the Stoics. He is accused of having taught that God made the world out of matter that was coeternal with him. The chief design of Tertullian's treatise is to confute that notion; his principal argument against him is, that if matter be eternal, there must necessarily be two Gods, which however Hermogenes did not allow, but expressly asserted the existence of one supreme governor of the universe. The following, in a few words, appears to have been the system of this heretic: he did not introduce any con or any creator different from the one God, the Father; but he asserted the eternity of matter, and the eternity of the Creator; and he taught that the universe has had a confused and turbulent motion, and to it he ascribed all the evils which exist in the creation. It was out of this confused matter that God brought order and perfection. The dogmas of Hermogenes, though strongly resembling those of the Christians, are, no doubt, the most of the other great doctrines of religion, as is not charged by either Tertullian or Theodoret with any other heresy than that to which we have alluded. We have no account of any of his writings, though it may be inferred from the arguments of his opponents that he was an author. We are ignorant of the year of his death. For a fuller detail of his opinions see Lardner, Hist. of Heretics, ch. xviii.; Tille- \lose, Hist. Eccl.; and Cave.

HERNANDIA'CÆSE, a natural order of incomplete Exogenous plants. It has monoeocous or hermaphrodite flowers, with an involucelle in the pistiliferous and hermaphrodite flowers. The flowers, which are violet, tube oblong, and possesses 5 to 7 with one and eye, is, the ovary is bilocular into the calyx in two rows, of which the outer is often sterile, with the anthers bursting longitudi- nally; the ovary superior, 5-celled, with a pendulous ovule only once. The leaf is entire, and peltate; the fruit is pendulous; the embryo is inverted, without albumen; the cotedyls somewhat lobed, shrivelled, and oily. The species are trees, which alternate entire leaves, and flowers arranged in axillary or terminal spikes or corynbe.

This order has been constituted by Blume. It contains only two genera, Hernandia and Incarpus. There are some species referred to Mc, and it appears that the absence of albumen from their seeds. Their longitudinal anthers distinguish them from the Lauraceae, in which order they have also been placed. Their affinity is undoubtedly with Thymeleaceae, from which they differ only in their dra-
HET

HEY

peculiar fruit, lobed cotyledons, and the involucre to some of the

Hernandia, the typical genus of this order, was named after

Hernandez, a naturalist sent out to Mexico by Philip II. of

Spain; and it is said to have been given to these plants, which

have some flowers, in allusion to the great opportunities

afforded to this naturalist and the little use he

made of them. The characters of this genus are the same as

the order.

Histerella is a tall erect tree, with coriaceous pellate leaves,

yellowish panicked flowers, a large inflated succulent calyx,

with a small roundish entire mouth. It is a native of the

various parts of the East and West Indies, and has obtained its

modern name from the fact that it has been cultivated

throughout its persistent involucres. The bark, the seed, and

the young leaves of this tree are slightly caustic. Rumphius

says that the fibrous roots chewed and applied to wounds

produced by the Macassar poison, act as an efficacious cure.

The juice of the leaves is employed as a depilatory. It

destroys the hair wherever it is applied, and this without

producing pain. The wood of this species is very light, and

Anstiet says that the wood of H. Gulenatns takes fire readily

from a flint and steel, and may be used as tinder. Several

species of Hernandia are mildly purgative.

Lindley, Natural System; Lindley, Fvora Medica

Buckley, Bot. Mag. 1825.

Hesperis (from 'Hesperus,' the evening), a genus of

Saponariae, as Felis is to Canis. The sweet fragrances of

the night, and hence the genus derives its name. The pods

are quadrangular, or sub-compressed, the valves keeled and

somewhat swerved, the seeds in a single row. There are only

made use of by man but as ornamental and sweet-scented plants.

II. Matronalis, Dame's Violet, is the only British species;

it has an erect branched stem, ovate lanceolate leaves,

and large handsome lilac fragrant flowers. The ladies of

Germany have pots of this plant placed in their apartments; hence

it has been called Dame's Violet. Parkinson calls it Queen's

Gilliflower; and Gerard, Damask Violet.

All these plants are to some extent noxious, and require the

same treatment as most other hardy garden-plants.

(Don, Gardner's Dictionary; Balsington, Manual.)

HETEROCERUS, a genus of pantropical coleopterous

insects established by Lesc. Latrellle places it in his

second section of his family Clanciorum, and forms it of a

tribe under the name of Aconiptopus, on account of the flat-

tened broad limbs armed with spines. These beetles have

small oval depressed bodies, and eleven jointed antennae

the last six articulations forming a cylindrical club. They

live in sand or mud, by streams or among marshes, burrowing

in the ground by means of their spinous tribe. When dis-

turbed, they wallow in the mud, and then live, like the

previous species, in the same situations with the perfect insects. Several

species are found in Britain.

Heteromera, the second section of Coleopterous insects

under the same family, comprising such as have three

five articulations in the first four tarsi, and four in the two

posterior. They are all vegetable feeders. Latreille divided

the Heteromera into four groups: 1st, the Malacoxa, dusky

or black insects, for the most part aquatic and having hard

elytra, which are often anachylos. Their jaws are furnished

with a hook, their claws are simple, and their eyes are oblong

and depressed, a character which indicates nocturnal habits.

They live in sand, or under stones, and often in cellars and

ruins. They are very tenacious of life, living many months

after being transfixed by a pin and placed in the cabinet.

Doubt exists whether these insects live in their bodies, which

much exceeds that found in allied insects, and whether they

enable them to subsist for a long period without food. They

are found in all parts of the world. The genera Pimelia, Diops,

and Tenebrion are types of many tribes among the Malacoxa.

The Diaps mortisia and the meal-worm, Tenebrion melitor,

are familiar British examples.

2nd. The Tachinies, insects without hooked jaws, with

more or less pubescent bodies, and legs adapted for running,

furnished with simple claws. They live under the bark of trees, or in the

fungi parasitical on their trunks. A few live on the ground under stones.

The genera Diops, Hippo, and Tenebrion are types of many tribes among the

Malacoxa. These insects are very injurious to crops.

3rd. The Stenolytra, which differ from the preceding in the structure

of the antennae, those organs being perforate or elevated in the Tachinies,

but simple among the insects of the present section. In other respects they are similar.

The genera Hyalus, Catopria, Omophora, Zonocerus, are types of tribes. They mostly inhabit wood. The

Dactyloa are found on flowers: they fly well.

4th. The Trachelixida, beetles having triangular or heart-shaped heads, are exclusively British, the geranium beetle

not retracted. Their bodies are soft, and furnished with wings, protected by flexible elytra. The jaws are not furni-

ished with hooks, and the claws are bifid. Lepria, Pyro-

chus, Microlepis, Horia, Lepus, etc., are genera of beetles in this division. In the tribe of Centharidn, of which

Meloe is the type, are found the blistering beetles, which were probably the insects known to the ancients under the

name of Dysidiae, and were used as a cure against the

變. This genus belongs to the natural order Scaritacceae, and consists of about

sixteen species. It has a permanent 5-cleft calyx with an imbricated stylet; undivided somewhat unequal petals;

5 stamens; 2 styles, very long, distinct, the length of the

stamens, eventually diverging; the capsule crowned by the

withered flower, at the lower part united to the calyx, 1-celled,

dehiscing between the styles. The species are herbs with leafless stems, radical leaves, and racemose or panellated flowers.

II. Americans, a genus of insects belonging to the natural

order Scaritacceae, has, in addition to the

following species, a large number of species, which

are parasitic on the sperms of plants,

and the whole plant pubescent; the leaves on long petioles, somewhat 5-lobed, toothed; the inflorascence elongated,

toothed; the bracteoles lanceolate the length of the calyx; the stamens usually

exserted. This plant is a native of North America, where it has

obtained, on account of its astringent properties, the name of Acanthus Root. The stamens are united in pairs, and

its astringent character is to be ascribed. The other

species contain tannin, but are not used for any purpose in

the arts or medicine.

(Don, Gardner's Dictionary; Lindley, Flora Medica.

HEXAPLA, the plural of Hexaplos, which means 'six fold,'

was an edition of the Scriptures of the Old Testament

prepared by Origen, which exhibited, in addition to the original

Greek text, a Hebrew version, at the same time giving the

seven new names for the Hebrew and Greek versions;

names of the Septuagint, that of Aquila, that of Symmachus,

that of Theodotion, one found at Jericho, and one found at

to the books of the Hebrew Scriptures.

It also comprehended a seventh version of the Psalms. The Hebrew text

was besides given both in Hebrew and in Greek characters; so

that properly speaking there were eight columns in all, whence

the work is sometimes called Origen's Octataxia.

The Hexapla, which was prepared by Origen, was introduced for

the first time into the at the Milan Synod in the year 426,

and the work was now of great rarity, many fragments of the Hexapla had been

collected by Petrus Morinus Parisiensis, and inserted by

Flaminius Nobilis in his Greek Bible printed at Rome in

1687; and all that had been recovered were given by

Joannes Drausius in his 'Veterum Interpretum Graecorum

Fragmenta,' Anhime, 1622.

(See F. C. Aquila, ii. 206; Bible, i. 372; Septuagint,

xxi. 357; Symmachus, xxii. 445; Theodotion, xxi. 286.)

HEYWOOD, JOHN, one of our earliest dramatic writers, was

lived in the first half of the sixteenth century. He was prob-

ably a native of Lincoln, was educated at Lincoln and

possession of land at North Mins, in Berks, where he is regarded

as having made the acquaintance of his neighbour Sir Thomas

More. This lover of wit introduced him at the court of

Henry VIII., where his musical skill as a performer on the

viols, and his liveliness, both in society and in his writings,

gained him high favour. To Queen Mary he was further

recommended by his zealous attachment to the Roman

Catholic Church. In the time of Elizabeth, he was engaged

in plotting against the government, and is said to have with

difficulty escaped the halter. He retired to the continent,

and died about 1565, at Mechlin, in Brabant. Heywood's dra-

matic pieces stand between the miracle plays on the one hand, and the elaborated dramas on the other.

They may properly and strictly," says Mr. Collier, in his

'History of Dramatic Poetry,' 'be called Interludes—a spec.
H I G H

G O L

cles of writing of which he has a claim to be considered the inventor. The earliest of them, 'A Merry Play between the Pardoner and the Fyee, the Curate and Neybour Pratte,' was not, however, but was written before 1521. In Doddale's "Old Plays" will be found his 'Play called the Foure P.F., a new and a very merry Entertlude of a Palmer, a Pardoner, a Pottery, a Pedlar,' which is a fair specimen of the metrical arrangements and of the grotesque coarseness of his humour, and other productions bearing his name was a posthumous volume of 'Woorces,' 1578; 4to., which contains proverbs in verse, and six hundred epigrams, by which in his own time he was probably not best known. In respect of them, and to distinguish him from a later play-writer [HITWOOD, THOMAS, P.C.], he is not unfruitfully called 'The Epigrammatist.'

The genus of plants being a part of the natural order Compositae. The heads are many-flowered, the involucres imbricated with many oblong scales. Fruit terete, angular, and furrowed, with a very short crenulated margin. There are nineteen British species of this genus, but none of them are valuable on account of the properties they possess. 

H. Pilosella has a leafless single-headed stem; diplocanecule or lanceolate leaves, hairy above, glabrous beneath. The flowers are of a pale lemon colour with a red streak on the back. It is found on dry banks and elevated places. H. alpinum has lanceolate leaves narrowed into a footstalk, entire or toothed; the involucre is covered with long silky hairs externally and suffused with a bright yellow colour. It is found on rocks in Great Britain. (Babington, Manual of British Botany.)

HEROCLOE, a genus of grasses belonging to the Phlox family, consists of species with leaves alternately arranged, 3-angled, about as long as the flowers; three flowers, the lower with three stamens, the upper palea with two keels, the upper flowers with both stamens and pistils, the stamens two, the upper palea with 1 keel. The species of this genus, the H. berolina, has been found in Great Britain: it has an erect panicle, glabrous pedicles, and flowers without awns. The stem is about a foot high. It has only been found in Scotland. (Babington, Manual of British Botany.)

HIGH COMMISSION COURT, a tribunal established by Queen Elizabeth under the authority of a clause in the Supremacy Act (1 Eliz. c. 1), which exercised arbitrary power in matters of faith and in ecclesiastical concerns as the Star Chamber did in civil affairs. The commissioners were forty-four in number, of whom twelve were ecclesiastics, and three commissioners constituted a quorum. Their jurisdiction extended over the whole of the kingdom, and was not confined to the clergy, but included all classes. They were directed to visit, visit, reform, correct, and amend all errors, heresies, schisms, abuses, offences, contempt, and enormities whereby any ecclesiastical or any other authority whatsoever might be lawfully ordered or corrected. The commissioners, or any three of them, judged at their own discretion any speech or writing which tended to heresy or schism. All appeals to prior ecclesiastical jurisdictions were determined before the Court of High Commission. The court was empowered to punish incests, adulteries, fornications, and to inquire into matters relating to matrimonial offences. Other ecclesiastical courts had been subject since the Reformation to inhibitions from the supreme courts of law, but this court was exempt. It exercised its powers therefore without control, and was authorised to conduct its proceedings, not only by the ordinary legal processes, by juries and witnesses, but to use all other means and ways which they could devise. This empowered them to resort to the rack, to torture, inquisition, and imprisonment, and to proceed, not upon information, but at their own discretion upon rumour and suspicion. The court could bring before it a suspected person, and by administering to him an oath, compel him to answer any question, and thereby criminate himself or his friends. Refusal to take this oath was punishable by imprisonment. Fines were levied which often ruined the offender, and he might be imprisoned for any length of time at the discretion of the court. The great object for which the court was established was more especially the propagation of the doctrine of Uniformity in matters of religion or in the services and ceremonies of the Established Church. Elizabeth, in a letter to the Archbishop of Canterbury, said she was resolved 'that no man should be suffered to hold a preaching on the left hand, or on the right hand, from the drawn line limited by authority and by her laws and injunctions.' The Commons remonstrated boldly against the tyranny of the Court of High Commission, and by way of answer she granted towards the close of her reign a new patent in which the powers of the court were in some respects extended.

In the reign of James I., the sentences of the Court of High Commission were most generally confined to deprivation; but when the Commons remonstrated on account of its proceedings he refused to interfere. In 1610, by virtue of the royal prerogative, he established a Court of High Commission in Scotland, the authority of which was readily acknowledged by the bishops and some of the clergy.

In 1641, the Court of High Commission and the Star Chamber were both dissolved, and a clause was introduced into the act which prohibited the revival of the former court or any other of a like nature. James II., however, issued a new commission, and appointed seven commissioners to execute the powers and arrangements under the former courts, and with the full powers of the former courts. Serneoot, archbishop of Canterbury, refused to be a member. Four of the commissioners were bishops, and the three laymen were the Earl of Rochester, Chancellor Jeffries, and Lord Chief Justice Herbert. The Revolution swept away this arbitrary institution.

HIGH COURT. — [Constable, P. C., p. 486.]
HIGH STEWARD. [Steward, Lord Hugh, P. C.]
HIGH TREASON. [Steward, P. C.; Law, Criminal. P. C. S.]
HIGHMORE, JOSEPH, a portrait and historical painter of some reputation in his day; was born in London in 1692. He was the nephew of Highmore, Surgeon-painter to William III., and was originally bred to the law, but having a decided disposition for painting, he gave up the law and became a pupil of John Faber, and was afterwards a pupil of Sir Godfrey Kneller, and of Sir Peter Lely, and subsequently became a pupil of Sir Charles Dughet. He was for some time resident in Paris, and on his return to England lived in Lincoln's Inn Fields, where he painted a set of portraits of the Knights of the order of the Bath, which has been engraved by John Pine. Highmore was a man of much general information; he had a good knowledge of anatomy and was thoroughly acquainted with perspective. He used to attend Chesheden's lectures, and he made the drawings for his treatise on anatomy: we owe to him also one of the best practical books on perspective:—'The Practice of Perspective, on the principles of Dr. Brook Taylor; in a series of Examples, from the most simple and easy to the most complicated and difficult cases,' London, 1769. He published also a critical examination of the ceiling painted by Rubens, in the Banqueting-House at Whitehall; it represents the apotheosis of James I. Highmore painted many portraits of royalty, nobility, and gentry, one of the best of which is that of Young, the poet, at all Souls' College, Oxford. His historical pieces are of only average merit; one of the best, Hagar and Ishmael, was presented by him to the Foundling Hospital, London, 1702; there is also in the same institution a portrait of Mr. Emerson by him. He painted several pictures from the works of Richardson the novelist, but his chief works are taken from the Scriptures. He died at Canterbury. He was married twice; he first was married to one of the prebendaries of that city, and he was buried in the cathedral. (Gentleman's Magazine, April, 1780.)

HIGHTEA, a genus of fowli plants from the Isle of Sheppey. (Bowerbank.)

HILLIARD, NICHOLAS, limner, painter, and goldsmith to Queen Elizabeth and to James I., was born at Exeter in 1547; his father, Richard Hilliard, was high sheriff of Exeter and Devonshire in 1560. Hilliard, a limner by education, acquired painting by studying the works of Holbein, and he obtained great celebrity as a miniature painter. Dr. Prout, in his poem on the storm in which the Earl of Essex was surprised, returning from the island voyage, says—

Hand and hand of
By Hilliard drawn, a worth a history
By a worse painter made.

There are many miniatures, especially of ladies, by Hilliard extant. He painted Mary Queen of Scots several times, James I., and Prince Henry. He had for twelve years the exclusive privilege of painting and engraving the portraits of James I. and the royal family. Charles I. possessed a large number of his works, and also of those of the Spanish Armada, and a curious jewel containing the portraits of Henry VII., Henry VIII., Edward VI., and Queen Mary; on the top was an enamelled representation of the battle of Bosworth, and on the reverse the red and white roses.

By hand of
By Hilliard drawn, A worth a history
By a worse painter made.
HILTON was the master of Isaac Oliver: he died in 1619, and was buried in St. Martin-in-the-Fields.

(Wallpole, Anecdotes of Painting, &c.)

In 1806, his son, Henry Hilton, abbot of Lincoln, was elected to the See of Lincoln on the 3rd of June, 1786. His father, who was a portrait painter and a native of Newark, died in 1822. Hilton was placed with J. R. Smith, the engraver, in London, in 1800; he obtained a scholarship by the Royal Academy as a student, and in 1808 he exhibited at the Academy — a picture of 'Buddhist, in a good style, and of extraordinary merit for so young a man.' In 1804 he exhibited his picture of 'Hilton receiving the Blessing,' which was generally well received, and praised in the 'Critical Review' and 'Procris.' These early works were followed by a series of noble compositions, in a superior style of execution and treatment, which greatly distinguished him from the majority of his other laborers. However, neither his subjects nor his style were popular, and he had the mortification to witness the success of very inferior artists, while his own works remained on his hands.

In 1814 he exhibited Miranda and Ferdinand bearing a Log; and he was elected an Associate of the Academy in the same year. He was elected a member in 1820, when he exhibited his picture of 'Gannymede, which he presented to the Academy as his diploma piece. In 1822 he exhibited his Christ crowned with Thorns. Two years afterwards he succeeded Fuseli as keeper of the Academy, a post which he held until his death on the 30th of December, 1839, in his fifty-fifth year.

Hilton died in possession of his best pictures — The Angel releasing St. Peter from Prison; Serena rescued by Sir Calepinus; Comus; the Murder of the Innocents, exhibited in 1822; the Death of Abel, exhibited in 1832; Una with the Lion entering Corecen's cave; and Rizaph holding the dead bodies of Saul's Sons (unfinished). Sir Calepinus rescuing Serena, exhibited in 1831, was purchased by the subscription for Hilton's 'excesses, for 500 guineas, and was presented to the National Gallery, where it now hangs, and is one of the most attractive English pictures in the collection, though far from being the best of Hilton's works. Una entering the Cave of Corecen, exhibited in 1832, was purchased by R. Elison, Esq., and was engraved by W. H. Wett for the Art Union of London, and distributed among the subscribers of 1842. St. Peter delivered out of Prison by the Angel, of which the figures are of the size of life, also exhibited in 1831, was purchased by William Bishop of Plymouth. Mr. Robert Vernon, who possesses the best collection of recent English paintings extant, has two capital works by Hilton — Rebecca with Abraham's servant at the Well, exhibited in 1829; and Edith and the Monks searching for the body of Harold, exhibited in 1834. The following also appear to have been executed by the same hand — Hanging Bilibies, in the possession of Sir John Swinburne, Bart.; Jacob parting from Benjamin, in the possession of W. Wells, Esq.; the Graces teaching Cupid to play on the Lyre, the property of Sir James Phillips, Bart.; Cupid sitting on a Quiver, belonging to W. Smith, Esq.; Cupid and a Nymph, the property of J. II. Turner, Esq.; the Rape of Europa, painted for the late Earl of Egress, of which there is a print by Charles Heath; and the Infant Warrior — "This Hoppy Man is washing clothes; his infant warrior." (Secundus, exhibition in 1836.)

The greater part of the above-mentioned works were exhibited with the works of old masters at the British Institution in 1840. Hilton must ever rank very high among the painters of his own country, his own style, which appeared at a time when the sphere of comparison is extended. He was not a great painter; his energy was not extraordinary, nor was his invention exuberant, but his colouring is harmonious and rich, and his taste in composition and design was refined and masterly. The figure of Sir Calepinus, in the National Gallery, is not a very good specimen of his style; it is exaggerated, and is not upon its feet. This is a peculiarity which occurs more than once in Hilton's work. But his figures sometimes show the falling out of his specific gravity. Those who knew him describe him as a man of much intelligence and great amiability. 'His manners were mild and graceful; his voice was at all times low, and his manner, even in conversation, mild and unassuming.' He died a widower, and childless.

HINCMAR was born in France in 806. He was of a noble family, and nearly related to Bernard, Count of Tou- lose. At a very early age he was placed under the care of the abbot of St. Denis, in Paris, and in 810, when he was seen to have acquired a high reputation for learning and strict observation of monastic discipline. His talents and high birth brought him under the notice of the Emperor Louis the Moek, at whose court he frequently appeared; and whose court he was afterwards to frequent at the request of his orders. He must have had a high opinion of himself, for, in having under the displeasure of his royal master, he was banished from the court, and retired to Saxonzi, where he was accompanied by Hincmar. On the death of Hilton, his successor Lewis was a man of grave integrity, of great probity. He again introduced him to the court of the emperor, who presented him with the government of the abbots of Notre Dame at Compiegne and St. Germer. On this occasion he entered in his respect for the observance of the canon law, which at that period was often set aside, in requesting the sanction of the bishop of the diocese, and that of his own abbey, previous to accepting that prebend. In the year 845 was assembled the first council of Beauvais, consisting of ten bishops of the provinces of Rhinns and Sens. In that council the deposition of Ebbonius, archbishop of Rhoins, was confirmed, and Hincmar was elected by the clergy and people to succeed him. The following year, the council of Sens, under the presidency of Hincmar and the primate of Sens and Bourges, in which the powers of the metropolitan bishops were more clearly defined and extended.

About this period Godescalclus, a native of Germany, and monk of Orbais in France, attracted popular notoriety by a new exposition of the doctrines of St. Augustine on predestination. His peculiar views on this abstruse subject were prominently brought forward during a pilgrimage which he made to Rome, and drew upon him the displeasure of the principal theologians of the day. A council was convened at Mayence by Raban Maurus, archbishop of that city, in which the opinions of Godescalclus were combated and condemned, the arguments against him being chiefly deduced from the writings of St. Au- gustine himself. It was then resolved to transmit his case, and to leave the judgment to be pronounced upon him to Hincmar, in whose province was situated the monastery of Orbais. The peculiar opinions of this imprudent monk, magnified by the hostile interpretation of them which Raban brought to Hincmar, had been brought forward to him from one who had already begun to rule the church with an iron hand. Hincmar caused him to be accused before thirteen bishops at the council of Quiercy, where he was declared an incorrigible heretic, and deposed from the ecclesiastical functions to which, it appears, he had been irregularly admitted. This punishment, however, was not sufficient to appease the rancour of his judges; the bold enunciation of his tenets was construed into contempt, and, as such, punishable, according to the rule of St. Benedict, by corporal chastisement. He was condemned to a public flagellation, and to commit his writings to the flames, which sentence was executed with all the cruelty so characteristic of that barbarous period. He was afterwards confined in the monastery of Hautvilliers, where, twenty years afterwards, he ended his miserable existence.

In the year 852 Hincmar embellished and enlarged the church of St. Benoist, and caused several works to be constructed, in which he deposited the relics of its patron saint. The following year he assisted at the council of Soissons, in which all the ministerial acts of his predecessor Ebbonius were declared to be void, the sole exception of Beau-

HIN -
subject of Predestination, which has been preserved. The arguments in it are chiefly directed against the opinions of the learned John Scotus Eriugena, whom he accuses of error respecting the Trinity and its presence in the eucharist. Among other curious accusations brought against Scotus, he charges him with believing that the soul of man is not lodged in the body, and that the body consists only in remorse of conscience caused by the remembrance of sins.

In the year 862 we find Hincmar engaged in controversy with the pope, Nicholas I., one of the most learned ecclesiastics of his time. The occasion of this controversy was the assumption of power by Rothadis, bishop of Soissons, who incurred the displeasure of his metropolitan, Hincmar, on account of the deposition of a priest of his church, whom Hincmar wished to restore to office. Rothadis, refusing to re-admit this priest, was condemned in two councils held at Soissons, excommunicated, and afterwards deposed and imprisoned. On an appeal of Rothadis to Rome, the pope issued a peremptory order to Hincmar to restore this bishop to his see within thirty days, or to appear at Rome, either in person or by legate, to answer the charge which had been made against him. In the year following Hincmar commissioned Odo, bishop of Beauvais, to proceed to Rome, and to request a confirmation of the decree of the council of Soissons. Nicholas, irritated at the opposition of Hincmar, rescinded the decisions of that council, and demanded the libration of Rothadis, in order that he might hold a session at Rome in justification of his appeal. This demand was at first resisted by Hincmar, but, through the interference of the king, Rothadis was released, and deputies were finally sent by Hincmar to the pope to state the case of the bishop. This truce was soon followed by one more important; Rothadis was restored to the episcopal dignity, and he returned to his diocese accompanied by a legate of the pope. The pretensions of Rome to this effect are more fundamentally based on the Ancient Pontiffs, a work probably composed by Isidore Mercator, but claiming much greater antiquity. Hincmar, though the most learned pontiff of the age, does not appear to have disputed the authenticity of these documents.

The interference of the Pope in temporal matters was however more successfully resisted. On the death of Lothaire, king of Lorraine, Adrian II. was desirous of excluding Charles the Bald from the succession of his states, and to bestow them upon the Emperor Lewis. To this effect he addressed two letters, one to the nobles of Lorraine, and the other to the subjects of Charles, threatening excommunication should they disobey his injunctions to favour the cause of Lewis. Hincmar, in the name of his fellow subjects, replied to the pretensions of the Pope. In his letter he remarks that Adrian II. had in mind that he is not at the same time king and bishop, and so he did not dare to undertake the conduct of the church, which was their concern, not the state, which is the heritage of kings. The opposition was successful, and Charles the Bald and Hincmar together, took possession of the throne of Lorraine, and the pope, who had set on foot these operations, was left to bear the consequences of his attempt.

In the year 871 Hincmar proroged at the Council of Douai, composed of twenty bishops assembled by the order of Charles the Bald, for the purpose of inquiring into the conduct of Hincmar, bishop of Lonnep, nephew of the archbishop of Rheims. He was accused of spoliation of church revenues, of usurpation of powers not properly belonging to a bishop [INTERDICTION, P.C.J.], and of revolt against his sovereign. His uncle appears to have conducted the trial with severity impartially, and, as he was no bishop, he was dismissed from degrading from his ecclesiastical office.

About ten years after these events Hincmar exercised the same firmness in defending the rights of the church against the interference of the secular authority. It is not surprising that he had shown no disposition to parent or dispose of the claims of the Roman pontiff. Lewis III. wished to bestow the bishopric of Beauvais upon Odacer, a favourite courtier, who had been rejected as unworthy of the office by the ecclesiastical authority, and he endeavoured, by application and menace, to obtain the acquiescence of Hincmar to his nomination. This prelate, however, boldly defended the liberty of canonical elections, and the independence of the church. The pope pressed him to resign, and he finally renounced the ecclesiastical charge of the see of his country; he had taken to the respect the privilege which the church possesses to refuse induction to unworthy candidates, and warns him against arrogating to himself a power which had been denied to the most eminent of his predecessors. 'I trust,' he observes in it, 'ever to preserve inviolate my fidelity and devotedness to your service, indeed I have not a little contributed to your own election; but I must return to the charge, that it is my religious duty and my profession made me in my old age to depart from the holy rules of the church, which, thanks be rendered to God, have ever been my pride during six and thirty years of my episcopacy.' (Hincm. epist. c. 871, p. 188.) He prudently renounced in remorse of conscience caused by the remembrance of sins.

Hincmar did not however long survive his royal master; about this period the Normans extended their predatory incursions as far as his province, the principal towns of which were pillaged and destroyed. They were advancing towards Rheims, when notice of their approach was given to Hincmar, who was obliged to leave the city by night, having previously taken the precaution to secure the treasures of the church, and the relics of St. Remy. The aged prelate arrived at Epernay, worn down by fatigue and anxiety. Severe illness compelled him to remain in that town, where, on the 21st of December, 877, he died. The death of Hincmar has been associated with the darkest period of ecclesiastical history, will ever be conspicuous as that of one of the most zealous defenders of the liberties of the church. His firmness and integrity in his views, which could alone present an effectual barrier against the encroachments of regal and papal authority. The memorable words which he uttered when he heard that the Pope was about to visit France, and that the excommunication, of his bishops, are a sufficient index of his fearless spirit. 'Si excommunicatus venit, excommunicatus abit,' if he comes to excommunicate, he will return excommunicated.'

The following is a summary of the article, 1st, 'A Treatise on the Duties of a King,' addressed to Charles the Bald. 2nd, 'On the Ordal by Water,' which practice he attempts to authorize by quotations from Scripture, and which unfortunately proves that he was not superior to the superstitions of the age. 3rd, 'On the Rights of Metropolitan Bishops.' 4th, 'On the Translation of Bishops and on their Duties.' 5th, 'On the Council of Nice;' and 6th, 'On the Nature and Sanity of Oaths;' besides several letters and 'Capitalaria.' His works have been collected in two volumes by the learned Simmond, Paris, 1645, and another volume was added to this collection by Canisius, Leipsic, 1669.

The following are his principal writings which have been consulted, and may be referred to for a fuller detail of his life: Fleury, M. de Molaise, and Waddington's Ecclesiastical History. Lect. IV. of Waddington's History of the Church of France. Mâssard, Hist. de France, vol. ii.; Mallet, Hist. de France, vol. ii.; and Guizot's Sixth Lecture on Modern Civilization.

HINDOO ARCHITECTURE. [Hindustan, P. C., p. 235.]

HINGE, a kind of joint, usually made of iron or brass, upon which doors, gates, shutters, box-covers, &c., are made to turn in the act of opening and shutting. Hinges are constructed in a great variety of forms; but in most of the commoner kinds the section is that of a hollow cylinder working round a fixed central pin. Without pretending to describe or illustrate these various forms, it may be stated that few of the more important deviations from the ordinary form, referring to Hebert's 'Engineer's and Mechanic's Encyclopaedia' for fuller details. In Collingue's patent hinges, which are peculiar because the principal rubbing is at the principal rubbing is between a hollow cap and an accurately turned sphere, formed, as it were, upon the end of the pin; a cavity being provided for the reception of a piece of lead or paste, to prevent its rattling. The hinge, which is pin, another celebrated manufacturer, who has displayed his ingenuity especially in designing hinges for unusual and apparently insuperable situations, in rendering their ornamental and effectual. There exists a hinge for doors that will prevent disfigurement, and for contriving invisible hinges for situations in which it is desirable to conceal the hinges altogether, is the inventor of the sliding hinge so frequently used for hanging room-doors in houses of superior character.
In ordinary door-hinges the hollow cylinder which works round the axis or central pin is divided transversely into two, three, or more portions: one or more of such portions being attached to and forming part of that leaf or half of the hinge which has acquired the character of the door. These portions form part of that half of the hinge which is screwed to the door-post. In the rising hinges a similar arrangement is followed; but instead of the hollow cylinders being divided transversely into right angles, they are divided by spiral or rather helical lines. The result of this contrivance is, that when the door is opened it is lifted up a little from the floor by the sliding upon one another of the inclined surfaces of the leaves. In this, as they are very close to the floor, it rises, when opened, to a sufficient height above the floor to allow its lower edge to clear the carpet. Another advantage of this kind of hinge is, that the weight of the door acting upon the inclined rubbing surfaces of the hinges, causes it gently to close itself so soon as the hand is removed from it; but as this might in some cases prove inconvenient, it is usual to cut a portion of the hollow curves away, so as to form two horizontal planes which come opposite to each other when the door is opened to about an angle of 90°, or so as to form a right angle with its position when shut. By this arrangement the door retains its disposition even when the door is kept open to a great extent, which is as much movement as is usual upon a person entering or leaving the room, but will stand open if opened or beyond 90°, although even then a very slight push is sufficient to shut it. When the door is kept open in a small spring is attached to hinges of this description, to aid the closing of the door when it has been opened but a little way. In connection with such spring hinges, small spring plates are used for the doors of public offices, when it is desired to render the closing of the door both certain and quick. For such doors, hinges which open in either direction and cause the door to spring back to its original position are often used. In connection with such spring hinges, we may notice Hebert's contrivance of a hinge for external shutters, in which a spring catch or detent is employed to hold the shutter open, the catch being readily serviceable to release the catch before the shutter can be closed.

One of the most curious contrivances of the hinge kind is that which Hebert describes as Whitechurch's patent hinge, the details of which are too complicated to be explained without several illustrations. We can only state that it is an apparatus by which doors or windows may be opened at pleasure either on the right or left hand, or by which, in other words, either edge of the door may be made, at pleasure, the opening edge. A handle is fixed near to each side of the door or window, by turning which the required positions of the apparatus are varied at pleasure: the action of the hinges is all the contrary to the common kind of hinge; a style or post near to which it is placed, and at the same moment to complete its hinge-like connection with the opposite style. Notwithstanding the singularity of this action, the device is so simple and so entirely obvious in its import, and capable of turning upon its hinges with greater facility than one hand in the common way; and it cannot be understood without examination, but requiring the attention of the user. Such a mode of hanging doors is recommended for cabins in ships and steam-vessels, and for other situations in which space is very limited and great convenience is required.

Another contrivance worthy of notice, which is also described and represented by Hebert, is Nettledoff's hinge for the doors of book-cases, by which two adjacent doors opening in contrary directions may be hung without an intervening step: the two doors being divided together by a hinge resembling that by which ordinary doors are hung, and the axis of this hinge being connected with the edge of a thin partition in the book-case by metal brackets above and below the hinge, the space occupied by which is notched or cut out of the edges of the doors. Doors hung in this way fold completely back, and the hinges do not offer the slightest impediment to the removal of the volumes which happen to stand next to the partition, and which, were the doors hung in the usual way, could only be removed by first taking out those which stand adjacent to them.

HIPPOPHAE (from Πηγος a horse, and φωσ, food), a genus of plants belonging to the natural order Leguminosea. It has the limb of the calyx 5-parted with linear segments; the tube of the corolla long, straight, entire; with the limb 5-parted nearly of the same length as the tube; the petals and calyx more or less monadelphous and symgenous; the stigma stellate, the capsule 2-celled, 2-valved, many-seeded. H. longiflora is an herbaceous plant, with short axillary pedicels, mucronate or coarse toothed leaves, with long slender white flowers. It is a native of Jamaica, St. Domingo, Cuba, and Martinique, in damp places and by the side of streams. This is one of the most poisonous of plants. If the juice only accidentally touches the lips or eyes it produces a burning inflammation. Horses are violently purged after eating it.

(Hon. Gardener's Dictionary; Lindley, Flora Medica.)

HIPPOCREPIS (from Πηγος a horse, and σπειρινος, a wheel, on account of the curved shape of its pods), a genus of plants belonging to the natural order Leguminosea, the tribe Hedy- sareae. It has diadelphous stamens, a piliferous scotic style; the legume curved, with numerous 1-seeded joints; the seeds cylindrical or compressed, obtog, curved, fixed to the middle part of the joint, and therefore the umbilicus is in the middle of the curve. The species are herbs, or under-shrubs, with unequally pinnate leaves and yellow flowers, which are sometimes solitary and axillary, sometimes seetle, but usually disposed in umbels on the tops of the axillary peduncles. H. Eulaleocentron, a shrub from Minorca, is a shrubby erect plant, with the peduncles longer than the leaves, bearing an umbel of flowers at the apex, the legumes glabrous, a little arched. It is a native of the island of Minorca. It is a pretty plant, which may be kept in a flower pot and brought into the house in winter. It grows well in a soft composed of loam and peat; and cuttings strike readily under a hand-glass.

H. comosa, which grows in Italy, has umbels unumbel- late, their joints rough, curved, neither dilated nor bordered, glabrous; the peduncles longer than the leaves. It is a native of Europe, and is found on dry chalky banks in Great Britain. It is also found in the north of Austria, and in

There are seven or eight more species of Horse-shoe Vetch, They are all worth cultivation on account of their beauty. The perennial species are adapted for rockwork and banks, and are propagated by dividing the roots. The annual species should be grown from seeds, which may be sown early in spring.

Hon. Gardener's Dictionary; Babington, Manual of Brit- ish Botany.)

HIPPOPHAE, a genus of plants belonging to the natural order Leguminosea. It has discolored flowers with ovate sepals. The staminal flowers have a perianth of two leaves adhering by their points; the stamens have four very short filaments; the pistilliferous flowers have the perigonium tubular and cloven at the summit; the style is short, the stigma elongated; the nut 1-seeded, clothed with the large covered berry-like fruit. The fruits are sweet and

The only species of this genus is the H. rhamnoides, which is a small shrub found on the east and southeast coasts of Great Britain, and other parts of Europe. The said berries yielded by this plant are often eaten as a fruit, and are in this

HOA

The Yellow Sea, is a large Mediterranean sea, which runs into the eastern coast of Asia, being enclosed on the west and north by China Proper, and on the east by the peninsula of Corea; on the south it is open into the Pacific Ocean. The Gulf of Bothnia contains the Gulf of Bothnia est them with their fish.

Babington, Henry, ALOYSIUS, was born at Alcobi near Donnrueschleir, Baden, June 27, 1759. In early life he visited Italy and studied the remains of classic art there, and on his return settled at Berlin, having been appointed preceptor to Prince Henry of Prussia. In 1790 he became professor of architecture and the fine arts at the academy of Berlin, and was subsequently made professor of archaeology at the University of Berlin. Among his numerous publications are several special disquisitions on particular structures, such as the Temple of Solomon, the Temple of Diana at Ephesus, and the Pyramids of Egypt; but those by which he will be most generally and longest known are his Bau- kunst nach den Grundstimm der Alten, 1821-7, 8 vols. 4to., with a folio atlas of plates. This last not only gives a history of ancient architecture, that of Egypt included, down to the time of the Renaissance, but also a full account of all the various classes of buildings. Letterly he was much occupied in arranging the collections in the Berlin Museum, which brought him into a literary dispute with his former pupil and competitor, who was to have visited the country and made remarks on English art. Hirt died at Berlin June 29, 1837, just two days after entering his seventy-eighth year.

Hoadley, Benjamin, M.D., eldest son of Bishop Hoadley [HOADELY, B. BAXAND, P. C.], was born February 10, 1765, in London. He was admitted of Corpus Christi College, Cambridge, April 8, 1782, and received his degree of M.D. in 1792. In 1789, he was appointed physician to his Majesty's household, and in January, 1790, was appointed physician to the household of Frederick, Prince of Wales, and he held both offices at the same time. He was the author of 'Three Letters on the Organs of Respiration,' read before the Academy of Physicianians in London, 1785, and the Gulstonian Lectures for that year; 'Oratio Anniversaria in Theatro Col. Medico, ex Harvoi instituta, habita die 18o Nov. 1742,' and the Observations on a Series of Elec- tric Phenomena, 1756, 4to. He was also the earliest of the family to be distinguished for his performance of the character of Ranger, in the dramatic pieces. Dr. Hoadley died August 10, 1757, in his house at Chelsea. His brother, the Rev. John Hoadley, L.L.D., born October 8, 1771, died May 17, 1810, was also with the family.

Hoadley died August 10, 1757, in his house at Chelsea. His brother, the Rev. John Hoadley, L.L.D., born October 8, 1771, died May 17, 1810, was also with the family.

The Yellow Sea, or that part of the Yellow Sea, which lies south of a line drawn from the most north-east corner of the Gulf of Shan-tong to the coast of Corea at the back of James Hall's Island, is at its southern extremity the mouth of the river. The Yellow Sea has the south-west coast of Corea nearly seventy miles wide, but grows narrower as it proceeds north, being near its northern boundary, barely more than two hundred miles across. The shores of this part of

the Hoang-hai are high and rocky, with the exception of a tract of about sixty miles contiguous to the mouth of the Hoang-ho on the north, where the country consists of alluvium. In the west, the valley of the Hoang-ho would be again left on high ground advance to the coast, and in this part some harbours of considerable extent are said to exist, but they have not yet been visited by Europeans. The navigation along the coast of Corea is said to be so far, at least, as the mouth of the Hoang-ho and Yang-tse-kiang the sea is full of shallows and sandbanks. On the opposite side, the coasts of Corea, the sea to the distance of fifty or sixty miles from the coast is said to be very shallow, and which are generally small. Though the number of islands renders the navigation dangerous, and requires great caution on the part of seamen, they contain numerous excellent harbours. The straits which separate the islands are generally from one mile to two, or three, or even four miles across, and are close harbours, capable of containing in security all the navies of the world. They form, in fact, an almost endless chain of harbours communicating with each other. They appear to be all inhabited, and therefore must possess fresh water.

Though the Yellow Sea is not visited by European vessels, navigation is very active, as it washes those parts of China Proper which are most populous and best cultivated, and where the manufacturing industry is carried to the highest point. Accordingly the number of junks which are not only employed in the inland fisheries, but also transport between the great eastern and western settlements, and sometimes excites the surprise of European navigators; but as the coast of Corea these vessels are rarely met with.

HODGES, men., the Family of Corea, in the Life of Lord Dartmouth. In 1776, he made a visit to China, and produced a series of his letters to the Royal Society; and also a Letter on his Voyage to the Yellow Sea; and his ital Hall, Account of a Voyage of Discovery to the West Coast of Corea, etc.

HOARE, WILLIAM, R.A., an historical and portrait painter, born at Bath about the year 1706. He studied at Rome nine years, where he was the fellow pupil of Pompeo Batoni, under Francesco Penni, called D’Imperio. Upon his return to England he established himself at his native place, where he acquired a great reputation as a portrait painter in oils and engravings; he painted also some historical pieces. There is an all-slate piece by Hoare, of Christ bearing the Cross, in the church of St. Michael at Bath; and another of the Lane Man healed at the Pool of Bethesda, in the Octagon Chapel, for which he received 100L. and a pew in the chapel. He was one of the original members of the Royal Academy, and sent several works to its early exhibitions. He died at Bath in 1792.

HOARE, PRINCE, who succeeded Boswell as foreign secretary to the state, and was the eldest son of William Hoare: he was professionally a painter, and is known as the author of about twenty dramatic pieces, among which are—No Song nor Supper; ‘Lock and Key’; My Countryman; and an opus major, entitled As a man, 1806, ‘An Inquiry into the requisite cultivation and present state of the Arts of Design in England,’ 8vo. p. 270.

Prince Hoare presented the so-called ‘Slaughter of the Innocents’ to the Foundling Hospital, which institution has lent it to the National Gallery; it is however only a part of a composition, and has been so completely punished and vandalized over, that if originally by Raphael, now at least nothing whatever of Raphael remains but the composition, which is brutal and without expression. Prince Hoare died at Brighton in 1834, aged eighty.

HOARE, SIR RICHARD COLD, Baronet, the artist of Wiltsihi, and an eminent biographer and antiquary, was born the 9th of December, 1758, and died the 19th of May, 1836. His father, the first baronet, was married to Anne, second daughter of Henry Hoare, Esq., and of Susanna, daughter and heiress of Stephen Colt, Esq. In a very pleasing autobiography which Sir R. C. Hoare drew up in his old age, he says:—‘In my youth I was initiated in the business of our family bank (Hoares’ bank, Fleet-street, London), till my grand father removed me from it, and gave me to use during his life-time all his landed property. An early habit of painting led me to purchase, at the age of seventeen, a pen and pencil; for, without some amusement, life ultimately must produce tedium and ennui; and, thanks to Providence, I used in my advanced age to feel the benefit of the magistracy of this island which my eldest daughter of Lord Latymer, who died in 1785, leaving one child, Henry. In 1787 he succeeded to the baronetcy. After the death of his wife he made an extensive tour on the continent, which occupied him nearly two years; and in 1788 he was commissioned to return until August, 1791. He devoted ample time to the drawing of interesting objects, and filled his portfolio with valuable drawings. For the gratification of his family and friends he printed the results of his travels, in two volumes, 8vo., under the title of ‘A Classical Tour through Italy and Sicily; tending to illustrate some districts which have not been described by Mr. Horace in his Classical Tour.’ When the greater part of the Continent had become closed in consequence of the war, Sir Richard travelled through his own country, and he began with Wales; but, as travelling without a parsnip becomes tedious, I believe, he says, ‘to take Giraldus as my guide.’ In 1806 he published a translation of Giraldus, with views, annotations, and a life of Giraldus, in two splendid quarto volumes. He furnished the drawings for the description of Monmouthshire by Archi- descon Cox. In 1807 he visited Ireland, and published a short account of his excursion. But he is as the historian of Wiltsihi, his native county, that Sir R. C. Hoare’s fame as a topographer and antiquary is best esteemed.

The first volume of South Wiltsihi is confined to British antiquities, and includes Stonehenge. The second volume consists of communications with North Wiltsihi, and includes a visit to the British Museum, and an account of Avebury. Part II. comprises the Roman Period. These two elaborate volumes were followed in 1821 by the History of Modern Wiltsihi, in six volumes, 8vo., of which a fourth edition was issued, in 1843. The first edition was dedicated to a nobleman who had a coachman for each, but the difficulty of obtaining aid of this kind at length compelled him to confine his attention to South Wiltsihi. A catalogue of works printed for private circulation by Sir R. C. Hoare is given in the ‘Gentleman’s Magazine’ for July, 1838, which also contains a list of his communications to the Royal Society of Antiquaries.

HODGES, WILLIAM, R.A., was born in London about the second week of January 1744; his father was a blacksmith, and kept a shop in St. James’s Market. He attended Shipley’s drawing school when very young, and became afterwards the pupil of Wiltsihi the landscape painter. He painted decorations for theatres, landscapes, and architectural views; among the latter, a view of the interior of the Pantheon, Oxford Street, which was burnt down on January 14, 1792.

In 1778 Hodges accompanied Captain Cook as draughtman on his second voyage to the South Seas; and his drawings were published in Cook’s narrative. After the completion of this work he went to India, where, under the patronage of Warren Hastings, he resided some six years, and returned to London in 1784. About 1790 he made a tour on the Continent of Europe, visiting Russia; and he exhibited a view of St. Petersburg at the Royal Academy in 1795. In 1795, finding that his Indian fortune was not increasing, he settled at Dartmouth in Devonshire, which however broke two years afterwards in consequence of the devastations of the French in Newfoundland. The short time spent on the decks of the Victory, under the command of Lord Nelson, and his wife, his third, died a few months afterwards. He was elected a member of the Royal Academy in 1787. Hodges was not a painter of great ability, in style he imitated Wilson, but with little success; his best works are—a view of Windsor from the great park, and three or four views printed in India. He painted also two or three historical pieces for Boydell’s Shakespears. His last works were two ordinary landscape paintings illustrating the effects of peace and war, which he exhibited with twenty-three others, one of which was a large view of Falconet’s equestrian statue of Peter the Great at St. Petersburg, in Old Bond Street; one was a seaport in prosperity, the other was the same view devastated by fire and sword. He closed the exhibition in disgust at the little attention which it attracted; sold his pictures by auction, gave up painting, and, as already mentioned, turned banker. These two pictures, returned to the dust, were re-graved, are now in Sir John Soane’s museum. Several of the works of Hodges have been engraved; he himself executed a set of Indian views in aquatint which he dedicated to the East India Company, and published also an account of his Travels in India, with plates.

(Edwards, Anecdotes of Painting, etc.; Literary Gazette.)

HOENE, referred to in F. C., from Hume, p. 357, is a native of Brunswick, and is said to have claimed that the bridge of Osnabriick which Prince Henry of Prussia’s battery was built on was TRAVERSING, P.C.}
HOERBERG, PEHR, a distinguished Swedish painter, was born in a village of Sniaaland, in 1746; his father was a private soldier and extremely poor. Hoerberg's youth was spent in getting along by various means, at one time as a servant's laborer; and like Giotto's, his first efforts were made with sticks and chalk in the woods when performing his pastoral duties. When only fourteen years of age he entered the service of a painter, and was told that he would never become one as a very short time in his life. However, by the time he was twenty and twenty years of age, he contrived to learn so much from one painter and another in his own district, that he was enabled to maintain himself also as a wandering artist, and he even ventured to take a wife. In 1784, in his thirty-eighth year, he became a student in the Royal Academy of Arts at Stockholm, in which he obtained two prizes, and made rapid progress. In 1790 he established himself in Copenhagen, and in 1805 he obtained a great reputation, and in 1797 he was elected a member of the Swedish academy, and was appointed historical painter to the king. He died in 1816.

There are eighty-seven altar-pieces by Hoerberg in Sweden, five of which are copies; his paintings altogether amount to about 700, mostly religious pieces; his drawings are likewise numerous, and he executed many engravings.

His execution is unfinished, but his compositions are vigorous and perspicuous; and his figures are more distinguished for character than for beauty.

His autobiography was published at Upsala in 1817; it has been translated into Swedish, Danish, and the original MS. is in the library of the Gymnasion of Linköping.

(Kunstdbatt, 1922; Nagler, Allgemeine Kunstler Lexicon.)

HOLASTE, a genius of fossil Echinodermata, from the chalk and limestone of the Tertiary period.

HOLCUS, a genus of grasses belonging to the tribe Ses-}

loreicoe. It has 2-flowered glumes, the lower perfectly awn-

less, the upper usually staminiforous, with a dorsal awn; the}

palea hanging on the fructiferous glume. There are two British species of this genus. H. lanatus has the upper glume obtuse, acuminate; the awn smooth, except for a short distance from the tip. It grows in meadows and pastures. H. mollis has the upper glume acute, and the awn rough throughout its whole extent. It grows in thickets or open places on a light soil. The H. cernus of Wildenow, and the H. sorghum of Linnaeus are now referred to the genus Sorghum. [Sorog-}

num, P. C. Fras refers the species of Theophrastus (Hist.-}

Pl. vii, 1, 8, 7, 10) to these grasses, and not to the Setaria}

Italica, as had been done before by previous authors.

HOLL, ELIAS, a distinguished German architect, was}

born at Augsburg in 1573. His father, Johann Holl, was a}

 Likewise an architect, and was much employed by the cele-

brate grand-ducal family of the Palatine principality, and was taken to young to Venice, by a rich merchant of the name of Garb; and he there studied the Italian architecture, which style he adopted for all his buildings at Augsburg, though much modified in parts, in accordance with the local arts. He added a great portion of his public buildings, but his masterpiece is the Rathhaus, or town-hall, built 1615-20, which, though not among the largest, is still one of the best executed in Europe. The facade is 147 feet wide, its depth is 110 feet, and in the centre 152 feet high; there is a print of it by Solomon Kleiner. Holl built also several churches, and the castle or palace of Schönfeld, and the palace of Willibaldsburg at Eichstätt. He died in 1636, aged sixty-three.

(Von Stetten, Erkärten und der in Körper getrockneten}

Vorlesungen aus der Geschichte der Reichsstadt Augsburg,}

etc., 1865.)

HOLLAND, SIR NATHANIEL, historical, landscape, and}

portrait painter, was the third son of Dan, the architect of}

the Mansion House, who died in 1768, and the younger brother of Nathaniel and R.A., the architect and painter.

Nathaniel Dance was the pupil of Hayman, and he studied also a few years at Rome. He was one of the original thirty-six members of the Royal Academy, founded in 1768, though he was not born at any time more than twenty-five years of age. He contributed many works to the academy exhibitions as Sir Nathaniel Holland, as well as Nathaniel Dance. He changed his name to Holland upon his acquisition of a fortune in 1800, having previously resided at Dummer, who was connected with several noble families. This lady was possessed of entail estates, chiefly in Hampshire, including Netley Abbey on the Southampton river, to the value of 19,000l. per annum. Upon his acquisition of his title, Sir Nathaniel Holland appears to have resigned his academical diploma, for from that time he exhibited as an honourable exhibitor. He represented for some time the property of the Holland House, near Winchester, and he died suddenly in that city on October 15, 1811, aged about sixty-eight. Lady Holland survived until 1825, when she died, leaving personal property to the amount of 15,000l. She came to her nephew the late Earl of Cardigan, who was her sole executor and residuary legatee. A story was circulated about Sir Nathaniel Holland, that when he became possessed of his great fortune he repurchased for him that he spent thousands in the repurchase of his own works, for the purpose of destroying them to obliteriate the recollec-

tions of his ever having been an artist. This story, how-

ever, independent of the veracity of the reports received from some of his friends, is contradicted also by the facts of his continuing to paint and exhibit, and of his presenting pictures to his friends; it is also absurd to suppose that people of rank would part with the portraits of their relations for a pecuniary consideration to the painter, to enable him to destroy them. The report was no doubt magnified from the fact that he destroyed some of his own works in his own possession, because he thought that they were not calculated to add to his reputation. All his best works however still exist, but chiefly in private collections. The Marquis Camden and Sir W. Wyne contributed three to the exhibition of the works of Sir Nathaniel Holland, at the British academy in 1817—Orpheus, and Garrick as Richard III.; two of his very best works; and Charles, Earl Camden, Lord Chancelor. The following are also among his best works:

The Portrait of the Duke of York; The Group of the General Hall; Virginia, scraped in mezzotint by J. G. Haid; and the death of Mark Antony, engraved by T. Watson. Dance painted many portraits, including both royal personages and peers, and latterly to some landscapes; for the last work which he exhibited was 'A View in the New Forest.'

It has also been reported that Sir Nathaniel saved 200,000f. out of his wife's income, and bequeathed it to his relatives, but this report is contradicted by the fact that he distributed only 30,000f. among his relations, the residue was bequeathed to his widow.

These reports have here noticed, more particularly because they have been carelessly repeated and with considerable asperity by the writer of the Article on GIANE Dance in this work. [P. C. S.] They appeared in the ' Gentleman's Magazine' for 1811, and in part, in 1825, but have been con-

tradicted in subsequent editions of Pilling; and upon their insertion in 1834 in the 'Somerset House Gazette,' they were immediately afterwards contradicted in that same work, and an apology was made for their appearance. The statements of the 'Gentleman's Magazine' were apparently not seen by any of Sir Nathaniel's family, or that work would have certain-

ly contradicted them also.

(Somerset House Gazette, 1824; Gentleman's Magazine, 111, 1811; An Account of all the Paintings that were in the Rooms of the Trustees, belonging to the House of Commons, from 1813 to 1829.)

HOLLAND, HENRY, holds a high rank among the architects of his own time, and was greatly patronised by George IV. when Prince of Wales. But we have no right to think that by Holland himself, the only instance of such classical decoration among the whole of our modern classical porticoes— but even the very bases of the columns were enriched with carving, a species of decoration never before known in England, being so near the eye, it challenged direct and minute observation. Being only hexastyle—and there was not at any time such an instance of an octastyle in the metropolis—it did not make so far reaching an impression. This is peculiar in its proportions, which so many later examples do; yet it excelled all before or since in its bold projection from the building, which rendered it of the highest proportions in that respect, although unfortunately, its rapidity of execution diminished it. The orders are carried on each flank, in order to obtain an interval sufficiently wide to admit carriages. The depth and consequently the effect of the portico was still further increased by its being also recessed within the building, by which it was rendered very-

Digitized by Google
nearly a square in plan, the depth being almost equal to the breadth. The Ionic colonnade seen in front of Carlton House was censured at the time, not for its real deficiencies, but as an architectural absurdity in itself. It was objected as a conclusive argument against it, that the column supported not one but two stories, and that the lower part of its entablature, and the entablature was requisite for connecting together the two gateways; therefore had there not been thus two stories, there would have been a wall, shutting out a view of the portico from the street.

While Carlton House and its fine portico have disappeared without being recorded by any engravings intended as actual representations of the building, the entrance at the first towards them, the entrances to the Public Buildings of London being both too few and upon too small a scale to serve much purpose, another work of Holland's, for the same royal patron, and which has also disappeared, though in a different manner—namely, the Pavilion at Brighton, as it existed previously to its being transformed into its present shape by Nash,—has, luckily for the credit both of the architect and his princely employer, been preserved in Richardson's 'New Vitruvius Britannicus.' As a residence for the Duke of York, Holland altered Featherstonehaugh House, Whitbourn (built by Paine), adding to it the elliptical entrance-hall, on what was originally the west front. This, which was afterwards called Melbourne House and is now Dover House, would have been in every respect a far worthier and more interesting subject for the Vitruvian school than the Dutch mansion is, as is apparent from the comparison. In it, the edifice made scarcely any pretensions to architecture externally. He was the architect of another building in the metropolis, of considerable architectural distinction, the India House, Leadenhall Street, the cost of which has, rather strangely, been generally given to Richard Jupp, who was only the Company's surveyor, and the conductor of the works, the design, and consequently the architecture, belonging to Holland. And the design is in some respects unusually florid in character, the science of the portico (a recessed Ionic hexastyle loggia) being highly enriched, like that of Carlton House, the pediment filled in with sculpture, and its architrave surmounted by a screen. The architrave, the rest of the façade however is by much too plain and unpretentious to accord with such degree of embellishment confined to the centre of it, and the rustication of the ground-floor augments, instead of diminishing the effect of the edifice. The difference between the façades of Carlton House and Dover House. The entablature of the portico is suppressed elsewhere, the cornice alone being continued along the rest of the front, for which there is some reason, since otherwise the cornices of the windows would have joined the architrave. England's other work was alterations in the mansion built by Brown [Browns, P. C. S.] at Claremont, and added the colonnade screen wings to the Assembly Rooms at Glasgow.

He died at his house in Hans Place, Sloane Street, Chelsea, on 9th June, 1785, at the age of seventy-three, and therefore he lived to witness the destruction of his Drury-Lane by fire and that of Carlton House, his finest work, by demolition.

HOLLAND, HENRY RICHARD VASSAL FOX, LORD, was the only son of Stephen, second Lord Holland. His mother was Mary, daughter of John Fitzpatrick, first Earl of Upper Ossory.

Sir Stephen Fox, Knight, distinguished for his magnanimity and public spirit, as well as for his great wealth, having, in 1705, at the age of seventy-six, married a second wife, Christian, daughter of the Rev. Charles Hope of Naseby in Lincolnshire, had by her, besides a daughter, two sons, Stephen, who succeeded his grandfather, dying early in his nine. Stephen became Earl of Ilchester; and Henry, who figures in our political history as the rival of the first Pitt, was, in 1765, raised to the peerage as Baron Holland, of Foulney, in the county of Wilts, his lady having the year before been made Baroness Holland, of Holland, in the county of Lincoln. Both baronies passed to their descendants. The eldest son of the first Lord Holland was Stephen, the second lord; his second son was the Right Hon. Charles James Fox, the celebrated orator and statesman.

The subject of the last reign were born at Winterlow House, in Wiltz, 21st November, 1773. On the 9th of January, 1774, that mansion, a splendid building, was destroyed by fire, in which the young lord lost his fortune, he had incurred the flames, his mother, who rescued him at the risk of her own life, having, however, in so doing, taken probably the only direction by which she could have made her escape.

On the 1st of October, 1790, he was created Lord Holland; on the 24th of the same month, his grandmother Lady Holland; and on the 26th of December in the same year, his father, the second Lord Holland; on which he succeeded to the peerage, when he was little more than a twelvemonth old.

His mother died in 1778, and then the care of the child's education devolved on her brother, the Earl of Upper Ossory. After being saved for some time at a school in the country, he was sent to Eton, where he spent eight or nine years, and where George Canning, Mr. Frere, the present Lord Carlisle, and other persons who subsequently rose to distinction, were among the companions of his youth. In October, 1790, he was entered as a gentleman at Christ's Church, Oxford; but all that is told of his academic career is that he took the honorary degree of master of arts, in right of his rank, in June, 1791.

It appears to have been before leaving the university that he made his first visit to the Continent, in the course of which he saw Carlisle, the residence of his cousin, the Earl of Derwentwater. He is stated to have been present when Louis XVI. accepted the constitution (as revised), after being brought back from Varennes, which was on the 18th of September, 1791. In March, 1795, he went abroad a second time, and, France being now closed, directed his course to Spain, over a great part of which country he travelled, studying the language and literature, and making himself acquainted with the character and manners of the people. From Spain he proceeded to Italy; and there, at Florence, in the beginning of the year 1795, first met Lady Webster, the wife of Sir Godfrey Webster, with whom he returned to England in June, 1796, and whom he married the next year, after she had been divorced from her first husband, who obtained 6000l. damages in an action against Lord Holland. (See the particulars in the Annual Register for 1797, pp. 10, 11.) After his marriage with Lady Webster, Lord Holland assumed, by sign manual, her family name of Vassal, which however has been laid aside by his children.

He now took his place in the House of Lords. His first speech was made 9th of January, 1798, on the motion for committing the bill for trebling the assessed taxes. He addressed the House both early in the debate, and again at the close, in what is described as having been a very animated and successful exertion of the Younger Grenville. He united in a high degree the young peer on the ability with which he had spoken, had noticed some of his remarks in a way that was considered to be personal. On the division, nevertheless, Lord Holland found himself one of a minority of six against seventy-three; so that he had early and emphatic experience of the position in which he was to pass the greater part of his political life. He began also on this occasion a speech in which he probably carried to a greater extent than any other peer ever did, by entering a long protest against the bill on the Journals of the House. This first of Lord Holland's long series of protests was one of the very few exceptions that occurred for the constitutional information they contain, was signed only by himself and Lord Oxford (the present peer).

From this date Lord Holland took a frequent part in the debates for the next four years, being all this time one of the chiefest opponents of the administration, and seconding in the Upper House the principal efforts of his uncle Charles James Fox in the Commons. Among other measures which met with his opposition was the Union with Ireland, which he contended (8th May, 1800) would both impoverish that country and endanger the constitution of England. A few days before this (on the 50th of April) he had moved that the House of Lords appeal to the British people, and he was considered by a Committee of the House. This motion, the first of the kind that had been made in the Lords, was got rid of by the previous question without a vote.

Meanwhile, in 1800 before the war was suspended, he
had paid a visit to Germany, and returned from Dreden by Cologne and Brussels, having obtained a French passport from Talleyrand, and liberty to make use of it from Lord Grenville, then foreign secretary. In the summer of 1802, after the conclusion of the Peace of Amiens, he repaired, with Lady Holland, to Paris, and was there soon after joined by Mr. Fox, along with whom he was introduced to the first council. From Paris, Lord and Lady Holland proceeded thenceforth to Brussels, and then to London, in that conveGENCY till after the breaking out of the war with England in January, 1805, returning home through Portugal by means of passports obtained through the Prince Regent, who had been in attendance in the House of Lords; and his name, as before, appears frequently in the reports.

He was not admitted to office during the ministry of Mr. Fox and Lord Grenville (January, 1806); but on the 28th of August he and Lord Auckland were appointed joint-commissioners and plenipotentiaries for arranging and settling the several matters. In discussion between this country and the United States, with Mr. Munro and Mr. Pinckney, the United States commissioners; and on the 27th of the same month he was sworn of the privy council. An arrangement of the differences with America was effected after a long negotiation (with the omission however of the impressment question); but Mr. Jefferson refused his ratification, and it came to nothing. On the 15th of October, after the death of Mr. Fox, Lord Holland was appointed lord chancellor, and he held that office for the six months longer that the Grenville ministry lasted.

In 1806, Lord Holland became an author by the publication of 'Some Account of the Life and Writings of Lope de Vega,' in two octavo volumes. This work, which was re-published in 1817, when it was extended to two volumes by the addition of an account of Guillin de Castro and other matter, was creditable to his lordship's native familiarity with the popular parts of the Spanish literature, without being very learned or profound. It had the merit, or luck, of leading the way in the revival of that interest in the literature of Spain which has since proved so exceedingly extended in this country, though it spread more rapidly at first than it has done of late years—a difference to be attributed partly to the allurement of novelty and the promise held out by an unexplored field, but more perhaps to the political circumstances and events which for a time drew so much attention to everything Spanish. Lord Hol
day followed up his Life of Lope de Vega the next year by another octavo volume entitled 'Three Comedies from the Spanish,' and in 1808 he edited and introduced by a preface of some length Mr. Fox's fragment entitled 'A History of the early part of the Reign of James the Second.'

On the breaking out of the Spanish insurrection in the last year of his life he had obtained leave to visit the peninsula; and he remained there till the latter part of the year 1809. The rest of his public life for many years was a continuation of the same course of opposition to the policy of the Whig ministry as that which he had pursued after his entrance into parliament. He took a leading part in most of the great questions that came before the House of Lords, and particularly distinguished himself by his support of Sir Samuel Romilly's law amendments, by his advocacy of Catholic emancipation, and his opposition to the orders in council, the cession of Norway, and the detention of Bonaparte at St. Helena. However opinions may differ as to the positive wisdom of his politics, the praise at least of consistency cannot be refused to him. He was one of the steadiest Whigs of the school of Mr. Fox. But in those days the boundaries of party were much more distinctly marked than they are now; and although the first kind of inconsistency that was the worst was going over openly from one camp to the other, changing from Whig to Tory or from Tory to Whig. These two great parties were relatively more distinct, and did not slide off into one another as they do now.

When the unsuccessful attempt was made through the Marquess Wellesley to effect a union of parties in January 1813, and in the same month he applied again to the Prince upon that principle Lord Holland should occupy the post of First Lord of the Admiralty. Like the majority of his party he supported without joining the ministry of Mr. Canning in 1822, and he made what has been called the best speech in introducing the Bill for the repeal of the Test and Corporation Acts to the House of Lords. At last, on the accession of the Whigs to power in November 1830, he became once more a cabinet minister as Chancellor of the Duchy of Lancaster; and this office he held (with the exception of the ministerial interregnum of a fortnight in May 1832, and Sir Robert Peel's four months' tenure of power from December, 1834, to April 1835) till his death at Holland House on the 28th of October 1840. He was succeeded by his son, the present Lord Holland.

The only performances which Lord Holland sent to the press between these events are already mentioned in the first of the Rev. Dr. Shuttleworth in favour of the Catholic Claims,' svo., Lon., 1837, and 'A Letter from a Neapolitan to an Englishman,' which is stated to have been privately printed in 1818; but the public character can hardly be beyond suspicion, except by Mr. Marat of a conversation which his lordship had had with him. He is also the author of a translation of Ariosto's Seventh Squire, which Mr. Stuart Rose has printed in an Appendix to the Fifth Volume of his translation of the Orlando Furioso (1837), together with a version of the 25th Canto of that poem, which is stated by Mr. Rose to be the performance of an old schoolfellow, who may perhaps be Lord Holland. As a speaker Lord Holland was more animated than graceful; when he began, in particular, he was usually for some time extremely impeded and embarrassed; and he never rose from this hesitation into any thing like the free and impetuous torrent of argument or the impassioned declamation by which his relative Mr. Fox, after a similar unpromising outset, used to carry every thing before him. But his speaking had always the great charm of honesty and earnestness, and it was certainly more common and ever little of what could be called brilliancy, a well-informed and full mind. Lord Holland was much beloved by an extensive and varied circle of friends as perhaps any man of his age and condition. His reputation, however, is chiefly earlier history, was during all his lifetime the resort of the most distinguished persons both in the world of politics and in that of literature.

(Hallam's 'History' of England, 1843.)

HOLSTEIN (from Saks, 'all,' and ster, 'a bone,' an antiphrasis applied to this plant because it is soft and unlike bone), a genus of plants belonging to the natural order of the Caryophyllaceae, and extending in the wild state to the temperate and northern regions; 5 petals, toothed at the end; 5, 4, or 5 stamens; 3 styles; a subhymenopus many-seeded capsule, opening at the end, with 6 teeth. The species of this genus are herbs with nothing to recommend them for use or cultivation. One species, H. umbellatam, is British. It has umbellate flowers, pinnate viscid peduncles, the pedicels reflexed after flowering, the leaves scuse, elliptical, or oblongate. It is not a common plant, but has been found growing wild in some few places in Norwich, Burly St. Edmonds, Eye, and Yarmouth.

(Ballington, 'Manual of British Botany.)
executed at that time in Germany; and Holzer is by some considered the founder of the new era of German fresco painting. They are however now in a most dilapidated condition; the church is in a ruinous state, and the convent is a pappel mill. Holzer was the friend of the Frankish Convent of Schwarzaeh in his accounts of the works of art in Franken, though it contains many works besides the frescoes of Holzer; those painted by Pirocco and Tello, but they are said to be inferior to those by Holzer. Holzer painted the cupola and ceiling of the church; the subjects represented are—the Glorification of St. Benedict; the Three Holy Hierarchs; St. Stephen; and St. Felicia and her Seven Sons; the Foundation of the Convent; and the Papal Confirmation of the Foundation. The martyrdom of St. Sebastian is described as the most successful composition.

After the completion of these works, Holzer was invited by the prince bishop of Wurzburg to paint his palace, for which he made the designs, but they were not satisfactorily

to the bishop. He was in the meanwhile invited by the Elector Clement of Cologne to paint the newly established capuchin convent at Clemenswerth, and he accordingly immediately prepared himself for this work. He however did not live to commence it; he died of a fever at Clemenswerth, a few days after his arrival, in July, 1740, at the age of thirty.

Holzer's works are described as successful in every department of art, in invention, form, character, light and shade, and he was considered an admirable landscape painter. Two of them have been published in Germany; the first in 1765, at Augsburg, and the last in the Tyrol in 1824. In the latest accounts he is called Johann Evangelist Holzer; see Nagler, Kunstlexicon, 2nd and 3rd.

(See, 'Leben Johann Holzers,' printed in Meusel's Musikalisches Artistisches Jahrbuch, 1871.)

HOMopathic, the art of curing founded on resemblance, and expressed in the Latin expression 'similia similibus curantur.' It is derived from the two Greek words συμφερειν, 'similar,' and εἰμι, 'being' or 'sensation,' and hence a condition of body, such as that of disease. According to this law, disease is cured by remedies which produce upon a healthy person effects similar to the symptoms of the complaint under which the patient suffers.

This system of medicine stands in direct contrast to that founded upon the principle of treating diseases by their opposites, contraria contrariis curantur, which has served more or less as a guiding law since the time of Galen. To this last method the disciples of the new school have given the name of Allopathy, from the two Greek words αλλοι, 'other,' and θεραπευειν, 'treatment.' This distinctive nomenclature will be adopted in this article as a matter of convenience, and to avoid the circumlocution sometimes employed. The contraries seem to be distinct from their opposite, and from popular experience, from observations upon the effects of medicinal agents recorded in the medical schools of various epochs, and from experiments upon healthy individuals made by the founder of the system and his disciples themselves. In his Popular experience has proved that the safest manner of restoring the circulation of a frozen limb is to rub it with snow (similia similibus); warm applications, according to the evidences of the same experience, would cause the destruction of the part affected (contraria contrariis).

Again, severe burns are most quickly cured by the use of heated spirits of wine or oil of turpentine, which excite a very similar sensation, although in a greatly modified degree (similia similibus). Cold applications, although they give temporary relief, are, as is well known, generally followed by increased inflammation and severe after-suffering (contraria contrariis), as corroborated by the evidences of John Hunter, Kennish, Sydenham, and other medical names of high repute.

The homopathists also insist that the acknowledged efficiency of Jenner's great discovery is a powerful argument of the truth of the homopathic law, since by producing a similar disease an almost perfect immunity from attacks of the small-pox is obtained.

2ndly. They endeavour to show by a number of observations compiled from the records of the homopathic schools, that many drugs recorded by them as curative in different forms of disease were observed by others, also allopathists, to produce effects closely resembling the symptoms of those very forms of diseases; or in other words, that they acted upon the principle, similia similibus: an instance or two will be sufficient illustra-

tion. The English sweating sickness, which committed such ravages in the year 1485, and for some time baffled the physicians, yielded, according to Willis, to sudoration; and it is upon record that after the adoption of this mode of treatment very few died of it. Homoeopathic surgery, the appearance of the wounds and swelling, the relief in bleeding, the fever and heavy and deep sleep; and it has, according to the testimony of many allopathic physicians, proved curative in diseases characterized by similar symptoms. Moreover, it is asserted by the homoeopathists that all the remedies of medicine are attributable to the same power (similia similibus), and as above stated, that the action of vaccine matter, as a prophylactic or preventive medicine against small-pox, depends upon the same law.

Assuming, therefore, that the position of the homoeopathists is supported by the arguments which they adduce, and that the law upon which specific action has been clearly ascertained, it would seem to be incumbent upon those who have dedicated themselves to the advancement of the healing art to endeavour, by personal experiment and careful observations upon the effects of medicines upon the human body in health, to add to the numbers of this class of remedies, and in this manner materially to improve the treatment of disease. This view of the subject appeared to be corroborated by the work of Dr. Hone, and other great names in medicine. Dr. Alison, professor of the University of Edinburgh, observes, 'The increasing efficacy and usefulness of our art must depend upon the progress which may be made in the discovery of the cures. The homoeopathist may counteract the different diseased actions of which the body is susceptible as effectually as the cinchona counteracts intermittent fever, or citric acid the sour, or the chloride of iron the stertor of sleep.'

In his 'Principles of Medicine,' Dr. Samuel Hahnemann, the founder of this system of medicine, being struck, as noticed in his life [Hahnemann, P.C.S.], with the close analogy between the symptoms produced by Peruvian bark and those of the forms of disease for which it was considered a specific, and having obtained similar results from other medicines tried upon his own person, was led to the discovery of the homoeopathic law; and he, believing that the mode of operation of all remedial agents was in perfect harmony with this principle, by repeated experiments upon himself and some medical friends, converted to his opinions, first determined their direct action and then employed them in disease. The practical results obtained by himself and the physicians of his school are appealed to by them as a further confirmation of the truth of their fundamental law.

The extremely minute quantities in which the remedies are administered seem to form a marked difference between the homoeopathist and all other schools of medicine. The homoeopathists however assert that this is merely a point of practice to be determined by the discretion of the patient, and that in the application of the homoeopathic principle to the treatment of disease, it was soon found that remedial agents given in the doses usually employed acted energetically only in those cases which were already in an extremity; the influence by the affinity existing between their medicinal effects and the morbid signs of the disease; and hence a gradual diminution was made in the quantity of the medicine exhibited, in order to approximate to that amount which might exert its full curative power without aggravating the sufferings of the patient by an excess of medicinal action.

The result has been, the universal adoption among homoeopathists of the minute doses at present in use, which perhaps more than any other cause, from its discrepancy with generally received opinions, has prevented any impartial investigation into the principles of the new system by the profession at large.

Homoeopathic numbers in its ranks many medical men who had obtained high repute and professional eminence in the other systems before they embraced the doctrines of homoeopathy, and seem to be more or less diffused in all parts of the world, so that one form any opinion from its literature, which comprises medical works in German, Italian, English, French, Swedish, Russian, Spanish, Latin, and Portuguese. The system has also adherents in North and South America and Asia. The great bulk however of the medical profession are more or less opposed to its adoption.

HOMICIDE [Murder, P.C.]

HONE, WILLIAM, was born in 1779 at Batli, where
his father is stated to have been an occasional preacher among the dissenters. He is said to have been so rigid in his religious notions that he would not suffer his son to be brought to read out of any other book than the Bible. William was placed at the age of ten in an attorney's office in London; but after some time his father, finding that he had attached himself to the law, determined to take part in what he seems to have thought very objectionable politics, removed him to another master at Chatham, with whom he remained between two and three years. He then returned to London and entered into business as a bookseller and stationer of Gray's Inn; but at last he quitted the law and, having married, set up in July 1800 as a bookseller, with a circulating library, in Lambeth Walk. For a long time after this he had struggled, but was finally successful, and in 1806 he brought out his first publication, an edition of Shaw's 'Gardener.' After this he devoted much of his time to an attempt which he made in conjunction with a friend to establish a savings bank in Blackfriars Road, which, however, failed. He then entered into partnership as a bookseller with this friend, Mr. John Bone; but the speculation ended in bankruptcy. When he got upon his feet again he established himself in a shop in May's Buildings, whence he removed to High Street, Bloomsbury; and here he appears to have remained till 1811, when on the retirement of Mr. John Walker he purchased him out; but it is called in the Trade Auctioneer, and placed in a counting-house in Ivy Lane. Before this he had been employed to compile the Index to the new edition of Lord Berners's Translation of Fables, and to the work of an ancient, and, he thought, to have taken to the investigation of the abuses in lunatic asylums, he soon became bankrupt again. The date is not given in the account from which our abstract is derived; but it is stated that he had seven children, whom he took to a humble lodging in the Old Bailey, and endeavoured for a time to support by contributing to periodical publications, especially the 'Critical Review' and the 'British Lady's Magazine.' At length, however, he found means to set up once more as a bookseller in a small shop in Fleet Street. Here he was again unfortunate in having his premises twice broken into and plundered, much of the stock that was carried off having been borrowed; but it seems to have weathered these disasters; and in 1815, it is stated, he became publisher of the 'Traveller' newspaper. In that year he exerted himself with most praiseworthy humanity and spirit in the investigation of the case of the unhappy Elizabeth Penning, executed on a charge of poisoning of which there can scarcely be a doubt that she was innocent; and he published a very striking account of the case, modestly, however, withholding his own name as the author of it. He was then called in to give the literary credit to a Dr. John Watkins, who only contributed three letters, forming the least interesting part of the publication. The volume, an octavo of 240 pages, produced two thousand copies, and were sold at five shillings. In 1816 he commenced a weekly paper called 'The Reformers' Register,' but it does not seem to have gone on long. The next year, however, he brought himself into great notoriety by a series of political satires, published as separate pamphlets, which had immense success, the effect partly of their literary merit, partly also of the wood-cut embellishments from the clever and handsome designs of Mr. George Cruikshank, whom they first made generally known to the public. One of them, 'The Political House that Jack Built,' went through fifty editions, besides producing a host of imitations. Their father, excited by the storming attack upon the since defunct daily morning paper called 'The New Times,' its editor Dr. (afterwards Sir John) Stoddart, and the Constitutional Association, or 'Bridge Street Gang,' stated (in the Independent) that his book turned out the most productive for the authors were three composed in the manner of parody upon various parts of the Book of Common Prayer. For the printing and publishing of this he was brought before the Justices for some restitution of smaller indictment in the Court of King's Bench, on the 18th, 19th, and 20th of December, 1817; the first day before Mr. Justice Abbot and Mr. Justice Tenterden, the second and third days before Lord Eldon. He was found guilty on all three trials (which were before special juries); and, notwithstanding the best exertions of the bench to procure a conviction, was acquitted on each indictment. His address to the jury on the third day, especially, which lasted seven hours and a half, although the latter part was not to be taken for what he seems to have thought very objectionable politics, removed him to another master at Chatham, with whom he remained between two and three years. He then returned to London and entered into business as a bookseller and stationer of Gray's Inn; but at last he quitted the law and, having married, set up in July 1800 as a bookseller, with a circulating library, in Lambeth Walk. For a long time after this he had struggled, but was finally successful, and in 1806 he brought out his first publication, an edition of Shaw's 'Gardener.' After this he devoted much of his time to an attempt which he made in conjunction with a friend to establish a savings bank in Blackfriars Road, which, however, failed. He then entered into partnership as a bookseller with this friend, Mr. John Bone; but the speculation ended in bankruptcy. When he got upon his feet again he established himself in a shop in May's Buildings, whence he removed to High Street, Bloomsbury; and here he appears to have remained till 1811, when on the retirement of Mr. John Walker he purchased him out; but it is called in the Trade Auctioneer, and placed in a counting-house in Ivy Lane. Before this he had been employed to compile the Index to the new edition of Lord Berners's Translation of Fables, and to the work of an ancient, and, he thought, to have taken to the investigation of the abuses in lunatic asylums, he soon became bankrupt again. The date is not given in the account from which our abstract is derived; but it is stated that he had seven children, whom he took to a humble lodging in the Old Bailey, and endeavoured for a time to support by contributing to periodical publications, especially the 'Critical Review' and the 'British Lady's Magazine.' At length, however, he found means to set up once more as a bookseller in a small shop in Fleet Street. Here he was again unfortunate in having his premises twice broken into and plundered, much of the stock that was carried off having been borrowed; but it seems to have weathered these disasters; and in 1815, it is stated, he became publisher of the 'Traveller' newspaper. In that year he exerted himself with most praiseworthy humanity and spirit in the investigation of the case of the unhappy Elizabeth Penning, executed on a charge of poisoning of which there can scarcely be a doubt that she was innocent; and he published a very striking account of the case, modestly, however, withholding his own name as the author of it. He was then called in to give the literary credit to a Dr. John Watkins, who only contributed three letters, forming the least interesting part of the publication. The volume, an octavo of 240 pages, produced two thousand copies, and were sold at five shillings. In 1816 he commenced a weekly paper called 'The Reformers' Register,' but it does not seem to have gone on long. The next year, however, he brought himself into great notoriety by a series of political satires, published as separate pamphlets, which had immense success, the effect partly of their literary merit, partly also of the wood-cut embellishments from the clever and handsome designs of Mr. George Cruikshank, whom they first made generally known to the public. One of them, 'The Political House that Jack Built,' went through fifty editions, besides producing a host of imitations. Their father, excited by the storming attack upon the since defunct daily morning paper called 'The New Times,' its editor Dr. (afterwards Sir John) Stoddart, and the Constitutional Association, or 'Bridge Street Gang,' stated (in the Independent) that his book turned out the most productive for the authors were three composed in the manner of parody upon various parts of the Book of Common Prayer. For the printing and publishing of this he was brought before the Justices for some restitution of smaller indictment in the Court of King's Bench, on the 18th, 19th, and 20th of December, 1817; the first day before Mr. Justice Abbot and Mr. Justice Tenterden, the second and third days before Lord Eldon. He was found guilty on all three trials (which were before special juries); and, notwithstanding the best exertions of the bench to procure a conviction, was acquitted on each indictment. His address to the jury on the third day, especially, which lasted seven hours and a half, although the latter part was not to be taken for
island from cast to west is stated to be about eight miles; but its breadth is very irregular, and varies from about six miles to two miles. The coast-line forms a succession of small bays and points, most of the promontories and headlands of Hong Kong Roads and Victoria Harbour, both opposite the town of Victoria. There is deep water for a mar-of-war within a cable's length of the shore. The harbour lies between the mountains of Victoria on the north and the South Dwarkanath forest associated with that of Hong Kong. The northern side of the island is traversed by a ridge of mountains which vary in height from 600 to upwards of 1000 feet. They present a steep declivity towards the coast, and their base approaches nearly to the edge of the sea. In the map of Hong Kong which accompanies Bernard's ' Voyages of the Musussa' (London, 1844), Mount Victoria is to be found at 2872 feet high, the Mount Crouch, 1756 feet. These two mountains immediately overlook the town and harbour of Victoria. The elevation of Mount Parker, at the other or eastern end of the island, is said to be 1711 feet. The mountains furnish a supply of excellent granite for building; and there are numerous quarries which are skillfully worked by Chinese labourers. The southern side of the island is much less rugged, and consists of an undulating surface with occasional portions of flat land. The total quantity of land suitable for cultivation is small, and the greater part of it is in one valley. Deep ravines extend from the interior towards the coast, and extend far back. The author says, 'The words Hong Kong are in fact a corruption of Hoong Keang, or the red torrent,' so called from the colour of the soil through which flows a stream that tumbles over a cascade adjacent to the site of the present town. On the 27th June, 1843, was 88°. On one occasion the thermometer rose to 92° during the middle of the day, and once only fell to 84° during the night. (Bernard.) In October, November, and December the variations of the temperature are often from 10° to 20° in the course of twenty-four hours, and the feeling of cold is greater than in many northern countries in the same months. The northern side of the island is fully exposed to the south-west monsoon, and has the serious disadvantage of being deprived by the mountains of the south-western monsoon in the hot season. At that season the climate is excessively hot, and this is succeeded by a hot unclouded sun, which acts upon the undrained parts of the surface and creates malaria. The healthfulness of the island may doubtless be improved by attention to drainage and the formation of channels for carrying off the superabundant moisture. In the cold season, when sudden variations of temperature occur, the practice of the natives should be followed, who prudently increase the warmth of their clothing at the proper time. The south side of the island enjoys the benefits of the south-western monsoon, and is healthier than the northern side; but it is destitute of a harbour of sufficient extent. The merchants of Victoria might, it is thought, have obtained this side, and at the same time proceed daily to their business.

Hong Kong was taken possession of by the British during the war with China. The cession of the island formed one of the principal conditions of the Treaty of Nanking, signed Aug. 30, 1842, they gave up the island of Chuen, and Hong Kong was ceded in perpetuity to Great Britain. The wisdom of this selection has since been doubted. [CHIABAR, P. C. S.] On the 26th of June, 1843, Hong Kong was regularly constituted a British colony. It is what is called a crown colony, that is, it is not under the control of separate assembly, but it is governed by orders from the Colonial Office at home. There is a legislative and executive council to aid the governor with their assistance and advice. The governor, as superintendent of trade, is head of the consular representatives at the five ports opened in pursuance of the Treaty of Nanking. The offices of the government are at Victoria. There is a chief justice and attorney-general, with other law-officers, and the usual departments of a colonial administration. All grave offences committed by British subjects must be tried at Hong Kong. There are four newspapers published at Victoria. At the present time the number of Chinese inhabitants was supposed to amount to about five thousand, exclusive of the best-people and migratory labourers from the mainland. The resident population consisted chiefly of civil servants, military officers, and traders, with a few and scattered sprung villages. Since the island became a British colony there has been a great increase of Chinese, and their numbers are now estimated at upwards of 30,000. They make themselves generally useful as domestic servants, labourers, tailors, shoemakers, builders, carpenters, &c., and they become of great service in the cotton trade. In the small body of Chinese police. The command of cheap labour to any extent has been one great cause of the rapid progress of the town of Victoria. In June, 1841, when the British were in possession, there were only about 150 Europeans, and 13 Chinese. From Canton, there was not a house on the island fit for the residence of Europeans, and Sir H. Pottinger, the plenipotentiary, lived, when on shore, in a tent. During the two months that the fleet remained here, a few neat sheds and temporary huts were erected; but in the month of August, 1841, the site of Victoria was still covered with brushwood. Within a year after the first house was completed, there had been constructed regular streets and buildings, Chinese, numerous large storehouses, substantial wharfs and jetties, two European hotels and billiard-rooms, and various public buildings. The government had begun the formation of an excellent road along the front of the harbour at the foot of the hills, which was carried to a distance of four miles; and it has since been extended, and other roads have also been made, and bridges erected. In consequence of the limited space between the beach and the base of the mountains, the town necessarily stretches in a line, which is about three miles in front of the harbour. The distance from one end of the town to the other is about two miles. The location of Victoria is in some other situation is thought desirable. In July, 1844, a liberal arrangement was made with a body of Chinese shopkeepers who had been allowed to settle in a district which had been declared free from the bazaar of the entrance of the harbour, and near to the centre of the European town, and they were removed to another part of Victoria, where a large number of their countrymen were already settled. The government does not grant land in perpetuity, but assigns it on lease for seventy-five years; and there is a clause under which it is to be given up at a valuation assessed by twelve jurors, on oath, if required for public purposes. In 1844 the government derived an income of 9600 dollars from the custom-house, and its revenue from this source was rapidly augmenting.

Early in 1845 the government of Hong Kong legalized the opium trade. In March of that year this illegal drug was farmed by a mercantile house at 720 Spanish dollars a month. All the houses in which opium is sold must adjoin the street, and they may be open from day-light till ten in the evening, except on Sundays, when they are to be closed. No person is to be admitted into these houses with any kind of weapon or edged tool. There is a tax on salt, and a duty of 25 per cent. on sales by auction. Victoria is a free port, and, like Singapore, its prosperity must depend upon its commerce being freed from all restrictions which can properly be dispensed with. In May, 1845, the currency was regulated by a proclamation which had previously been sanctioned at home by the privy council. The gold and silver coin is to be equivalent to 20s. 6d.; the East India Company's rupee, coined since September, 1845, to 1s. 10d.; Spanish and Mexican dollars 4s. 2d.; and 228 cash is declared to be equivalent to 20s. 6d.; the currency of the East India Company's rupee, coined since September, 1845, to: 1s. 10d.; Spanish and Mexican dollars 4s. 2d.; and 228 cash is declared to be equivalent to 20s. 6d. [BERNARD, Voyages and Services of the Nemesis, London, 1844; McPherson, Two Years in China, 1842; Loch, Campaigns in China, 1845.]

HONTHORST, or HUNDHORST, GERHARD, called by the Italian Ghirardello dalle Notti, from his night and candle pieces, was born at Utrecht in 1592. He was the pupil of A. Bloemaert, studied some time in Rome, and was engaged for six months by Charles I. in England. He painted Charles's sister, the Queen of Bohemia; the portrait is now at Hampton Court. There are also at Hampton Court—James I., when young; the Duke of Buckingham, and family; and a large painting on the queen's staircase, of Charles I. and his queen, as Apollo and Diana, sitting in the clouds, and the Duke of Buckingham below as Mercury, introducing the Arts and Sciences to them, while a celestial genie is driving away Eury and Malice. For these paintings Honthorst received 3000 florins, a service of plate complete for twelve persons, and a beautiful house. Honthorst was the first Dutchman who was appointed by Queen Elizabeth to paint the court painter to the Prince of Orange. He died at the Hague in 1650. He had a remarkable number of scholars, especially among the highest classes. Savvart also was one of his pupils. The style of execution is much like that of Guercino; his pictures occur frequently in European galleries.
HOOD, THOMAS, was born in 1798, in the Poultry, London, where his father was a bookseller, of the firm of Yeates and Hood. Thomas was sent to a school in Tokenhouse Yard, in the city, as a day-boarder. The two maiden sisters who kept the school, and with whom Hood took his dinner, had the odd name of Hogdtsen, and they had a small brother, whose name was always addressed to Charles Lamb. A Mr. H., who subsequently became the prototype of Charles Lamb's unsuccessful farce called 'Mr. H.' Hood was afterwards sent to a preparatory school, and in due course was transferred to the school in the neighbourhood of London, but derived little benefit from either.

In 1811 Hood's father died, and soon afterwards his elder brother died also. Thomas Hood being then the only remaining son of the widow, she was anxious to have him near her, and recalled him home. In 1812 she sent him to a day-school.

His account of this school and its master is so characteristic as to be worth extracting from his 'Literary Reminiscences' ('Hood's Own,' p. 292):—"In a house, formerly a suburban seat of the unfortunate Earl of Essex, over a grocer's shop, up two pair of stairs, there was a very select day-school, kept by a decayed Donnian, as he would have been called in his native land. In his better days, when my brother was his pupil, he had been master of one of those wholesale concerns in which so many ignorant men have made fortunes, by favour of high terms, love-sick, guileful parents, and victims of his knowledge. As a scholar, on the contrary, he failed to realize even a competence, it may be inferred, logically, that he had done better by his pupils than by himself; and my own experience went to prove that he attended to the interests of his school, not to the advantage of his own. Indeed he less resembled, even in externals, the modern worldly trading schoolmaster than the good honest earnest olden pedagogue—a pedant pernicious, but a learned one, with whose teaching a present authority of love, who had a proper sense of the dignity and importance of his calling, and was content to find a main portion of his reward in the honourable proficiency of his pupils. If small as was our gain, so small as easily was our power, yet infinite was our state and walked gowned and covered. His cap was of faded velvet, of black or blue or purple or red green, or, as it seemed, of all together, with a suane of brown; his robe of crimson damask, lined with the national tartan. A quaint carved high-backed elbowed article, looking like an émigré from a set that had been at home in an aristocratical dressing-room under the ancien régime, was his professorial chair, which, with his desk, was appropriately elevated on a dais some inches above the common floor. From this moral and material eminence he cast a vigilant kindly eye over some dozen of youngsters; for adversity, sharpened by habits of poverty, had fixed around him, or made it possible with the peculiar red-streak common so to the healthier natives of the north. 'In a few months my education progressed infinitely farther than it had done in as many years under the superintendence of his brothers and assistants.' I picked up some Latin, was a tolerable grammarian, and so good a French scholar that I earned a few guineas—my first literary fee—by revising a new edition of "Paul et Virginie" for the press. Moreover, as an accountant, I could work a summum bonum, that is, a good sum.'

From this school he was removed to the counting-house of Messrs. Bell and Co., Russia merchants, Warfand Court, City, but his health soon began to fail, and he was sent in a Scotch smock to Dundee, and consigned to a female relation, who however refused to take charge of him, and even reshipped his luggage, and wo did have him back to London, if Hood had not quitted his native country, and never to return, he might have become a warrior, as well as a rambler, fishing, and boating. His health gradually improved, and, after remaining two years at Dundee, he returned to London. He engaged himself to Mr. Robert Spence, who was his brother's former partner to keep his book of accounts, art, and was afterwards with Le Koux for the same purpose.

In 1821, Mr. John Scott, then editor of the 'London Magazine,' the Magazine passed to other proprietors, who happened to be Hood's friends, and he was offered the situation of sub-editor. He had published some verses in the Dundee Advertiser and Dundee Magazine, while he remained at that place, which were favourably received, but he had not been stimulated to any further appearance in print. 'My vanity,' says he, 'did not really plunge me into authorship, but no sooner was there a legitimate opening than I jumped at it, & la Grimialdi, head foremost, and was speedily behind the rest of the company.'

Hood, while in this situation, became acquainted with several persons who have distinguished themselves in English literature, and who were then contributors to the London Magazine—Mr. William Hazlitt, Carew, Prosper Ollier, Sartor, Bartlett, Hasting, Elton, Hartley Coleridge, Talkford, Soame, Horace Smith, Reynolds, Fowell, Clare, Benyon, and others.

With Lord Byron Hood afterwards fell on terms of great intimacy, which continued till Lambs death.

Hood's first publication in a separate form was 'Odes and Addressas to Great People,' in which he was assisted by his brother, and with whom Hood, Reynolds, and which was brought out anonymously. 'Whims and Oddities,' published in 1826, in small 8vo, consisted chiefly of his contributions to the 'London Magazine,' with some additions. His next work was in prose, 'National Tales,' 8vo, which was followed by 'The Plea of the Midsummer Fairies, Hero and Leander, Lyceus the Centaur, and other Poems,' 8vo, 1827, a volume of serious poetry which obtained praise from the critics, but little favour from the public. His experience of the unpleasant truth that 'Those who live to please must please to live,' induced him to have recourse again to his lively vein. He published a series of short stories, called "The Reminiscences of the World," the third series in 1828. He commenced the 'Comic Annual' in 1829, and it was continued nine years. In the same year his comic poem 'The Epping Hunt' came out, and excited much mocking from the London sporting world. He was for one year editor of 'The Gem,' and wrote for it his poem called 'Eugene Aram's Dream.'

In the spring of 1831 Hood became the occupier of a house called 'the House, belonging to the proprietor of the Wanstad, in Essex, near which it was situated. While residing here he wrote his novel of 'Tyneley Hall.' Fecundity difficulties compelled him to leave his pleasant residence. The dedication of 'Tyneley Hall' is dated Lake House, Oct. 20, 1834. He left it in 1835.

The 'Comic Annual' having terminated in 1837, Hood commenced the publication of 'Hood's Own,' in a series of monthly numbers, in 1838. It consisted chiefly of selections from the proze and poetry which he had published in the series of the 'Comic Annual,' with several additions.

A portrait of himself, for whom he sat at the request of the publisher, is attached to the work, and is, as he says himself, a faithful likeness.

Hood went to the continent for the benefit of his health, but while in Holland the unwholesome air of the marshes proved fatal to his constitution. He was placed in a single chamber, and exposed to a single fingered cold, and this with the peculiar red-streak common to the healthier natives of the north. 'In a few months my education progressed infinitely farther than it had done in as many years under the superintendence of his brothers and assistants.' I picked up some Latin, was a tolerable grammarian, and so good a French scholar that I earned a few guineas—my first literary fee—by revising a new edition of "Paul et Virginie" for the press. Moreover, as an accountant, I could work a summum bonum, that is, a good sum.'

From this school he was removed to the counting-house of Messrs. Bell and Co., Russia merchants, Warfand Court, City, but his health soon began to fail, and he was sent in a Scotch smock to Dundee, and consigned to a female relation, who however refused to take charge of him, and even reshipped his luggage, and wo did have him back to London, if Hood had not quitted his native country, and never to return, he might have become a warrior, as well as a rambler, fishing, and boating. His health gradually improved, and, after remaining two years at Dundee, he returned to London. He engaged himself to Mr. Robert Spence, who was his brother's former partner to keep his book of accounts, art, and was afterwards with Le Koux for the same purpose.

In 1821, Mr. John Scott, then editor of the 'London Magazine,' the Magazine passed to other proprietors, who happened to be Hood's friends, and he was offered the situation of sub-editor. He had published some verses in the Dundee Advertiser and Dundee Magazine, while he remained at that place, which were favourably received, but
Garrideb,' and his novel of 'Our Family,' which was interrupted by his last illness and death: the last chapters were in fact written by him when he was propped up by pillows in bed. He had the consummation, a short time before his death, of one of his most admired descriptions, or even say conceptions, which he was offered to Sir Robert Peel, transferred at his own request to his wife. After a lassitude, which continued four days, he died, May 3, 1846. He was buried on the 10th of May in Kensall Green Cemetery, in all his forms.

Hood left two children, a girl and a boy, of whom the girl is the eldest, and is now (1845) about fourteen years of age. Soon after his death a subscription was commenced in order to raise a fund for the benefit of the widow and children. This amount already realized (Nov. 1845) is between 1400L. and 1500L.

Hood was undoubtedly a man of genius. His mind was stored with a vast collection of materials drawn from a great variety of sources, but especially his own observations; and he possessed the power of working up those materials into combinations of wit and humour and poetry of the most original and varied kinds. His vigilance of observation must have been extraordinary. The appearances of nature, the forms and usages of society, the great diversity of characters, arts, professions, and trades lay ready in his mind to supply the demands of his rapid and subtle and versatible imagination. He has wit of the highest quality, as original and as abundant as Butler's or Cowley's, drawn from as extensive an observation of nature and life, if not more so, than either of these. His skill in imitations, and the richness of humour of which Butler had little and Cowley none. His humour is frequently as extravagantly broad as that of Nabbes, but he has sometimes the delicate touches of Addison. As a poet, he was merely an imitator of Addison, and the best of the imitations of Addison with double meanings of sense in such a manner as to produce the most extraordinary effects of surprise and admiration. His power of exciting laughter is wonderful, his drollery indescribable, his fine word combination, and wit of equal excellence, so that it is very great. In some of his 'National Tales,' as well as in his singular poem of 'Eugene Aram's Dream,' he produces effect upon the feelings which is sometimes little less than sublime. His 'Song of the Shirt,' which he wrote a short time before his death, was a burst of poetry and indignant passion by which he produced tears almost as irrepressibly as in other cases he produces laughter.

In his 'Plays of the Midsummer Fairies, Hero and Leander, Lyca the Centaur, and other Poems,' he supports a poetic character quite different from those in which he usually appeared. Without a trace of solemnity or affectation, he shows his imagination, his wit, and his humour, to be of the most brilliant and varied kind, and he displays a playfulness and delicacy of fancy, a tenderness and sweetness of feeling, a choice of diction, and beauty of versification, which render these serious poems exceedingly delightful; and the most delicate and the most serious plays are written from the same elaborate structure, it may be inferred that it cost him much labour, if not much time. In extenuation of the neglect of the public, it may however be observed that such poems can never be popular, and that the only way to make them is by not publishing them. The plays most admired are those of which the characters than they would have been without it. Those objections however are much less applicable to 'Our Family' than they are to 'Tylin Hall.' They are defective as novels, as well as as plays, and are often removed in acting.

The rule but graphic and humorous sketches by which many of his comic works are illustrated, are for the most part very slightly connected with the pieces to which they are annexed, and are not, in general, independent of them. But still, the wit and allusion, the perception of the make and odd fancy occurred to him.

The novel tendency of Hood's works is excellent. In the indulgence of his spirit of fun he is anything but strait-laced as regards the introduction of images and phrases which a fastidious person might call vulgar or coarse: but an indescribable joviality, to say nothing of a vein of liberal-minded, a warm eulogist as well as a glowing depicter of the good feelings of our nature and the generous actions which those feelings prompt, and he is an unassuming satirist of vice, pretension, and cant, in all its forms.

Hood, in his person, was thin, pale, and delicate. In his temper he was kind and cheerful; he scarce to his social and benevolent feeling of his friend Lamb, and he was by no less than Lamb a favourite and his friend. His long continued sufferings only stimulated him to amuse himself and others by the exercise of his extraordinary imagination, and when at last he could no longer bear up under his bodily pains, his complaint was simple, but it indicated a terrible degree of suffering—'I cannot die, I cannot die.'

(Literary Reminiscences in Hood's Own; Allusions; Genius of Mountain and Other Periodical Works.

HOOK, THÉODORE EDWARD, was born Sept. 22nd, 1778, in Charlotte-street, Bedford-square, London. He was the son of James Hook, a musical composer of some celebrity in his day, by his first wife (Miss Maddin), a beautiful, accomplished, and excellent woman. There was only one other child by that marriage, Dr. James Hook, dean of Worcester, who was born in 1773, and died February 5th, 1828. Dr. Hook married a daughter of Sir Richard Hood, Esq., of Sideway, in 1797; and wrote two musical pieces, 'Jack of Newbury,' 1785, and 'Diamant et Diamond,' 1797, which were never printed, and two clever novels, 'Pen Owen,' and 'The Scarlet Vulture.' Dr. Hook's second wife was the daughter of Hook's mother's sister; he died in 1802, while he was yet a schoolboy at Harrow; his father did not send him again to school after the funeral; and not long afterwards he married again.

Theodore Hook was a handsome and remarkably clever. He ad a fine ear, was an expert performer on the pianoforte, had a sweet and powerful voice, and sang a pathetic song well, and a comic song delightfully. His father was employed by the Earl of Oxford, and the two Hook brothers wrote songs for him, and sometimes composed the airs. The striping soon received a free admission before the curtain and behind it, and he was highly approved of his father's profits. His father, who had taken degrees at St. Mary Hall, Oxford, and has been the history of the church, seeing the danger which the young man's character was exposed to by the pressure of dissipation, persuaded his father to send him to the University, and the future dean went with him to be entered at Oxford. But in order to go through a prescribed course of reading, he was not to commence his residence at the University till February 5th, 1798, when he was 12. He returned with his father to London. He immediately set about writing an operatic farce, 'The Soldier's Return,' 1805, which was very successful, and he gave up all thoughts of the University, and devoted all his time and energy to many other successful operatic pieces and farces — but not by his own judgment, but with the consent of his father's friends, to his brother, who had taken degrees at St. Mary Hall, Oxford, and was then advancing in the church, seeing the danger which the young man's character was exposed to by the pressure of dissipation, persuaded his father to send him to the University, and the future dean went with him to be entered at Oxford. But in order to go through a prescribed course of reading, he was not to commence his residence at the University till February 5th, 1798, when he was 12. He immediately set about writing an operatic farce, 'The Soldier's Return,' 1805, which was very successful, and he gave up all thoughts of the University, and devoted all his time and energy to several other successful operatic pieces and farces — Catch me who can, 1806; 'The Invisible Girl,' 1806; 'Tecili,' 1806; 'The Fortress,' 1807; 'Music Mad,' 1808; 'Siege of St. Quintin,' 1809; 'Musikens Mand,' 1807; 'Words and Sound,' 1809; 'Awe-ass-ilation,' 1810; 'The Will, or the Widow,' 1810; 'Trial by Jury,' 1811; 'Darkness Visible,' 1811. In 1809 (he was then only twenty) he made his first essay as a novelist by the publication of 'The Man of Sorrow,' under the assumed name of Alfred Allandale, Esq. It was a very funny work, and had no success. His life at this time was a series of roguish buffooneries. In 1809 he played off only two gambols, which are recorded on record, which is known as the 'Bermers-street Hoox.' Not only Bermers-street, but all the streets connected with it were rendered almost impassable by vehicles of all descriptions laden with goods of every kind, from the heaviest to the lightest; and persons of all ranks and professions, including the Commander-in-Chief, the Archbishop of Canterbury, and the Lord Mayor; received invitations, and most of them were morally instructed, including his conversational powers, but his talent as an improvisor is described as marvellous. He was the companion of Charles Matthews; and Mrs. Matthews, his friend, was the mother of two of the most eminent instances, not only of Hook's displays of improvisation, but of the feats of mimicry which they played off separately and conjointly. Hook was invited to perform before the Prince Regent, who was much delighted, that afternoon, to the familiar exhibitions at Lady Hartford's, and elsewhere, the ingenious
declared that 'something must be done for Hook;' and late in 1812 something was done for him:—he was appointed Accountant-General and Treasurer to the Colony of the Mauritius, with a salary and allowances amounting to nearly 200l. a year. He reached his destination on the 9th of October, 1813, being then only twenty-five years of age. The climate, the society, the amusements, everything delighted him, and he indulged in the most lavish expenditure. Towards the close of 1817, General Sir John, the governor, sailed for England, and Major-General Hall was sworn in as deputy-governor during his absence. An examination of the accounts and state of the treasury took place, and the report of the audit-board, which stated that everything was right and exact. Some months afterwards, however, a man of the name of Allan, who was in the treasury department, made a declaration that he knew and had long known that there was a deficiency of 37,000 dollars. Further examinations took place, more deficiencies were discovered, and the result was that Hook was arrested on the 9th of March, 1818; all his property was seized, and he was back to England in custodi. The ship reached Portsmouth in January, 1819, and the documents were submitted to the law-officers of the crown. The attorney-general's report was, that though Hook might be liable to a civil prosecution for debt, there was no apparent ground for a criminal prosecution and had set at liberty with only two hundred pounds mohurs in his pocket. He took a small cottage in Somers Town, and formed connections with newspapers and magazines, by which he was enabled to supply himself with the proceedings of the House of Lords, and he lived in security, and was known only to a few of his old associates, such as Matthews, Terry, and Tom Hill.

In the meantime Scott was in London, and, dining one day with his old friend Terry, met there Matthews, and, for the first time, Hook. The inquiry into Hook's defalcation was still before the audit-board, and the proceedings were represented to Scott as a cruel persecution; he was much pleased with Hook's conversational powers; they were both staunch Tories; and Scott having soon afterwards been applied to by a nobleman of influence to recommend an editor for a provincial newspaper he was named Hook, however, was not destined for provincial celebrity. The 'John Bull' newspaper was established, with Hook for its editor. The career of the 'John Bull' is well known; its attacks upon Queen Caroline and her supporters, its virulence, its personalities, and the talent which raised its circulation to so great a height, Hook, in its prosperous state, received full 2000l. a year from it; and though its circulation gradually diminished, he derived a considerable profit from it up to the time of his death. Meantime the Whigs took care that the inquiry before the audit-board should not be dropped; and the result was, that at first the balance found against him was 30,000l., which on the strength of new evidence was reduced and the extent was issued for 12,000l. Hook admitted at an early date that the deficiency was 9000l., but afterwards asserted that a strict scrutiny would have struck off 3000l. from this. But there is no proof of a part of Hook; but there is proof that he himself and his officers kept the treasury books with the most culpable and scandalous carelessness, and that the keys of the treasure-chest were frequently left with underlings while he was absent on pleasure excursions. In August, 1823, he was arrested under a writ of Exchequer, his property was sold, and realized about forty pounds, and he was taken to a spunging-house in Shire-lane, Fleet-street, where he remained till April, 1824, whence he was transferred to the Rules of the King's Bench, and he remained there till May, 1825, when he was released from custody, but with an intimation that the crown would frequently be making of its claim for the debt. He then took a cottage at Putney.

Hook published his first series of 'Sayings and Doings' in Feb. 1824, while confined in the spunging-house, and his profits from this branch of his business have to be considered sums almost as large as the profits of the other works which he published in rapid succession afterwards. The following is a list of the whole of them — 'Sayings and Doings,' 3 vols., 1824; 'Remarks,' 3 vols., 1825; 'Third Series,' 3 vols., 1828; 'Maxwell,' 3 vols., 1830; 'Life of Sir David Baird,' 2 vols., 1830; 'Parson's Dog,' 3 vols., 1833; 'Love and Pride,' 3 vols., 1833; 'Gilbert Gurney,' 3 vols., 1837; 'Births, Deaths, and Marriages,' 3 vols., 1839; 'Gurney Murred,' 3 vols., 1839; 'Precepts and Practice,' 3 vols., 1840; 'Fathers and Sons,' 3 vols., 1840; 'Peregrine Bunce,' 3 vols., 1841, some months after his death. In 1830 he became editor of the 'New Monthly Magazine,' and 'Gilbert Gurney,' 'Gurney Married,' 'Precepts and Practice,' and 'Fathers and Sons,' were originally published in the series. 'The Gentleman's Reminiscences,' from Kelly's notes, in 1836, without remuneration, and merely out of kindness to his old friend.

While residing at Putney he gradually mixed more and more frequent visits to the noble house of 1617, took a box in the Clift Row, St. James's, which has since been the residence of a wealthy nobleman; he became a member of divers first-rate clubs, received invitations from persons of the highest station, and was evidently anxious to get himself and deeply into debt, notwithstanding the large sums which he obtained by his literary labours. By his ambitious and criminal extravagance, which, as supplied at a ruinous expense of labour of mind and body, his constitution, excellent as it was originally, was completely broken up. In July, 1841, when dining at Brompton, he was observed to be unwell, and as he stood with the coffee in his hand, turned suddenly to the mirror, and said, 'Ay, I see I look as I am; done up in purse, in mind, and in body too at last.'

From that time he was confined to his house. About the middle of August he requested the Rev. Mr. Gleig, chaplain of Chelsea Hospital, who was an old acquaintance, but had never been at his house, to pay him a visit. He did so, and being known to the servant as a clergyman, was admitted without a question. Hook was somewhat confused and said he was in debt; but after a moment's pause, he observed: 'Well, you see me as I am at last— all the bucklings, and pinnings, and washings, and brushings, dropt for ever— a dirty, baggage, head above water.' He had latterly been much improved. He died Aug. 24, 1841, in the fifty-third year of his age. His novel of 'Gilbert Gurney' contains a sort of autobiography of himself.

While living at Somers Town he had become acquainted with a young woman, and by her he had six children: she was respectable, and he always behaved well to her, but he had not the more romantic side of her, then, according to his diary, he had sometimes thoughts of doing so. A few hundred pounds were subscribed for her and the children after Hook's death. He was a good-natured man, and willing to do acts of kindness, but he had no moral principle sufficiently strong to restrain the impulsion of the moment.

Hook's conversational power was greater than his power as a writer. He was an admirable narrator, abounding in smart sayings, which, if not of the highest art and humour, were so said as to appear the best things ever uttered, and could intermix serious remarks full of good sense and derived from a wide observation of life. His novels are sketches rather than novels; they contain indeed excellent descriptions of the various forms of life with which he had been conversant, rapid but striking sketches of character, and laughable extravagances, conveyed in a clear, natural, and pointed manner, so true a representation of the time for a popular writer, but is not likely to continue popular long. His novels will shortly share the fate of his dramatic pieces, and be forgotten. His satirical poems are little better than doggerel, and the points, now that the circumstances which gave rise to them have passed away, seem very blunt indeed: his power in these poems was generally in the coarseness of his invectives, not in satirical wit, of which indeed he had little, and that of inferior quality. There are many songs written by him which have never been published, and it is doubtful if they are worth publication.

(Quarterly Review, May, 1842, an entertaining and instructive work, written in a fair spirit, by an editor who knew Hook well; Gent.'s Mag., Oct. 1841, a bad article, written in a spirit of absurd enmecum.)

HOOLE. (Tasso, F. C.)

HOPE. THOMAS, drawn and rendered from the wealthy family of the 'Hopes' of Amsterdam, and possessing with more than ordinary taste far more than ordinary means of cultivating and gratifying it, this gentleman established for himself an usefulness and reputation as a brother of a mere amateur and collector, since he did much in behalf of art, both with his pencil and his pen.

Mr. Hope, who was born about the year 1770, gave very precocious talents and a hand to the world, as in his childhood, a key of art which seems more than any other to depend upon acquired rather than natural and instinctive taste. 'From an infant,' as he himself tells us, 'architecture was always my
favorite amusement. I was scarcely able to hold a pencil, with which I copied all the faces, the figures, and all the other ob-
jects of which the imitation chiefly delighted the gen-
erosity of such children as show a turn for design, I already
began dealing in those straight lines which seem so little 
adorable in the hands of those who are acquainted with the 
thirty-fifth of a more advanced age. No sooner did I become master 
of myself, which unfortunately happened at the early age of 
eighteen, than dissuading any longer to ride my favourite 
hobby only in the confinement of a closet, I hastened in quest 
of food for it in all the different countries where any could be
expected. This valuable little scrap of autobiographical amply 
indemnifies us for the absence of more matter-of-fact account 
of his youth but sufficiently displays the author's sincerity and te-
teen, then, he went abroad, and remained there several years, 
occupied all the while very differently from most young men 
of fortune who visit other countries, for his passion for archi-
etecture induced him to explore regions that were then consid-
ered almost beyond the track of civilization—to study the 
monuments of Egypt on the banks of the Nile; those of Ionia, 
Northern Greece, the Peloponnese, and Sicily; those of the 
Tartar and Persian styles in Turkey and Syria; of the Moor-
ish and Arabian on the coasts of Africa and in Spain; those of 
the Etruscan, Lomardic styles, &c. in Italy; and finally, 
those of the Gothic, in France, Germany, Spain, Portugal, 
and afterwards here at home.

Eight years, he tells us, were thus occupied by him with a
persuasive application that would have daunted most profes-
sional men. From 1800 to 1809, he resided in Naples, 
tended with many fatigue and privations, and frequently with 
great risks.

Soon after his return to England he began to apply his
skilful taste and elegant execution to the decoration of 
Duchess Street, Portland Place, extending the plan of 
the original house very considerably by galleries carried round
three sides of the court-yard. Of these rooms, which are in
continuous order on the west, as many as fifteen, they consist of little more than five floors, the
largest one (about 100 feet by 24) is on the north side, 
and the others, consisting respectively of a suite of small cabi-
nets filled with Etruscan furniture and vases, on the east 
side, forms the gallery on the west. And in addition to these,
Mr. Hope added several years afterwards (1820) the Flemish 
Gallery, so called from being entirely occupied by
productions of that school. He thus rendered his house one
of the largest private mansions in the metropolis; and though
he did not bestow on it the slightest beauty of exterior or 
even any regard at all to appearance, he fitted up and furn-
ished the interior in a style of refined classical taste that was
then a decided novelty in this country. His first and memo-
rable publication on Household Furniture, in 1805 (a splen-
did folio volume with sixty plates exquisitely engraved in out-
tone), was the work which shows that his taste in furniture and decorations of his own mansion], created a revo-
lution in taste. But it also drew down upon him the mere-
less ridicule of the Edinburgh Review, which could not 
resist attacking at the gentler upholsterer. Yet, unless it be
perfectly indifferent whether good or bad taste be shown in such
matters, the reform in furniture of which Mr. Hope set the ex-
ample, and further promoted by that publication, was assuredly
a desirable one, and though there was a good deal of absurdity
and caricature in the ultra-classical effectation of vulgar and
parodying imitators, a very improved style of furniture—
one marked by greater simplicity and intrinsic beauty of form
has taken place and still prevails, where it has not been super-
seded by the tawdry frivolity of the Louis Quatorze and
other fashions.

In 1809 appeared his Costume of the Ancients, which had
already appeared in a prospectus of 1808. In promoting a taste for classical design and study; and in the same year he contributed to a periodical
(by J. Landseer) entitled Review of Publications of Art,
an essay on the Architecture of Theatres. Mr. Hope had
become somewhat less equal to his tasks; yet his books were
his guide, and his design his rule. In 1813, he published 
with his eldest son, J. Hope, a work on Household Furniture, which was
commissioned to execute his Jason for him in marble, now in the gallery in Duchess Street. But he
had been not always so fortunate as to select worthy objects of 
gastronomy, for in one occasion he bestowed it where it was altogether unmerited. Some dispute arising between
him and a French artist named Dobest, the latter
charged Mr. and Mrs. Hope, and announced under the title of 
"A Summary of His Works." As may be supposed, 
the affair, which occurred in 1810, made a very great noise at
the time, but the exhibition was soon brought to a close in a
very summary manner by Mrs. Hope's brother, who mari-
lized the picture and pronounced her the best 

painter of the day. This was not without effect, for the author, that it was at first consider-
ately attributed by many to Lord Byron, as the only person 
capable of having produced it; and certainly Mr. Hope's prev-
ious pursuits and publications were by no means of a kind 
to point it out as likely to be the author of a book of such

character. Of fiction. Of his two last works, both of them published posthumously, one of them was even still more remote from
what may be supposed to have been the constant temper of his studies, for that 'On the Origin and Prospects of Man'
was almost the very last subject that would have been ex-
pected from his pen: from furniture to cosmogony the dis-
tance is immeasurable. 

ology and literature of the United Kingdom: it is, however, a less mains head than the one painted by Lemuel Abbott, which was engraved by J. Heath in 1801. (Cunningham, Lives of British Painters, &c.; An Account of and descriptions in the Rooms of the British Institution, from 1813 to 1823.)

HORN. Mr. Arthur Aikin, in a paper on the manufacture of horn, tortoise-shell, and whalebone, read before the Royal Society, 1829, and published in the fifty-second volume of their 'Transactions' (part ii., pp. 334-349), observes that 'in the English language we have only one word to express two quite different substances, namely, the branched or double horn, or the scarified horn which is sometimes called the unguinated horn of the ox genus, and other kinded genera. Of the former kind, which are, with few exceptions, confined to the male sex, and which are reproduced annually, an account is given under Dama, P. C., p. 346. The uses to which they are applied are the same as those of bone and ivory, and the manufacture presents no point which requires notice. The other kind of horn, to which the French pronounce the same corne (while they apply the same bois to bony horns), is found in the ox, the antelope, and the goat and sheep kinds. Such horns, with the exception of those of the prongbuck [Antilocapra, P. C., n. 11], which are not referred to by Aikin, arc, he observes, 'never branched or palmed, but are always of a simple conical figure, more or less curved, and, in some of the antelopes, spirally twisted; they are found in both sexes and both kinds. The horns of the goat and sheep are much larger in the male than in the female.' In 'all these animals,' he adds, 'a bony core, of a loose texture and conical figure, rises from the bone of the forehead, covered by a permanent vessel, which, in the course of time, secretes thin layers of horn in constant successions.' It is supposed that one layer, or rather one set of layers, is produced every year; but, as the former layer remains closely adherent to the new one, such horns are permanent, lamellar in texture, and exfoliate only very slowly from the outside by exposure to weather and friction. The structure of such horns may therefore be described as a number of conical sheaths inserted into one another, the thickness of which membrane which covers the bony core. The tip, or that portion of the point of the horn which projects beyond the core, is very dense, and the several layers of which it is composed are scarcely distinguishable; while towards the base the layers may be readily distinguished, owing to their successive terminations forming prominent rings. The horn proper is quite insensible, so that the tip may be cut off without giving pain to the animal; but if the core be cut into, bleeding ensues, and it becomes evident that pain is inflicted. Horn appears to consist of coagulated albumen; and Aikin traces the connection between the substance of horns, nails, claws, and the bones of animals of the quadruped kind, lizards, serpents, and fishes, hair, feathers, and even skin. In the case of tortoise-shell and the armour, or covering shell, of the pangolin and armadillo, the identity of the material, in the form, and in some cases even in the character is sufficiently obvious; and the horns of the rhinoceros appear to form a link with the hairy covering of hoofed mammals generally, the bards of the boar tribe, and the spines of the needle-hog and porcupine. These horns are not formed upon a bony core, but are described as merely an aggregation of flattened hairs or bristles adhering by their sides, and presenting longitudinal pores or interstices of considerable magnitude at the base of the horn, and which become smaller towards the point, these interstices being, in the living animal, filled with a jelly matter. Whalebone, also [Rhinoceros, P. C., pp. 294, 295], is represented as illustrating the structure of a horn to hair; but its use in the arts differs much from those of horn. It is softened by boiling in water for some hours, and then cut into suitable lengths. It is used, to a great extent, its transverse division being effected by splitting, or separating its fibres. It is usually of a dark colour, but which appears jet black by dry. It is much used in the manufacture of caskets and curiosities, in stiffening and supporting other articles. The large quantity of female dropt in whale-making, and in various other ways. White whalebone is also manufactured into very elegant bonnets, and occasionally into artificial flowers of great delicacy and design, of which many are by dry. The principal kinds of horn employed in manufacturing operations are those of oxen, to which the hoofs of the same animals may be referred. The horns of bulls and cows are preferred, those of bullocks being thin and of a coarse texture; a circumstance which seems to indicate some connection between the sexual functions and the development of the horns, similar to that mentioned under Deka, P. C., p. 350. Our domestic supply being unequal to the demand, great quantities of horns are imported from other lands; and, the Cape of Good Hope, and South America. The horns of goats and sheep, according to Dr. Ure (Dictionary of Arts, &c. art. Horn), are to be preferred as whiter and more transparent than those of cattle, and less liable to injury from the sun or winter, according to Dr. Ure, by which operation the membrane which lies between the core and the bony sheath is so destroyed or softened by heat as to make it easily extracted. Those, Aikin observes, are not thrown away, but are burnt to ashes, in which state they form the best material for the small tests or cupples employed by assayers of gold and silver. In some cases, according to Balbigo (Economy of Machinery and Manufactures, p. 164), instead of being thus used, the cores are boiled down in water, by which a quantity of fat is extracted, which, rising to the surface, is skimmed off and sent to the makers of yellow soap; while the liquid itself is used as a kind of glue, and is purchased by cloth-dressers for stiffening; and the remaining insoluble substance is crushed in a bone-mill for making the horn powder by which ivory is made, and for a frame-saw, and is employed for making knife-handles, umbrella-handles, the tops of whips, buttons, and various other articles. The remainders of the horn, which is employed for purifying waxes, is thin lutes, which, when they are thrown out of the horn, are so short that they are not of much consequence, and are left entire, or sawn into two or more lengths, according to the use to which it is to be applied. When divided, the lower part, or that next the root of the horn, is frequently employed for making combs, while the portion which has formed the middle of the horn is used for lanterns and similar purposes. To prepare the horn for use, it is immersed in boiling water for about half an hour, by which it is softened; and, when hot, is placed upon the hot fire of a coal or wood fire, until it acquires the temperature of melting lead, and becomes so soft as to be malleable. If the horn be from an old animal, care must be taken to expose the inside as well as the outside to the action of the flame. Mr. James, of Lambeth, a worker in horn, was rewarded by the Society of Arts in 1827 for a machine for accomplishing this object much better than in the usual way. His apparatus, which is described in an article of the Society's 'Transactions,' p. 164, consists simply of a block of cast iron pierced with a conical hole, and a conical plug of the same metal, about one-eighth of an inch less in diameter than the hole, which is driven into the end of the fire to about the temperature of melting lead. The block is then taken out and placed on a firm support. A piece of horn, which, if intended to be spread out flat, should be previously boiled in a vessel covered with water, so that the water be not boiled so as to prevent the entrance of air, is put in the middle of the heated plug. It is then boiled out, and the horn, which is sufficiently soft to be opened out, is removed. This apparatus is said to effect considerable saving of time, in adding to avoiding all risk of overheating the horn. In the more ordinary process, as described by Aikin, the heat is applied before the horn is slit; the slitting being then performed in the semi-fluid state, by a strong pointed knife resembling a penknife, and, by the application of two pairs of pincers, one to each edge of the slit, the cylinder or cone of horn is opened until it is nearly flat. Several forms are then employed to pressure between alternate plates of iron, previously heated and greased, to prevent the horn adhering to them, either in a press, or by placing them vertically in a strong iron trough, and compressing them with water, then the pressure is increased or decreased by an engine, the pressure being regulated by leading the water applied depends on the intended use of the horn; if it be intended to form very thin leaves for making lanterns (or lantern-horns, as the word was formerly written, apparently with reference to the form of the prongs of the scissors), the pressure must be sufficiently strong to break the gristle, and cause the lamina of the horn to separate a little, so that the edge of a round-pointed knife may be inserted between them to complete the splitting or separation. The thin sheets of horns are then
HOR

47

escaped with a blunt or wire-edged draw-knife, upon a board covered with hull's hide, and when thus smoothed and brought to the required thickness, they are polished by a woollen rag dipped in the same. The smoothness is thereby brought to the palm of the hand. The painted toys known under the name of Chinese sensitive leaves, which possess the curious property of curling up if they were alive when laid upon a warm hand, or near a fire, are made of the horn of the tortoise; they are composed of the skin of this animal which is an essential ingredient in albumen, with the lead dissolved in the alkali, and thus introduced into the substance of the horn. Some other dyers are mentioned by Dr. Ure.

No part of the horn mentioned above possesses its value. When exposed to a decomposing heat in close vessels, horn produces a large quantity of the gaseous compound which forms the base of prussic acid, on which account hoofs and horns are employed in the manufacture of Prussian blue, and of the beautiful yellow prussiate of potash.

The clippings of the comb-maker are also used as manure. 'In the first year after they are spread over the soil,' observes Dalhage in the work above quoted, 'they have comparatively little effect, but during the next four or five years their efficiency is considerable.' The shavings of the lantern-maker, from their extremely thin and divided form, produce their full effect on the first crop.

Among the various uses to which horn has been applied, Aikin alludes to bows, both ancient and modern, made either entirely or partly of this material, and to armour. He had seen a complete suit of scale armour, which was said to come from Arabia, made entirely of horn. The employment of this substance for glazing windows has long been superseded by the use of glass.

HORNER, FRANCIS, was born, Aug. 12, 1778, in the city of Edinburgh, where his father was a merchant. He was educated at the High School of Edinburgh; in 1792 he matriculated at the University of Edinburgh, where he pursued his studies till the summer of 1795. He was then seventeen years of age, and being disposed to select the law as his profession, his father sent him to England, and placed him under the care of the Rev. John Hewlett, of Shacklewell, in Middlesex, in order that he might get rid of his Scottish dialect, and gain some experience among strangers, as he had hitherto constantly lived at home. He returned to Edinburgh in Nov. 1797, and, having fixed upon the Scottish bar as his profession, at the age of twenty he commenced his practice.

In 1802 Horner began to have thoughts of exchanging the Scottish for the English bar, and in April of that year he came to London in order to observe the regulations and practice of the law, and fix his determination. His friendships and political opinions had associated him with the rising Whigs in Edinburgh; he was now received with salacity by men of congenial opinions in London, by Mr. Abercorn, Sir James Mackintosh, Sir Samuel Romilly, and others. He resolved to attach himself to the English bar, and in the spring of 1803 he took up his permanent residence in London. It was an eventful and a thrilling time. The French war was again breaking out, the King's sanity was doubtful, and the Addington administration was giving way before the cross-firing of Pitt and Fox. Horner was not allowed to remain an unengaged spectator. As his abilities became more known, his connections with the leading Whigs were extended. On the death of Mr. Pitt in 1806 the government was placed in the hands of Lord Grenville and Mr. Fox. Horner accepted a seat in the Board of Commissioners established by the East India Company for settling the Nabob of Arcot's debts, an unalarmed office, which however was to be remunerated at the close of the investigation. On the 23rd of June, 1809, Lord Kinnaird, of a ministerial seat in the House of Commons, which, after consultation with his friends, was accepted, and in Nov. 1809, he was returned for the borough of Bedford. Fox had just formed the Whig party, which he had held together, immediately fell to pieces. A new parliament was summoned, and met on
the 16th of December. This parliament was very short-lived. A change of ministers took place on the 5th of March, 1807; premature in its character, and the bill proposed on the 29th of December immediately afterwards dissolved. Horner did not obtain a seat at the general election, but in the following July was elected for the borough of Westminister, as the interest of Lord Elgin and Mr. Carrington. He spoke little at first, on matters of business only, and briefly. By degrees he began to take a part in great questions. He entirely coincided with the Whig party in their condemnation of the course of the Spanish fleet; he voted from their shrinking policy on the question of the Spanish war. In May, 1809, he resigned his seat at the Board of Commissioners for investigating the debts of the Nabb of Spain, and was succeeded by Mr. Henry Bouverie. In a letter of existing in a short time, he was opposed too much with the pursuit of his profession. On the 1st of February, 1810, Horner made a motion for an inquiry into an alleged depreciation of bank notes. The subject was one which he had studied extensively, and he made a very decided impression on the House. He was appointed a member of the Bullion Committee, and by the which he took in, by his share in drawing up the report, and by his speeches on the question in the House, he acquired a solid reputation and a position and influence there which he afterwards rather augmented than diminished. On the Regency question he spoke on the side of his friends with great power and effect. In the negotiations for the formation of a ministry by Lord Grenville in 1811, Horner was offered the situation of one of the Secretaries of the Treasury, but he declined the offer. In the general election in 1812 he was not returned as a member, but by the intervening year, he was elected for St. Mary-le-bow, through the interest of the Marquess of Buckingham. In the sessions of 1813 and 1814 he took a prominent part in the debates, and became one of the acknowledged leaders of his party in the House. He supported the great scheme of the nanopneum, and made the tour of Genera and the north of Italy. In the great crisis arising from the return of Bonaparte from Elbe, when Lord Grenville urged the necessity of a war and Lord Castlereagh hesitated, the latter was convinced which the country seemed disposed to enter upon it, Mr. Horner supported Lord Grey, and the difference of opinion seemed to be so irreconcilable that he offered to surrender his seat, but the Marquess of Buckingham declined to accept his resignation. On the 25th of June, 1816, he made his last speech in parliament, in favour of the Catholic claims, and against the intolerant and harsh treatment which Ireland had experienced from the government of this country. Symptoms of a pulmonary disease had already begun to show themselves in his constitution, and he was advised by his physicians to spend the winter in the south of Europe. Accompanied by his brother, Mr. Leonard Horner, he set out on his journey, and arrived at Pisa in the latter part of November. His disease grew rapidly worse, but he had no suspicion that it was dangerous, and he continued to lay down the burdens for future studies with an exemption. On the 6th of February his difficulty of breathing came on with increased severity. He died on the 8th of February, 1817. His body was opened, and his com- pressions found to be, not consumption, but induration or hard matter of the lungs and enlargement of the air-cells to an extraordinary extent. He was buried in the Protestant cemetery at Leghorn, where a marble table-tomb was erected to his memory by his father. At one of the ends of the monument is a likeness of him in relief, of the size of life, by Chantrey. A marble statue of him, also by Chantrey, is placed in the north transept of Westminster Abbey, the cost of which was defrayed by subscription among his personal and political friends. It is one of Chantrey's best works, and indeed one of the finest portrait-statues in the Abbey.

The character of Horner's understanding was that of vigorous and acute, but the subject of imperfect health. He had no wit, and made no pretence to any. His knowledge was extensive, and his judgment accurate, not only in the various branches of political economy, but in a great many other departments of science. He was one of the editors of the Edinburgh Review, and wrote many articles for it. As a public man his independence was unquestionable; his integrity, sincerity, and moderation were acknowledged by his party. He was a man of great observation, and equally free from any kind of affection or any trace of rancour. As a public speaker he was grave and foreboding, without imagery or any of the accessory ornaments, but with an earnestness and evident sincerity of manner which produced an effect greater than he could have done by any appeals to the imagination or the passions.

(Memoirs and Correspondence of Francis Horner, M.P., edited by his brother, Leonard Horner, Esq., F.R.S.; Querries of the 20th of April, and was)

HOROLOGY. A general notice of the history of the chief peculiarities in the construction of the principal kinds of clock and watch. First published in the Gentleman's Magazine in P. C. p. 297; and under Chronometre, P. C. p. 134; JEWELLING of WATCHES, P. C. p. 117; Pendulum, P. C. p. 402; and Watch, Repating, P. C. p. 107, are further and more particular particulars. The principal object of this article is to supply information respecting some important modern improvements in the construction of the large clocks used in church-towers and public buildings, the names of which are generally known by the name of church or turret clocks.

Turret-clocks differ from other machines employed for measuring time, not only in their greatly superior size, but also in the arrangement of their parts, and in the circumstance that they are usually made to strike the hours, and often the quarters also, upon large bells, and are occasionally connected with machinery for chiming whole tunes at certain intervals under a set of bells which, when mounted in a church-tower, are so hung, that by disconnecting the hammers of the chimes and striking apparatus, they may also be rung in the ordinary manner by means of ropes. A popular description of the mechanism of such a clock is given in a paper in the 'Penny Magazine' for 1842 (No. 641), describing a visit to a church-clock factory and bell-foundry, which is illustrated by a representation of the clock of St. Anne's Church, Limehouse, with a large turret-clock in the churchyard. The clock consists in the circumstance that it is frequently required to indicate the time upon as many as four different dials, on the four external faces of the tower in which it is mounted. This apparatus is usually enclosed in a primitive and beautiful manner, by placing the clock in or near the centre of an apartment either on a level with the external faces, or above or below them, and causing the motion of the axis which under ordinary circumstances would carry the minute-hand (which revolves once an hour), to be transmitted by bevil-wheel to a vertical rod, the opposite end of which carries a horizontal wheel-wheel nearly on a level with, and situated centrically with reference to, the four external dials. The motion of this central wheel is communicated, by four vertical bevel-wheels of the same size and number of teeth, ranged round its circumference, to four horizontal rods, the opposite ends of which, passing through the several dials, carry the four minute-hands. At the back of each dial is a series of wheels and pinions, technically called the motion-work, precisely resembling that described in the vertical watch under HOROLOGY, P. C. p. 302, by which motion is imparted to the hour-hand, which revolves once in twelve hours. As in the case of the eight-days' spring clock, described in the preceding article, the weights and the striking apparatus are provided for by separate trains of wheel-work, each of which is impelled by its own moving power. In a turret-clock, the moving power is supplied by a huge clock-work of the moving or going-train, by the oscillations of a large pendulum, and in that of the striking-train by the resistance of the air to the rapid revolutions of a fly or fan set in motion by the wheelwork. In the arrangement of these trains, and in their connection with each other, there is nothing which requires special notice here, as these matters may be readily understood from the account of a spring-clock above referred to. Owing to the necessity for using a very heavy hammer to strike the hours in a church-tower, the power required for working the striking-train considerably exceeds that of the going-train. In the Limehouse clock above referred to, the going weight is about 1600 pounds, and the striking weight is about five hundred pounds. These weights are wound up in most cases, weekly, by means of which handles and toothed wheels connected with the massive drums round which their ropes are wound are raised by means of a coiled spring or the clockwork of the going train. The striking clock is independent of the going-train by its striking apparatus being directed by guide-pulleys. In this clock the pendulum, which is motioned with a large clock, is about fifteen feet long, is about fourteen or fifteen feet long, is about of weight, being of a mass of cast iron shaped like a double convex lens, about thirty inches in circumference and weighing about two hundred pounds. Each of the four clock-faces is fitted for the striking of hours by each pair of hands weights about sixty pounds; but as the hands are very nicely balanced by weights attached to the
extremity opposite to the pointed end, the power required for moving them is much less than might be supposed. In some turret-clocks, indeed, the small size of the going-train and of the apparatus by which motion is communicated to the hands appears strangely disproportionate to the magnitude of the dial. In the Linthwaite clock, the beam of the hammer by which the hours are struck weighs fifty-six pounds, and it is set in motion by the apparatus represented in Fig. 1, which may serve as an example of the striking mechanism of turret-clocks in general, although the details of course vary according to the relative situation of the clock and the bell, which, in some cases, is the reverse of that here represented: the bell being above, instead of beneath the level of the clock itself.

![Fig. 1](image)

In this cut a represents the pin-wheel, corresponding to the wheel f in the striking-train of the clock represented in Horolog. P. C., p. 300, Fig. 1, by the action of the projecting pins of which upon the end of the lever b, communicated through the levers c and e, the tail f of the hammer is depressed, and the hammer-head is consequently raised ready for a stroke. By the continued revolution of a, the end of the lever b, after being raised to a considerable height, is suddenly released, by which the hammer falls upon the rim of the bell, and the connecting apparatus resumes its original position ready for the next stroke. It must be borne in mind that the rod or wire d by which the levers c and e are connected, is here represented much too short. In ordinary cases, it is of sufficient length to reach from one story of the tower to another.

Musical chimes, which form a pleasing though not very common addition to the mechanism of turret-clocks, require the addition of another train of mechanism, somewhat like to that which constitutes the striking-train, inasmuch as, like it, it is perfectly at rest for considerable periods of time, and is brought into action only at certain predetermined intervals by the action of the going-train of the clock upon a deton. The mechanism of the chimes very nearly resembles, on a large scale, that of a musical snuff-box; levers connected with hammers which strike upon a series of bells, being substituted for the springs which in the musical snuff-box are caused to vibrate by the projecting pins on the revolving barrel. Beautiful machinery has been introduced to facilitate the accurate pricking of the barrel, or insertion in their proper places of the pins which project from its surface; but the principle by which the operation is regulated may be sufficiently explained by an account of the old method of performing it. A sheet of paper exactly equal in size to the surface of the barrel, and which, therefore, would completely cover it if wrapped round its circumference, was ruled in a direction perpendicular to, or at right angles with, the axis of the barrel, with as many parallel and equidistant lines as there are different notes in the tune to be performed, each of these lines indicating the position of one of the series of levers worked by the hand on each of these lines was marked the name of the note represented by it. This series of lines was then crossed by another series lying parallel with the axis of the barrel, which divided the circumference of the barrel into as many equal parts as there are bars or equal divisions of time in the tune. These spaces being then subdivided by other lines, according to the number of minutes, or quarternotes in the required tune, the required tune were marked by ink dots upon the paper on their respective lines and in the order of time in which they should be produced, as regulated by the bar-lines and by the subdivisions of the time of each dot. The dots are then transferred upon the barrel, and the pins were inserted at the points indicated by the marks on the paper. This comparatively rude and simple process, though in which each bar is made, by shifting a little longitudinally upon its axis, to perform several tunes, indicates the principle common to the pricked barrels of chimes, musical snuff-boxes, and barrel- organs.

Owing to the very limited demand for turret-clocks, and their great durability when well made and carefully preserved, the business of making them is confined to very few establishments, and has hardly been systematized into a manufacture, in the more definite sense of that term. Every clock being, in ordinary cases, made individually, and with comparatively little aid from machinery, turret-clocks have been very expensive, and in many cases inferior in every respect, to many far simpler cheaper and more common machines, in the manufacture of which more extensive use is made of the lathe, slide-rest, planing-machine, and other contrivances for shortening labour, and raising a higher degree of precision, than could be secured by hand-labour. Mr. Dent, who had previously succeeded, in the face of much prejudice and opposition, in remedying a similar defect in the manufacture of chronometers, determined, when engaged by the Graham Committee to make a turret-clock of unprecedented perfection for the new Royal Exchange, under the superintendence of Mr. Airy, the astronomer royal, to meet this deficiency by establishing a clock-factory supplied with the latest aids and appliances of modern ingenuity, in which the several parts of a turret-clock should be produced as far as possible in the same way as the component parts of a power-loom, and other machine manufactured upon an extensive scale. By such a judicious outlay of capital it becomes easy, having once made the required models, to produce as many clocks as may be desired, the component parts of which are perfectly of the same kind and quality, and which, while finished in a very superior manner, can be supplied at a cost greatly below that of what may be termed hand-made clocks. In the manufacture of smaller clocks and other horological machines, for which there is a more extensive demand, the application of manufacturing principles is even more important; and we may express a hope that the prejudices which have hitherto stood in the way of such improvements, and restrained the application of capital to this branch of ingenuity, are giving way. When the gentleman referred to above first introduced the use of the slide-rest in the manufacture of turret-clocks, his machines were found to be, in consequence of the justice of the theory, inferior to those employed by them, so continually out of order that he was compelled to call in the assistance of engineers to repair and work them; but now the clockmakers and engineers work together in the most cordial manner, and with the most satisfactory result.

One of the first points which would strike an observer in the Exchange clock, and in other turret clocks made on the same principle, is the use of a simple but strong cast-iron framing, in which every strain is so completely self-contained that the operation of fixing the clock in its destined position is one requiring but little skill; scarcely any of the being required beyond the fixing of the frame on a firm and level base. Another, and a more unusual feature, which Mr. Dent has introduced into the turret-clock manufacture, although it is not adopted in the Exchange clock, is the use of cast-iron wheels for the striking train, which is considerably larger than the going train. This peculiarity, which will be of great advantage, not only on account of the superior durability of the metal, but also as tending greatly to reduce the cost of the clock, is not claimed as an invention by Mr. Dent, such wheels having been, according to information with which he has favoured the writer, used in France for forty years past. In some Exchange clocks, with many other turret clocks of the same authority, wheels of wrought iron were used, but the teeth of these bad to be cut in the same manner as those which have been described, and which are used for the purpose, while those of the cast-iron wheels are formed by the casting operation alone, from an accurate model. The wheels of the going train, which are not only smaller but require greater accuracy from the circumstances that any imperfection in their

P. C. S., No. 92.
action would impair the correctness of the clock, which is not the case with the striking train, are best made of hammerd brass, which is a material more to be depended upon than gunmetal. The wheels of both trains are formed with teeth of a peculiar shape, on the subject of which Mr. Dent presented a paper before the Royal Academy in November, 1844, in which he states that the geometrical form of the wheel-teeth in chronometers, watches, and clocks is seldom attended to by the persons who either cut the wheels or make the pinions; which he thinks may be explained from the circumstance that these operations are being separated into two distinct trades. The system pursued by watchmen to insure what they suppose to be the proper form of the wheel-teeth is, he observes, the style of polygon (the driven) the hypcycloidal curve, putting nearly the whole of the curve on the wheel-teeth, increasing the circumference beyond the geometrical circle, by the addition of three teeth and spaces, allowing only 0.5 of the circumference of the pinion, just to remove the possibility of any sharp edge. In every case the curvilinear curve has been described by rolling the semi-diameter of the driven on the geometrical circle of the before named, the curves of the tooth of the pinion, and the teeth of the pinion; the latter should be cut for the purpose of ascertaining the breadth that the wheel-teeth should be in excess above those of the pinion-leaves; for as the breadth of the wheel-teeth is increased, the errors of the pinion are increased, the teeth driving before and after the line of centres is varied. Mr. Dent has also applied this theory to the lifting of the hammer, both for the striking apparatus and the chimes, by using polygonal, hypcycloidal shape instead of the ordinary round pins in the pin-wheel.

Among the other important features of the Royal Exchange clock, which are applicable to all others of similar character, whether constructed with its peculiar contrivances for insuring perfect accuracy or not, we may mention the use of hollow iron drums instead of wooden cylinders for the driving barrels, and the use of wire instead of hemp ropes for suspending the weights. The firstmentioned of these improvements renders permanent accuracy of form more attainable, while the latter obviates, in consequence of the much smaller size of the barrel, the necessity for overlying the length of rope may be collared in a single layer upon the barrel without increasing its length or diameter in an inconvenient degree. The result is that the weight continually exerts the same force upon the barrel, while covering the barrel in two or three layers, its effective force is of necessity greater at the commencement of its descent, when it acts upon the circumference of the barrel plus the thickness of the first or innermost layer of rope, than at the latter part of its descent, when it acts on the circumference of the barrel alone. Another important arrangement, which, though formerly in use, has been departed from, and is revived in this clock, is the driving of the hands of the clock, and the raising of the hammers of the striking apparatus directly from the axis of the driving-barrel, without the intervention of any wheels and pinions.

A peculiarity that has hitherto been a public clock of unexampled accuracy, the Graham Committee required that the Exchange clock should have a compensation-pendulum, and the operation is introduced as one of the important steps to show permanent correctness time upon the dial, but also to tell it with accuracy by noting the first stroke of the hour upon the bell true to a second. This degree of precision is unattainable with the ordinary striking-apparatus, as the effect of variations in the state of the atmosphere upon the motion of the fly by which its action is regulated, and of various circumstances affecting the inertia of the machinery to be brought into motion, together with the slight variations in the pressure of the hammer upon the lever by which the hammer is moved will become disengaged from the pin or tooth of the pin-wheel by which it is raised or depressed, render it impossible to adjust the mechanism with certainty to produce such a result. In the Exchange clock this difficulty is provided for by an arrangement for moving the lever and hammer nearly to the position it occupied before the time of striking, and causing the end of the lever, which is formed in a peculiar manner for the purpose, to remain poised delicately upon the rounded point of the projection or hook which projects from the pendulum, and which, when it is instantaneously released, and thus the stroke is produced without being affected by the preliminary operation of raising the hammer.

The principle upon which pendulums are provided with compensations for changes of temperature are explained under Pendulum, P. C., pp. 402, 403. That of the Exchange clock is of a comparatively simple construction, which appears well adapted for this purpose, as near as the pendulum is of steel, and is sufficiently long to pass completely through the bob or weight, which, however, is not immediately attached to it. Upon the bottom of this rod is fixed a nut, by turning which the length of the pendulum may be readily adjusted, and upon which stands a hollow or taperular column of zinc, through which the steel rod passes freely. On the top of the zinc column is a metal hop, from projecting portions of which descend two slender steel rods, to the lower ends of which the weight, which is a hollow cylinder of iron, capable of sliding freely upon the zinc column, is suspended. Thus, when the temperature of the steel rod and the two smaller steel rods by which the weight is suspended, expands downwards upon any increase of heat, the position of the weight in reference to the point of suspension of the pendulum is not materially affected, though shorter than the central steel rod, expands, owing to the different nature of the metal, to an equal extent upwards, and consequently raises the weight just as much as it is proportioned to its length. The weight is supported upon a point in the central portion of the zinc column, which in consequence of pendulum. The action and cock, which in consequence of the striking mechanism, which is described and illustrated under Pendulum, P. C., has the mercury in a glass jar, the fragility of which not only exposes it to the risk of fracture, but also renders it unsafe to boil the mercury after filling it, to drive off the air which it always contains. Further than this, while it is possible to give, externally, a mathematically correct form to a glass jar, the interior cannot be made of a perfect figure, and consequently the column of mercury which it contains cannot be a perfectly regular cylinder. 'This condition,' Mr. Dent observes, 'combined with the irregularity of expansion which glass is known to exhibit, may be remedied by the employment of a suitable substance for the compensating measure of the pendulum, and in addition, in order to render the measurement and calculation, with regard to the column, so vague and deceptive that they are never employed.' These defects have been removed by substituting a jar or cylinder of cast iron, which is known to expand much more than glass, and moreover as it is with glass, for the ordinary glass jar. This material may be brought with the utmost accuracy into the required form, and although the sects of expansion and contraction, the figure of the vessel is not perfectly permanent and unchangeable, its changes are of a nature which is well understood, and may be calculated upon with accuracy. In such a case, it is necessary to put in the tube at the proper time. 'The clock-maker may do it himself on the first putting of the machine together,—may adjust the column,—may then hermetically seal it, and dispatch the pendulum to the most distant countries with the adjustment so perfect that
it may be instantly attached to the wheel-work by any workman capable of coping with a clock, and which, at any subsequent period, minute portions of air have, from any cause, again mingled with the mercury, and rendered the pendulum susceptible of barometric changes, the air may again be expelled at the greatest facility with the least chance of the process of boiling, without removing the mercury from the case.

In connection with this improvement Mr. Dent has introduced some other alterations in the construction of the mercurial pendulum, among which is the attachment of the cistern directly to the pendulum-rod, and consequent removal of the metal stirrup or frame formerly used to carry it, and the prolongation of the rod so as to plunge its lower end into the mercury. It is fastened to the bottom of the case, in an arrangement favourable to uniformity of temperature in the rod and mercury; and since the date of the paper we have quoted, he has, with a view to obtaining additional precision in the performance of the astronomical clock, taken out a patent for giving impulse to the pendulum at, as nearly as can be determined, the centre of percussion. In this arrangement, the pendulum, instead of being suspended below the clock, is suspended from a fixed point at the top of the clock-case, while the clock itself is at the bottom, the only connection between the two being effected by momentary contact, at the extremities of the range of the pendulum's vibration, with two slender pins attached to the escapement. 'In this old arrangement,' the inventor observes in his published Abstract from Two Lectures on the Construction and Management of Clocks, Watches, and Chronometers delivered before the members of the United Service Institution, May, 1841,' the pendulum never vibrates independently of the mechanism of the clock; besides which, the impulse is given under very disadvantageous circumstances, as the greater part of the force communicated by the escapement is lost at the point of suspension. In his patent astronomical clock, with the detached pendulum, these defects are in a great measure remedied, for he states that 'if the pendulum vibrates two degrees from the perpendicular, one degree and forty-five minutes will be entirely detached from the mechanism, and the irregularities occasioned by friction and other disturbing causes are avoided entirely.'

Returning to the turret-clock at the Royal Exchange, in which the connection of the pendulum with the wheel-work is of the more ordinary nature, the escapement is the next point which claims notice, though it is too complicated to be fully described without several figures. Its chief peculiarity is that it is of the remontoire kind, a circumstance in which it resembles some of the best public clocks in France; among others, that of the Bourse at Paris. To explain this it may be sufficient to state that the impulses imparted to the pendulum are not given immediately from the large going-wheel of the clock, which is exposed to variations of force and resistance from the resistances of the escapement friction, the oil, and the like, by way of lubricating the mechanism (the use of which, however, is limited to the least possible degree), and from the effect of the wind upon the large hands of the four external dials, which in the case of a turret clock is a variable force; but is provided with a small secondary train, set in motion by the descent of a ball or weight, which is itself raised at intervals of twenty seconds by the mechanism of the going-train. The action is therefore very similar to that of a remontoire-spring, which, as used in some horological machines, is a small spring employed only to set the escapement in motion, it being itself wound up at very short intervals by the going-train, which receives its impulse from the prime mover. Such a contrivance favours accuracy of performance by detaching the escapement, by which the velocity of the machine is determined, or, in other words, by which the measurement of time is affected, from the power, necessarily subject to some irregularities, by which the greater part of the machinery is kept in motion, whether that power be supplied by a weight or a spring. To prevent the backlash of the brass teeth of the dead-beat escapement, and has the pallet jewelled with large sapphires; but in his ordinary turret-clocks Mr. Dent uses a modification of Leparte's escapement, over a single pin. In an early clock he introduced a contrivance for maintaining the motion of the wheels during the time of winding up, which was invented a few years since by Mr. Atry for the clock-work of the great Northumberland telescope at the university of Oxford; and he describes it in a publication made by request from the Cambridge Philosophical Society, vol. vii. part ii. p. 217. Harrison's beautiful contrivance of the going-fusee, of which a description is given under Horology, P. C., p. 301, is not sufficiently powerful for application to large clocks, in which the strain of very heavy weights has to be provided for; but Mr. Airy's contrivance, which he describes as 'a new construction of the going-fusee,' supplies the deficiency. Its action will be understood from the annexed diagram, Fig. 3, which represents one of several forms of the apparatus shown in the illustrations of Mr. Airy's paper. In this diagram a represents the first wheel of the clock, which is mounted, as usual, upon the axis of the rope-barrel &b, with a ratchet and click so arranged that the two must turn together whenever the rope-barrel is turned, by the action of the weight W, through the line l, in the direction indicated by the arrow; while, when the rope-barrel is turned in the opposite direction, to wind up the weight, by the action of a windlass on the axis of the wheel d, which engages the toothed wheel e on the axis of the barrel, the wheel a will not turn back with the barrel. f is the pinion which is turned immediately by connection with the first wheel a; and both this and the winding-wheel, or pinion, d, have their axes mounted in the plates of the clock-frame. The axis of the barrel and first wheel a, instead of being thus mounted, is attached to what may be termed a lever-frame, one side of which is seen in the cut at g, h, i, which is itself pivoted to the clock-plate at h, and to the end of which the end of the line l, j, is attached, after passing under a running pulley attached to the weight W. e is an internal ratchet on the first wheel a, acted upon by the long click m, which has its opposite end attached to the lever-frame near its extremity i. While the clock is going in the ordinary way the descent of W causes that part of the line marked f to be in the barrel in the direction of the arrow, carrying with it the first wheel a, the internal ratchet of which slips under, without being affected by, the click m. Under these circumstances the action of the weight W (through the line f), and the resistance of the pinion j, produce a certain pressure on the lever-frame at g, which causes the end l to assume a determinate position, in which it remains without motion so long as the weight continues to descend, and consequently to draw down the line i; but so soon as, by the operation of winding up the clock, the pressure upon j ceases to operate, the stress of the weight upon the portion of the line marked a, which turns as it were in one piece with the lever-frame round the axis h, thereby producing a pressure upon the pinion j exactly corresponding, if the axis h corresponds with the point at which the strain of the line l is applied to the rope-barrel, in the pressure which is exerted during the ordinary action of the machine.

The machinery connected with the Exchange clock for chiming tones upon a set of large bells in the turret has been constructed by the same general plan as the mechanism of the clock itself; but, owing to difficulties in the tuning of the bells, it is not yet (Nov. 1846) brought into action. These chimes will be the first constructed in this country to play tunes in
H. O. W. H. O. W.

harmly, two or more notes being struck simultaneously upon different hells, whereas in most cases the melody is produced in single notes, without the introduction of chords, which not only requires the machinery to be more complex, but renders it necessary to bring the hells into more perfect tune than is necessary in singing.

**HORSE-RADISH.** [Courgeta Armorica, P. C. S.]

**HORSE-SHOE.** [Horse, P. C. S.]

**HOSPITALS.** [Templars, P. C. S.]

**HOTTONIA,** a genus of plants belonging to the natural order Primulaceae. It has a 5-parted calyx, divided almost to its base, the stamens, 5, inserted and included in the tube of the corolla; the capsules many-seeded and 5-valved, with 10 teeth. *H. palearis* has the flowers whorled, stalked, and seated upon a long solitary cylindrical cymose peduncle, the corolla longer than the calyx, the leaves pinnate. It is a native of Great Britain in ponds and ditches, and is called the Water-Violet. The leaves are submerged and crowded; the flowers rising above the water are of a purple and yellow color. It is a pretty plant, but possesses no useful available properties.

(Fishingman, Manual of British Botany.)

**HOUBRACKEN,** the name of two distinguished Dutch artists in London.

**Arnold Houbraken,** the father, was born of a good family at Dort, in 1660, and was the pupil of Samuel van Hooegeest. He painted history and portrait, and executed many buildings. He retired with his family to Amsterdam; and he visited this country and remained here eight or nine months, for the purpose of making drawings of some portraits by Vandyke, which were engraved by Van Gunst. He left some papers, chiefly notes for his account of the lives of Dutch painters, with portraits engraved by his son, in continuation of Van Mander—"Grote Schouwburg der Nederlandische Konstschilders en Skilders," in three parts. The first two parts of this series were published at Amsterdam in 1718 and 1719, for the author; the third part was published in 1721 for his widow: Houbraken died in 1719.

**Jacob Houbraken,** an admirable engraver; in execution of his own designs, and even some designs of others. He was born at Dort in 1698, and accompanied his father when very young to Amsterdam. The excellent etched portraits of painters in his father's "Grote Schouwburg" are among his earliest works, yet they are certainly some of the finest etchings in existence. The most beautiful specimens, however, of Houbraken's engravings are some of "The Heads of Illustrious Persons of Great Britain," published in London by the Knights in 1748; the excellence of some of these heads must be seen to be comprehended.

**Veree** was a good engraver, and executed a few of the heads in this collection; but his inferiority to Houbraken was so apparent, that he did not possess so much confidence on his engraving. Some of the heads, however, which were engraved by Houbraken, though of the highest excellence as works of art, want authenticity as portraits, as, for instance, those of CARR, Earl of Northumberland, and S. W. T. Secretary. The excellence of some of the Specimens of this series is so great, that they are surpassing. [Veree, GEORGS, P. C. S.]

The collection is notwithstanding of great historical interest. Houbraken engraved also a great number of portraits of distinguished Dutch characters. He died in 1780.

**HOUSE.** [Horse, P. C. S.] A general outline of the principal features in the construction of houses being given under Building, P. C. S., and in the various articles in P. C. and P. C. S. which are referred to under that head, the sole object of this article is to supply one of the articles of the series there pointed out, which, in consequence of an accident, was unavoidably omitted under its proper title, *Floors*.

A floor of a single story is sometimes applied, collectively, to all the apartments and passages in a house upon one and the same level, in which sense it is almost synonymous with story. In a more literal sense however the term is limited to the horizontal side of such apartments, and the under surface of which either constitutes or supports the upper horizontal side, or ceiling, of the apartments of the story immediately beneath it. We must understand the floor to be the principal support of the floor, the internal or partition walls should be made to bear their share of the weight and strain; and where, as in the case of shops, warehouses, and public build-

\[\text{ings, partition walls cannot be allowed, the support of the upper floors, supposing the span to be too great for being sustained by the external walls alone, may be assisted by means of brick piers or iron columns. Where, owing to the subdivision of the upper stories into smaller rooms than the lower story partitions are framed without support from beneath, they may, as explained under } \text{Carpentry}, \text{ P. C. S., p. 233, not only be so constructed as not to throw any weight upon the floor, but, if necessary, so as to assist in supporting.}]

An ordinary wooden floor may be considered as consisting of two distinct parts: the actual flooring, or platform of boards laid upon the floor joists, which are framed either horizontally or on an angle, and are commonly called the naked or cassar floor, upon which the boards are laid, and which may be constructed in various ways, according to the strength required, and the span or width of the area to be covered. The simplest, and, under ordinary circumstances, the strongest kind of cassar flooring, or, as it is sometimes called, floor of joists, is that known among carpenters as a single framed floor, or, according to some writers, single flooring, which consists of a single row or horizontal tier of timbers called joists, or, more specifically, floor of joists, which, in order to dispose their strength in the most efficient manner, are made much deeper below the centres of the floor-joists than the ends which bear upon the sub-floor or walls, or in some cases, where the walls are too far apart, upon stout beams called girders, which may be strengthened by trussing. To the upper edges of these joists the flooring-boards, or, as they are called, flooring-tubs, are laid by their longer edges supported by the wall on which the ceiling of the room beneath is formed. The ends of the joists rest upon timbers loft into the wall, called wall-plates (Built- plate, P. C. S.), and against which they are equally distributed along the wall; the connection between the joists and the wall-plates being formed by cogging or cocking; or, as it is sometimes termed, encaust or encaulking, as illustrated under Black, P. C. S. In the ground floor of in inferior buildings, the ends of the joists are laid immediately upon the brickwork, without the intervention of wall-plates; but such a practice is highly reprehensible, as it not only leaves these ends of the joists unsupported, but permits them to be laid directly beneath the planks, to the exclusion of those on each side, but also prevents that evenness and solidity of bearing which is necessarily to keep the joists to a true level, that the pressure of the flooring-boards upon them may be uniform. Joists for a single framed floor should never be less than about two inches thick or wide, because of their liability to splitting with the operation of nailing down the boards, nor should they be much more, because, as will be better understood from *Plastering, P. C. S.,* any increase in the width of their under edges interferes with the key or hold of the plaster, which arises from its passing up between, and swelling over, the ends of the laths. In laying the flooring-boards, if they are used, narrow fillets may be nailed along their lower edges to receive the laths, instead of nailing the laths immediately to the joists. Such fillets are called *furrings,* and their application is of the utmost importance to the abovementioned purpose of rendering the ceiling perfectly flat, which a floor of joists never is, especially upon its under surface, owing to the roughness and warping of the timbers, is termed *furring down.* Furring-up is the contrary operation of laying slips on the upper edges of such joists as may happen to be below the proper level, in order to produce a perfectly horizontal bed for the flooring-boards. The depth of the joists, and their distance apart, may be varied according to circumstances, the former ranging from about nine inches to fifteen, and the latter being usually twelve inches, though a distance of twelve inches from centre to centre, leaving an interval of about twelve inches, is to be preferred. The strength of such a floor may be increased to any degree by increasing the depth of the joists and diminishing the intervals between them.

The best method of preventing warping of the floor, by which the strength of the floor would be greatly impaired, is guarded against by the introduction between them of small diagonal struts or braces, as represented in the cut Fig. 2, in a subsequent section, and crossing the staves, which are placed in rows extending completely across the width of the floor, at right angles with the direction of the joists, and at intervals of not more than five or six feet. These struts are not commonly necessary, but, if the joists are short, their effect would be increased by either nothing the joists to give them a proper bearing, or, without cutting into the joists, by nailing triangular fillets to them to afford abutments
for the struts. In some cases solid pieces of wood cut to fit the intervals between the joists are used instead of diagonal, or, as it is sometimes called, herring-bone strutting; and, whatever be the name, the strength imparted by it is not only increased where the floor will have to bear great weight to make the struts approximate very slightly to the wedge-shaped form of the voussoirs of an arch, in which case the floor may, by the addition of iron through without piercing the joists, rather below the middle of their depth, be forced up into a convex form, whereby its strength will be enormously increased.

When a timber floor is carried near to a chimney or fire-place it will be necessary to strengthen even such floors, as it is advisable in every case where the floor will have to bear great weight to make the struts approximate very slightly to the wedge-shaped form of the voussoirs of an arch, in which case the floor may, by the addition of iron through without piercing the joists, rather below the middle of their depth, be forced up into a convex form, whereby its strength will be enormously increased. In such a situation the carpenter has recourse to what is termed trimming, which may be understood from the subjoined ground-plan of part of a floor of joists, shutting against a wall in which is a fireplace with chimney-flues in the jamb. In this cut, a, a are two of the ordinary joints, the ends of which are supported in the

Fig. 1.

usual way upon wall-plates; b, b are two joints made somewhat thicker than the rest, on account of the extra strain thrown upon them, and called trimming-joists; c is a piece of timber called a trimmer or trimming-joint, the ends of which are formed into tusk-tenons, which pass completely through the trimming-joists, and are secured by keying or wedging in such a way as to prevent them from separating; and d, d are the trimmed joints, or those which, being cut off short of the wall, have their ends supported by being framed into the trimmer. The stone slab in front of the fire-place is supported over the space between the trimmer and trimming-joists by a flat brick arch, sometimes called a brick trimmer, turned between the wall on one side, and a piece of wood called a springing-piece, which answers the purpose of what engineers term a skew-back, attached to the trimmer, on the other side. When the direction of the joints is parallel to that of the wall in which the chimney is formed, the arrangement is of course somewhat different; one strong trimming-joint then takes the place of the trimmer c, and two short trimmers are put in the place of b, b.

The chief objection to the use of single flooring are, that the construction offers little obstruction to the transmission of sound from one room to another, and, for the sake of the ceiling, the joints must be made thin. Both of these defects may be in some measure overcome by the arrangement shown in Fig. 2, in which every third or fourth joint is made an inch

Fig. 2.

or an inch and a half deeper than the rest, and a series of slight bars called ceiling-joists, of which is shown in the cut at a, is nailed, or notched and nailed, to these deeper joints, so as not to touch the intermediate joints, and to these the ceiling laths are nailed. By this arrangement the joints may be made of any required thickness, and the ceiling is in a great degree relieved from the injurious vibration of the floor; and the effect of the shrinkage of the joints, which would cause the ceiling to crack.

In a double, or more properly a double-framed floor, three sets or tiers of joints are used, of which the middle set, called binding-joists, or simply binders, form the real support. These reach from wall to wall, or from one primary point of support to another, at intervals which may vary according to a rack of circumstances, but are usually about six feet; and they are surmounted, at right angles with their own direction, by a series of smaller joints, called bridging-joists, which may, if necessary, be notched on to them, and upon which the flooring-boards are laid. Beneath the

binding-joists is a set of yet smaller ceiling-joists, similar to those in the construction illustrated by Fig. 2. If it be necessary to save depth in fixing these also, care must be taken not only the ceiling joists to be notched only in the edges nearest to the header, but also that in every case the height of the binding-joists (or of the flooring-joists in a single floor) are always in a state of tension, and therefore cannot be cut at any angle incurving the floor; and, while those towards the upper edge of the binding-joists are in the opposite state of compression, and may consequently be cut without danger, provided that the notches made in them are filled with an incompressible substance. As a floor, when well season, is more compressible laterally than longitudinally, or across than along the grain, it is obviously better to avoid cutting into even the upper edge of the binders, because the bridging-joist, though it may fit the notch in the binder very tightly, will inevitably be more liable to compression than the portion of the binder which is cut away to receive it. Sometimes the ceiling-joists, instead of being fastened underneath the binders, are cut into short lengths and fixed between them, with only a sufficient degree of projection below them to keep the ceiling clear of the binders. Some builders, in such a case, mortise the ceiling-joists into the binders, employing a chase-mortice at one end to allow the ceiling-joist to be slipped laterally into its place after the binders are fixed; but as the mortar cannot fail to weaken the binders, it is far better to nail projecting slips within the lower edges of the binders, and to note the ends of the ceiling-joists so as to fit on to, and to be supported by them. In either plan it is necessary to nail small pieces of wood beneath the binders to prevent the edges of the joint in the ends of the binders from being exposed to the open air, in order that the hold for the laths may not be interrupted. Bridging-joists must be distinguished from the short pieces of timber called bridgings which are fitted between the joints when a quarter partition is to be put up against them, to support and afford facilities for nailing down the sill of the partition.

In floors of great span, girders, which are large beams usually supported by columns let into the walls [Building, P. C. S., p. 248], or by iron columns, are used in conjunction with bridging, binding, and ceiling joists. Girders, which are used for longer beamings or spans than bending-joists can be trusted for, are, when of timber, made of one or more pieces according to the length required and the size and strength of timber that can be obtained; but in modern buildings they are very frequently made of wrought-iron, pieces of wrought-iron being sometimes bolted along each side, to afford facilities for fitting the bridging-joists, which are usually secured to the girders by tusk-tenons. By the aid of trussing, which, however, is of very doubtful value if the depth of the true beam is requisite, its power, to that of the beam, girders may be strengthened to any required degree, whether they be made of wood or iron. The principles upon which this effect is explained are applied under the names of 'Blackwood, P. C. S., vol. ii. pp. 218, 219, 231, 319, where is also a notice of Mr. Smart's suggestions for the further introduction of wrought-iron into floors and roofs.

The size or scantling of the various timbers in a double framed floor must of course be in accordance with the circumstances, being governed 'Architectural Dictionary,' art. 'Carcase Flooring,' says that binding-joists may be about ten inches by four, bridging-joists five inches by two and a half, and ceiling-joists about three inches by two inches and a half; the intervals being from four to six feet between the binders and eleven or twelve inches between the bridging and ceiling-joists. In the article 'Naked Flooring' in the same work he gives a minute account and illustrations of plans for constructing floors to the air for at least twelve months before they are used, the reason for planning them before this exposure being that the operation of planing opens the pores and causes the sap to flow. Many builders rear up their flooring-boards being placed alternately on each side of the rack, with their edges presented outwards, and a sufficient space between them to allow the air to circulate freely. The chief objection to this plan, as it is called, is that the ends of the boards become damp by resting on the ground; but this is
easily remedied by the simple plan of laying a horizontal pole along the foot of the rack to support the lower ends of the planks, and securing it a few inches above the ground, each plank being placed and the distance fixed very accurately both to support and comfort the shrinkage of the boards after they are laid should be reduced to the least possible amount. On this account, also, narrow boards are preferred, instead of seven or eight being laid in a row being extensively used. Sometimes much narrower pieces, formed by cutting planks into two or more widths, are employed, especially in superior houses, where a second planking of which, however, is laid over the principal floor and kind of veneering or finishing. An inch may be considered the least thickness which can be proper for flooring-boards, although, as shown by Batterie, P. C., p. 42, inferior rooms are frequently laid with boards of which three are cut from a batten originally under three inches thick. Ingenious machinery has been contrived and extensively used for the sawing and planing of flooring-boards; but such machines are frequently objected to as causing a considerable waste of timber, by cutting away much more, in width as well as in thickness, than it is needful to do in dressing them by hand. Hebert (Engineer's and Mechanic's Encyclopedia, art. "Flooring") describes a device for planing the tongueing of such a machine, invented by Mr. Muir, of Glasgow, and which has been brought into use in several extensive establishments, by which, while the simple planing of the surface may be performed, the tongueing is also done at the same time, and, if required, to cut grooves in them for the purpose of tonguing the joints.

The most common mode of laying floors is by the operation termed "folding," the floors thus laid being termed "folded floors." In this operation one board is first laid down and secured firmly by nailing to the joists. Another is then laid down and fastened in like manner precisely parallel with it, but at such a distance from it as barely to leave room for a second, three, four, or any other determinate number of intervening boards. When, therefore, these intervening boards are laid in the place provided for them, being rather too wide for the space, they buckle up in the form of an arch. Boards are then laid across them, and upon these boards two or three men jump until the flooring-boards are forced down flat to the joists, to which they are securely nailed. Another portion of the floor is then laid in the same manner. The edges of the boards in a folded floor must of necessity be plan or square, and the boards must be nailed to the joists near both edges, in consequence of which it frequently happens that in shrinking they split or crack along the middle. In superior floors joints formed by ploughing and tonguing, or by rebating and lapping the adjoining edges, are often used. Boards may be purchased with the tongueing already made, that is, allowing for the movement consequent upon shrinking, without impairing the air-tight character of the floor, which is not only important for comfort, but also as a check to the progress of fire. The best floors are dovetailed, and nailed at one edge only, the nails being driven in obliquely through the edge, so as not to show at all on the surface. Some workmen insert the dovetail over the joints only, and others only over the interjoints, but perhaps the best way is to put them sufficiently close to have one over every joint, and one over every interval or interjoint. The gauge for the dovetails should be run from the under surface of the board, which should be straightened for the purpose. Flooring-boards, when worked by hand, are generally left rough on the under surface, excepting for a short distance from each edge, the intervening portion being merely smoothed with an adze at the points where the board crosses the joists. The floor may be laid flat, or it may be laid level by laying a number of thin boards of superior quality, which, if it be desired in order to produce any ornamental pattern, may cross the joints of the under flooring in any direction.

The practice of laying wooden floors above a vaulting of brickwork is alluded to under Fire-Proof Buildings. This is accomplished in various ways, the joints frequently resting upon wooden sleepers laid along the crown of the arches and the upper ribs of the iron girder from which they spring; dwarf walls or piers being raised where it is necessary to provide a level support for the sleepers. Though the spandrels may be filled up with brickwork or concrete, a space for the free passage of air should always be left between the brickwork and the timbers of the floor. Stone floors or pavements are also noticed in the article above referred to. Under ordinary circumstances they are laid upon brick arches, but they are occasionally used upon panes of plate glass or metal, upon which the timbers are occasionally used in public buildings, and have been very highly recommended for the floors of warehouses. The extraordinary strength and durability of this material, which may be obtained in thin sheets, renders it peculiarly fit for such an application; and the facility with which, owing to its non-absorbent character, it may be cleaned with washing, has been found a great recommendation in some of the large departmental shops. In some other respects, and other things are liable to be split. Floors of sheet-iron have been constructed in some fire-proof buildings, the Pantechnicon, for example; but they are inconvenient from their extreme width, and are not sufficiently firm against the boards, and makes the joint exceedingly close. In using either this cramp, or the cheaper substitute for it called a dog, it is well, to lay a loose fillet between the cramp and the edge of the board, to preserve it from injury by the force exerted. Any floor thus laid a place to lay it up with brickwork to be straight-jointed, as distinguished from a folded floor.

The heading-joints, or those between the ends of the flooring-boards, have been variously formed and applied, as being air-tight, which it can only be by virtue of excellent workmanship and some peculiarity of construction, is a very important preservative against the spread of fire, and is also useful by enabling the builder to introduce a current of air among the timbers by means of iron air-hricks, without occasioning any unpleasant draught in the rooms. It is always highly important, for the preservation of the timber, to do this in the case of floors laid in a basement story, which rest upon what are termed ground-joints laid upon brick or stone piers or dwarf walls; and in many of the best London houses it is also done for upper floors, the air-hricks being sometimes concealed by architraves, sometimes being made to appear as a sort of cornice, the air thus admitted is sometimes allowed to enter the chimneys through the jambs for the sake of producing a good draught, while the connection with the atmosphere allows the means of more easy and rapid ventilation of the smoke. In laying these in the ornaments of the ceiling. A method of laying floors which is adopted in some buildings of a superior character, and which is very effectual both in rendering the floor air-tight and in checking the transmission of sound through it, consists in laying a kind of secondary floor of short rough pieces of wood upon fillets nailed to the sides of the joists, about midway between their top and bottom edges, and covering the whole surface of the secondary floor, which is allowed to dry before the flooring-boards are laid, and upon which is sometimes laid a stratum of broken slabs. This secondary floor, or sound-boariding, consists of thick laths, or slips of wood not exceeding an inch or an inch and a half in width, with the joints a little open, that the pugging may key to it like plaster to the laths of a ceiling. In the first-rate houses in which this plan is adopted, the floor is first laid with very narrow boards, often not exceeding two or three inches, between which, at intervals of a few feet, a small opening is left to allow the perfect evaporation of moisture from the pugging. This first floor of narrow boards, which, from their thin width, are incapable of warping to any serious extent, is the only one laid until the completion of the painting, and all that is likely to occasion injury to the boards, are the coatings itself, to which they are left on the floor of thin boards of superior quality, which, if it be desired in order to produce any ornamental pattern, may cross the joints of the under flooring in any direction.
How

In out-buildings, floors or pavements of bricks and tiles are used. In the town of 'Petersham,' 1640, however, they may and may be laid either in dry sand, in mortar, or in cement. The better kinds of brick pavement are laid with a peculiar kind of hard brick made for the purpose, and sometimes used also in the making of walls. But bricks are also laid in having both of the different kinds of pavements. Flat brick pavement is very fragile, and is damp from the earth upon which it is laid; but brick-on-edge pavement is in some cases superior to stone, supposing the stone to be laid immediately upon the ground. When used for loosercells, patries, dairies, or staple, brick-on-edge pavement laid in dry sand is convenient from the facility which it affords for the escape of fluids split upon it. Some paving bricks are so divided that one brick is having both sides flat, and being only two inches or two inches and a half thick. A small hard kind, called Dutch chinks, is used almost exclusively for brick-on-edge herring-bone pavements, in which the bricks of each course inclined, at an angle of 45° to the direction of the course; and each course is inclined in the opposite direction to the adjoining one. Square paving tiles, laid in courses like stone pavements, make a very neat and beautiful roadway for Park and Pleasure grounds.

[Blank page]
Proclaimed in 1813, and especially advised him to keep the solemn promise he had given to introduce a general national representation. Unable to oppose a barrier to the king's policy, Humboldt, Beyme, and Boyen tendered their resignation, and Humboldt again retired to Tegel, where he henceforth devoted all his leisure to philosophy, until the death of April, 1832. During forty years he had enjoyed the well-deserved reputation of one of the greatest philosophers and linguists of the age, and the proofs that the rule of the human.

The number of languages, most of them barbarous or half civilized, which he had thoroughly studied, besides the classical languages, was very great. He acquired the most perfect knowledge of the Hebrew, the Arabic, the Persian, and Sanskrit, in a shorter period of years than others would have spent years in learning them. He was equally distinguished for the views he took in comparing the development of languages with the development of the human mind, as well as in comparative grammar; and as a critique of the ideal in poetry, philosophy, and the fine arts, he had few equals in Germany. Humboldt was mediocre as a poet, and it seems he felt his inferiority in this respect, for after having published a few poems, he stopped. He left a great number of poems in MS., chiefly sonnets, most of which were afterwards published by his brother Alexander; but though they are beautifully written and of a most elegant and dignified style, they are not equal to the mental Schiller, in a letter which was written when Humboldt first attempted authorship, speaks thus to his friend:—

"I am convinced that the principal cause which seems to prevent you from publishing is the complete absence of reasoning faculties of your mind over the creating faculties, and consequently the preventive influence of criticism over invention, which always provokes destructive to mental production. But I will not consent to the opinion that only through abstractions in science nothing can be created but by "subjective" activity. In many concerns I cannot call you a genius; yet I must avow that you are a genius in others. For your mind is so powerful a vehicle of genius that at certain times exactly the contrary of all those who are merely conspicuous through their reasoning faculties, through learning, through improvement, through criticism, and which will not stop at the perfection within the sphere of mental creation, but within the sphere of reasoning."

Schiller's judgment was at once frank and correct: the spirit of universal criticism was emboldened in Humboldt, who, with the exception of one large work which he left unfinished in MS., composed only minor works, most of them critical essays, which he published at different periods. The greater part of them was collected by his brother Alexander, and published with the title of Vaskischen Werke, Berlin, 1841, 4to. vol. 8vo.

The principal productions contained in the first volume are—Two Memos about the Iberian Provinces; a Supplement to the Memoirs of the Royal Academy of Berlin, and in Schlegel's 'Jahrbücher'; A Critique on F. A. Wolf's second edition of Homer's Iliad and Odyssey; a sketch of a Grammar and System of the Basque Language; 'Communicating of royal fulness for the publication in the home ministry, but tendered his resignation two years afterwards, and for some time retired to his seat at Tegel, near Berlin, where he devoted his time exclusively to literature, till, in 1813, he was sent as ambassador to Vienna. In this capacity he took part at the Conferences of Prague in the summer of 1813, where, after long negotiations, Austria gave up her neutral position and espoused the cause of Prussia and Russia. During the campaigns of 1813 and 1814 he was in the headquarters of the King of Prussia, Frederic William III. at the conferences of Châtillon; signed with Hardenberg the Treaty of Paris; and after the peace declared the embassy at the courts of minister-plenipotentiary of Prussia, together with Hardenberg, at the Congress of Vienna. The treaty of 1815, through which the King of Saxony lost one-half of his kingdom, which was given to Prussia, was contrived and signed by Humboldt. He continued his diplomatic career at Frankfurt, where he made himself conspicuous through his conciliatory eloquence in the delicate business of dividing Germany among its princes, and afterwards as ambassador at the court of St. James's, which he left during a short time in order to assist at the Congress of Aix-la-Chapelle. In 1819 he was appointed minister plenipotentiary at the Congress of Verona, to represent the policy of the King of Prussia was supported by the states-chancellor, Prince Hardenberg; but Humboldt and the ministers von Beyme and von Boyen tried to persuade the king to be faithful to those liberal principles which he had acquired on a State Plenipotentiary, by the treaty of Vienna, and being the model assisted himself, James's policy, Humboldt, Beyme, and Boyen tendered their resignation, and Humboldt again retired to Tegel, where he henceforth devoted all his leisure to philosophy, until the death of April, 1832. During forty years he had enjoyed the well-deserved reputation of one of the greatest philosophers and linguists of the age, and the proofs that the rule of the human mind.

The number of languages, most of them barbarous or half civilized, which he had thoroughly studied, besides the classical languages, was very great. He acquired the most perfect knowledge of the Hebrew, the Arabic, the Persian, and Sanskrit, in a shorter period of years than others would have spent years in learning them. He continued his diplomatic career at Frankfurt, where he made himself conspicuous through his conciliatory eloquence in the delicate business of dividing Germany among its princes, and afterwards as ambassador at the court of St. James's, which he left during a short time in order to assist at the Congress of Aix-la-Chapelle. In 1819 he was appointed minister plenipotentiary at the Congress of Verona, to represent the policy of the King of Prussia was supported by the states-chancellor, Prince Hardenberg; but Humboldt and the ministers von Beyme and von Boyen tried to persuade the king to be faithful to those liberal principles which he had
Cesar, Strabo, and other ancient writers. In the countries immediately east of the Rhine, particularly in Austria and the Tamaric (Galicia), the ancient names are exclusively Celtic that the author concludes that both those nations were pure Celts. The Iberians, according to Humboldt, were not the African Berbers, but the ancient inhabitants of Spain, probably the same. The second volume also contains a Memoir on the Limits within which Governments ought to confine themselves in their care for the welfare of their Subjects; A metrical German translation of the 1st, 12th, and 14th of Pindar's Olympic Odes; the 1st, 2nd, and 4th-9th of the Pthian Odes, among which No. 4 appeared first, with a commentary, in the 'Neue Deutsche Monatsberichte' (1811), and No. 41 of Trachtenberg's 'Ueber Hornen' (1797); the 4th, 6th, and 10th of the Nemean Odes; Forty-one Sonnets printed from MS., &c. The contents of the third volume are:—A metrical German translation of the Arachnomachia, first published, Leipzig, 1816, 4to., considered to be a masterpiece; a metrical German translation of the Choruses of the Iphigenia; An Essay on the Drama in France, first printed in Goethe's 'Propylaeen'; A most interesting Memoir on Comparative Linguistic, treated historically, and first printed in the Memoirs of the Royal Academy of Berlin; Forty-two Sonnets from MS., &c. The fourth volume contains:—the celebrated critical essay on Goethe's 'Hermann and Dorothea' (368 pages), which the author first published in the first volume of his 'Aesthetische Versuche,' Bruns- wick, 1814; an account of different Sexes on Organic Nature; Fifty-seven Sonnets from MS. Humboldt's Essay on the Dual (Ueber den Dualismus), Berlin, 1828, 4to., is not in this collection. During the last ten years of his life he was actively engaged in investigating the Malay and American languages; but finding the task above his strength, he abandoned the American languages to his friend Dr. Boaschmann, for whom he afterwards obtained the place of chief librarian of the Royal Library at Berlin, and he devoted his time exclusively to the Malay languages, on which he intended to write an extensive work. When he died, the first volume was nearly finished, and the last eleven leaflets were delivered by Dr. Buschmann, to Alexander von Humboldt, who published it, with a preface of his own, under the title, 'Ueber die Kawi Sprache auf der Insel Java,' Berlin, 1836, 6vo., which attracted the attention of all Europe. The greater portion of this work comprehends investigations of the progress of civilization from the continent of India towards the large islands in the Indian Sea, which he teaches in the courses, the languages, and the literature of the different Malay nations; and only a small portion is devoted to the examination of the Kawi language. The death of the author is the cause of this impeded publication. If the MS. is in the hands of a scholar, which is very likely, it will be thoroughly treated in a second volume, the materials of which he collected, but left in such a state as to require the labour of a perfect scholar before they can be published. In the present volume, Dr. Humboldt has collected valuable materials, as well as a collection of rare MSS. and books, chiefly on linguistics, to the Royal Library at Berlin.

(Neuer Nekrolog der Deutschen; Allgemeine Deutsche Rev. 1817.)

HUME, James Deacon, born 28th of April, 1774, at Newcastle in the county of Surrey, was the son of Mr. James Hume, sometime secretary and afterwards a commissary of the customs, and who was nephew of Dr. Hume, bishop of Salisbury. The subject of this notice was sent when very young to Westminster School, and in that establishment received during the head masterships of Dr. Smith and Dr. Vincent, a liberal education.

In 1790, when at the age of sixteen, Mr. Hume was appointed to a clerkship in the Custom House, where he soon became conspicuous for that energy of character which accompanied him through life, so that at an unusually early age he was appointed to fill an office of much responsibility in the department. It was a maxim with him, which he frequently expressed, that a man should never content himself with performing merely his own duties, but all his powers should be exerted in the public service as far as his abilities would allow. He showed alacrity in assisting every one requiring assistance, and in extending to the utmost his ability the field of his usefulness. At the important event of the great fire that occurred on the 29th of June, 1790, Mr. Hume undoubtedly secured his own advancement in life, and attained to his deserved high reputation.

In 1798 Mr. Hume married. He had twelve children, eight of whom (daughters) lived to be women, and seven, with his widow, survived him. Shortly after his marriage he fixed his residence in part of a house in York Street, for which he rented a considerable extent of land, and commenced practical farming upon a large scale, not however neglecting his official duties, but giving daily attendance at his office, for which he allowed his landlord, at a small addition, to pay him for the privilege of entering the premises before daylight, returning to it after dark. He was always deeply interested in the science of agriculture in all its branches, and frequently in after-life referred to his practical experience as a farmer in support of those doctrines of political economy, of which he became a zealous and enlightened advocate.

In 1822 he was induced to relinquish his rural pursuits and again to take up his residence in London. By this time, his health had come to be highly important, and he obtained, by means of reports which it became his duty to prepare upon subjects connected with the revenue; and in the following year he was appointed to reduce into one simple code the many hundreds statutes (upwards of 1500), often contradictory of each other, and not unfrequently unintelligible, which at that time formed 'the intricate and labyrinthine chaos' of our custom-house legislation. This work had become one of necessity for it was as well a commercial as a commercial work. No other man could its performances have been intrusted with anything like the same propriety.

Three of the most valuable years of his life were devoted to the task, and to the unremitting labour which he applied to its accomplishment, his friends attributed that inward upon his bodily powers which was visible in the latter years of his life, and which heretofore could have been sooner than with his originally excellent constitution was to be expected. The labour of the task was intense. During its progress he allowed himself no relaxation, and of his studies spent working through the hours of the night and far into the morning. Of the value of the work thus performed it is hardly possible for any one to form an adequate estimate who should not have been practically acquainted with the condition of disorder that previously accompanied an important branch of the public business, and into which the acts prepared by Mr. Hume introduced clearness, harmony, and regularity. In the accounts of the customs, which he afterwards wrote, he has expressed his keenest admiration for the efforts of the late Dr. Hume's direction, and passed in 1826, everything was preserved that it was desirable to retain, while all that had become worthless in the many hundreds of repealed statutes was discarded. So intimate and confused had the laws indeed been rendered by successive patch-work pieces of legislation, that even those persons who had made it the study of their lives were often at fault in application, and the practice of our tribunals upon this branch was frequently contradictory.

So sensible were the ministers by whom this work was intrusted to Mr. Hume of the ability with which it was performed, that he was permitted by the department to retire in connexion with the sum of 4000L. over and above the salary of his office, from the duties of which he had been relieved during the period devoted to the task; and thereby cleared of every question of importance the present condition of the department at the country without his opinion concerning it having first been obtained. So frequent did these consultations become, that a room was fitted up for his use in the office of the Board of Trade; and at length, in July 1829, his services were wholly transferred to that department, where an office was created for him as Joint-Assistant Secretary. In the performance of the important duties thus intrusted to him, Mr. Hume used the same degree of zeal and intelligence which he had marked his previous course, and which secured for him the respect and confidence of the successive chiefs of the department.

At the beginning of 1840 the inroads upon his health caused by a long life of unremitting labour, were so apparent, that Mr. Hume's retirement from the public service became in a manner necessary. By this time he had completed forty-nine years of active service, forty-four of those years having been passed in situations of responsibility, and he was allowed to retire on a pension of the same amount as the salary attached to his office, which appears by a treaty by Great Britain to Parliament, he was expressed his lordship's full approval of his long and faithful services, accompanied by their regret that the public service would be deprived of his retiremént. He had been deprived of his duties by circumstances connected with the mercantile system of this country.' The regret thus expressed was in effect uncalled for, as on all occasions, up to the close of his life, on which his advice and experience were desirable, they were freely sought and con-
umbated; and it is probable that at no time during his active career was he able to render more essential service to the best interests of commerce, than by the suggestions made by him after his nominal retirement, and especially by the evidence given by him before the Import Duties Committee of 1849, evidence which, having been frequently quoted with commendation by all parties in the House of Commons, has been brought forward to support measures of reform in our fiscal system proposed and carried in conformity with his recommendations.

After an illness of some weeks' duration, but from which no serious result was apprehended, Mr. Hume was seized with a stupor of an apoplectic character, and two days thereafter died, on the 18th of January, 1849, in the sixty-eighth year of his age.

Although Mr. Hume may be almost said to have lived with the pen in his hand, he published but little, the object of his labours being for the most part confined to the preparation of official papers, which may, nevertheless, have exercised a greater influence upon society than could have followed from the publication of his essays.

His earliest papers upon subjects connected with commerce, which appeared from time to time in the British and Foreign Review, are of these, and upon the subject of mercantile law, in which he afterwards expended his labours as the author of a series of letters which, under the signature H. B. T., appeared first in the "Morning Chronicle" and have since been collected, and more than once reprinted. These letters contain many small compass, the most admirable and unanswerable arguments for various changes in our fiscal system, many of which have since been carried out, while others are evidently on the eve of adoption. Mr. Hume's style partook of the characteristics of his mind, which was vigorous and original.

In the private relations of life, Mr. Hume was remarkable for the most perfect sweetness of temper. With fewer of human weaknesses than are usually found to accompany even the more correct among us, he was ever indulgent to the failings of others; just in his dealings; true to his promises; with a largeness of generosity that, as such things are usually considered in this world, was ever attended by the most scrupulous delicacy towards those who were its objects. His attachments were strong and stable, and he was the object of the most earnest affections to all who enjoyed the privileges of his close acquaintance.

**HUMIDITY** is that property of a substance by which it communicates to a body in contact with it some of a liquid which it may have absorbed; and the term is commonly applied to the atmosphere when it is in a state to deposit moisture upon bodies in it.

The humidity of the atmosphere is caused in a great measure by the evaporation of water from the seas, lakes, &c. of the earth, and the quantity of moisture in the air is capable of containing depends upon the temperature; when the latter is low at any part of the earth's surface, the air may be saturated with moisture so as to be incapable of holding any more. Mr. Hume has shown that the quantity of moisture in a given volume of air will then be small. If the temperature be increased, the atmosphere, becoming thereby comparatively dry, acquires immediately the power of receiving more vapour, and the power increases with the temperature, so that, in a given volume of air, the quantity which consists with the state of saturation is also increased. Whatever be the quantity of vapour which constitutes the state of saturation, if the temperature be suddenly lowered, or if there be presented a body which has an affinity for water, a precipitation of the latter takes place, or water becomes absorbed in the body.

Due, P. G.; Rarx, P. C.

The temperature of the atmosphere over any place on the surface of the earth diminishes as the distance of the stratum of air from the surface increases: the power of the air to hold vapour in any given volume is thereby reduced; and, as a general law, it may be stated that the humidity of the atmosphere decreases from the surface of the earth upwards. The great dryness of the atmosphere near the summits of mountains has been frequently remarked by travellers, but the quantity of moisture in the different strata is, from local influences, subject to many irregularities. The temperature of the lower strata of the atmosphere diminishing as the altitudes of places on the earth decrease in volume of air, and if the atmosphere be completely saturated, will contain less water as a station is farther from the equator; and the like may be said of the entire column of the atmosphere over a station. This may serve to account for the fact, that, in general, the weather becomes fresher with increase of altitude, and, in the tube of air through which the air is slowly ascended, by the increased density of the air, the clouds are made to ascend in the atmosphere to a region where, the dryness being great, they are readily dissipated. On the contrary, when the mean density of the atmosphere diminishes in length, the clouds descend; and arriving near the earth, they enter a region in which the atmosphere is at or near the state of saturation; when, consequently, the vapours are easily precipitated. Biot observes, on this subject, that the descent of the mercury is a more certain prognostication of rain than its ascent is of fair weather; the ascent of the clouds in consequence of an increased density of the air not being necessarily accompanied by the dispersion of the vapours produced by high winds, the upper regions of the atmosphere are often charged with aqueous vapour; and rain may then fall while the top of the column of mercury is above its mean height, and even while it is rising in the tube.

The atmosphere often becomes humid from the evaporation of liquids by artificial means. In establishments for brewing, dyeing, and the like processes, the air is filled with liquids which are constantly in a state of ebullition rise in the atmosphere, and even render it opaque. The breathing of men and animals produces a watery vapour which renders the atmosphere humid, and the eye of the experimenter, if assembled in a close apartment the humidity is sometimes so great that water flows down the walls. The leaves of plants also discharge, in the form of vapour, the water which is absorbed in their leaves; and in conservatories this effect is particularly sensible.

In order to determine the quantity of water which is contained in earth when completely saturated with rain, Dr. Dalton calculated the quantity of garden mists, which fell copiously during the preceding day, and exposed it to different degrees of heat. When it seemed to have about the same degree of moisture as soil at the depth of two inches from the surface in summer weather, he weighed it, and found that it had lost one-twelfth of its weight; and when it had lost two-ninths of its weight it seemed like the upper soil in summer. His conclusion is that a body of earth one foot in depth, and one foot in width, when saturated with water, contains, on an average, as much as a foot of water, which is about one inch in depth of water, and that it may lose one-fourth or one-half of that quantity without becoming incapable of supporting vegetation.

The effects of humidity on the dimensions of bodies are various: when a wet body penetrates between the twisted fibres of cordage, which are vegetable materials, the cordage swells out transversely, and thus becomes shortened; while cords made of animal substances become relaxed by humidity and increase in length. Most salts absorb water, and thereby increase in weight.

**HUMIRIACEAE** is a natural order of plants belonging to the family Humiriaceae of Polypetalous Euphorbeae. It has the following essential character:—the calyx is in 5 divisions; the petals alternate with the lobes of the calyx and equal to them; the stamens hypogynous, 4 or many times as numerous as the stamens, free; the anthers discoid, longitudinally connate, extended beyond the 2 lobes; the ovary superior, usually surrounded by an auricular or toothed disk, 5-celled, from 1 to 2 suspended ovules in each cell; the style simple, the stigma lobed; the fruit drupaceous, with 5 or fewer cells; the seed with a membraneous integumen, the embryo straight, oblong, lying in flabby albumen; the radicle superior. The plants belonging to the order are trees or shrubs abounding in a resinous juice, with alternate, simple, coriaceous exstipulate leaves, and axillary coryls of flowers.

The affinities of this order are not well made out. In their albinomous sea-quantities of skidder embolus they agree with Subulaceae, as also in their balsamic wood. They resemble Malacca and much in habitat and in their fructification, but the authors and seeds of Humiriaeae differ very much from those of Meliaceae. Agreeing in the general law, it may be stated that the humidity of the atmosphere decreases from the surface of the earth upwards. The great dryness of the atmosphere near the summits of mountains has been frequently remarked by travellers, but the quantity of moisture in the different strata is, from local influences, subject to many irregularities.

The temperature of the lower strata of the atmosphere diminishing as the altitudes of places on the earth decrease in volume of air, and if the atmosphere be completely saturated, will contain less water as a station is farther from the equator; and the like may be said of the entire column of the atmosphere over a station. This may serve to account for the fact, that, in general, the weather becomes fresher with increase of altitude, and, in the tube of air through which the air is slowly ascended, by the increased density of the air, the clouds are made to ascend in the atmosphere to a region where, the dryness being great, they are readily dissipated.
foet in height, with ovate oblong leaves half-clasping the stem, which becomes in maturity narrower and longer than the leaves, the peduncles smooth as well as the petals. This tree is a native of Guyana and Cayenne. Its bark is thick, and abounds with a red balsamic fluid, which results from the wound. A house in which this tree is thus wounded becomes hard and transparent, and when burnt affords an agreeable odour. The negroes and natives of Guyana use the bark in slips for the purpose of flameaux; they also use the wood for building their houses. We have no account of its composition of this resinous juice, but Ashtel suggests that it might be used as a substitute for the Peruvian balsam. The Creoles call this tree "Red-wood," on account of the colour of the wood and also because of the mainly of Hellicera and Sncoclytis, yield resinous juices.

Lindley, Natural System; Burnett, Outlines of Botony; Don, Gardner’s Dictionary.)

Hungary. Among the kings of Hungary there are three of the name of Andrew, or Andrews, who deserve a short notice.

Andrew I., the son of Prince Ladislaus the Bald, and the fourth king of the house of Arpad, reigned from 1046 till 1061. His predecessor, King Peter, in 1045, had offered Hungary as a fief to the Emperor Henry III. of Germany; but Andrew refused to take the oath of vassalage, and after a prolonged war he proclaimed himself king, 1052, through which all feudal ties between Hungary and the empire were abolished. During the reign of this king the movements of the Hungarians and the Bulgarians were succeeded in introducing the Christian religion throughout his kingdom. Andrew fell in battle with his brother Bela, who succeeded him on the throne.

Andrew II., Hierosolymitanus, was the son of King Bela III.: he succeeded his elder brother Emmeric in 1205, and reigned till 1235. During his long reign Hungary was shaken by disturbances and civil and foreign wars, caused by the reckless and ambitious character of Andrew, whose passions however were more violent than strong. Previous to his accession he waged war with his own brother Emmeric, and raised a numerous army. They were encamped in sight of the city, and were long kept in suspense. At last it is reported that the partisans of Andrew followed him only through fear, went alone and unarmed, with only a white staff as the symbol of peace in his hand, to the camp of the rebels. When he was in sight of them, "I shall see," said he, with quiet dignity, "whether you will shed royal blood." None of them dared to stop him, and he thus surprised his brother Andrew in his own tent, and after having reproached him for his conduct, prevailed upon him to submit without making even an appeal to his followers. In this way Emmeric carried Andrew from the midst of his own army, and kept him in prison till 1210. This event only ended the troubles of Hungary. Andrew was brought before him, and appointed him guardian of his son Ladislaus, who was a minor. After Emmeric’s death, Andrew seized the royal authority and reigned in his own name till 1235, and then died, in 1235, in Hungary, so that Andrew became legally possessed of the supreme power which he had usurped. Andrew was a slave to his beautiful but haughty queen Gertrud, a princess of Memnon, whose conduct became so unseemly that the principal Hungarian nobles conspired against her life, and during the absence of Andrew in Galicia, in 1213, they surprised her and put her to death. The conspirators were headed by the Magnate Buncu, whom the queen had mortally offended; for in order to take revenge for a slight offence which she pretended to have received from Buncu’s wife, who was famed for her beauty and virtue, she prevailed upon her brother Berthold to violate the person of this lady, and she afforded him an opportunity of effecting his purpose in the queen’s own apartments in the royal palace. In 1217 Andrew undertook a crusade, and made himself conspicuous in Palestine through his gallant deeds, but his final success was trivial, and he returned in 1222: thence he was called 'Hierosolymitanus.' Andrew took an important part in the Byzantine state. He married Theodora Constantincou, Peter of Courtenay, in 1217, the crown of Greece was offered to Andrew, who however declined it, and, in 1218, made a treaty of alliance with Theodore Lascaris, the ruler of Cyprus. In 1222, he married his second son in marriage to Andrew’s eldest son Bela. When Andrew returned from Palestine, he found this prince at the head of an army of rebels, and his kingdom disturbed by a civil war. The power of the nobles was so great that in the diet in 1229, which Andrew convoked immediately after his return, they forced him to subscribe the "Aurea Bulla," or "Golden Bull," which has justly been compared with the English Magna Charta, and by which great privileges were given to the Hungarian nobles, while the royal authority was still considerably diminished. This was a mark of the political law of the kingdom of Hungary and its appurtenances. During the following years Hungary continued to be shaken by civil factions, which the king was unable to quiet, since his natural abilities and his good will were not supported by sufficient steadiness of character. Andrew II. died in 1236, and was succeeded by his eldest son Bela IV.

Andrew III., the son of Prince Stephanus, who was the posthumous son of Andrew II., was crowned King Charles Ladislaus IV. in 1290. His short reign of ten years was signalized by civil disturbances and foreign wars. Andrew compelled Duke Albert of Austria to give up his claims upon Hungary, with which he had previously been invested by his father the Emperor Rudolph I. of Germany; whereupon the two princes joined against Charles Martel, Prince of Naples, who founded his claim to the Hungarian crown upon his descent from Maria the sister of the last king of Byzantium. Charles Martel having died before he was able to prepare an expedition against Hungary, his case was taken up by his son Charles Robert, who, having found support among a powerful faction of the emperor, made his claim to the Hungarian crown. He entered that country in 1300, and took the field against Andrew. The failure of the royal arms against the invaders of Hungary, was accompanied upon the 20th of May, 1301, the death of Andrew. Thus, in the same year. Andrew III. was the last king of the house of Arpad, the founder of the Hungarian kingdom; and his successor, the fortunate Charles Robert, was the first king of the house of Anjou or of the Savoy, that reigned over Hungary during nearly a century.

(Mailath, Count of, Geschichte der Magyaren; Pray, Historia Regnum Hungaria.)

HUNTINGTON, ROBERT, D.D., was born in February, 1836, at Deobryt, in Gloucestershire, where his father, of the same name, was parish clergyman. After having received the rudiments of a classical education at the free school of Bristol in 1842, he entered Merton College, Oxford; and, having taken his bachelor’s degree in 1858, he was soon after elected to a fellowship in that college. He took his degree of Master of Arts in 1863; and, having then applied himself with great success to the study of the Oriental languages, he was in 1870 appointed to the situation of chaplain to the English factory at Aleppo. This post he held for above eleven years, during which time he visited Jerusalem, Galilee, Samaria, Cyprus in 1877, and Egypt in 1880, and again in 1881, besides making an unsuccessful attempt in 1878 to reach Palmyra. He returned home in 1884, and continued his studies in the same way, so that he accumulated the degrees of bachelor and doctor in divinity in June of the following year. In the latter part of that year he was prevailed upon with much reluctance to accept the pension of £400 a year; and he was presented by Sir Edward Turner to the rectory of Great Hallingbury in Essex; and while he there married a sister of Sir John Powell, one of the justices of the King’s Bench. He seems still, however, to have feltuntiring in what he describes in some of his printed letters as a rustic solitude, where he was banished alike from books and friends, from the living and the dead; and, although he had some years before refused the bishopric of Exeter in Ireland, his aversion to that country gave way so far that in 1701 he consented to accept of that of Raphoe. But he died there on the 2nd of September in the same year, twelve days after his consecration.

The only literary performance that Bishop Huntington published was a short paper in the ‘Philosophical Transactions’ (No. 161), entitled, ‘The Hieroglyphics of the Porphyry Pillars in Egypt.’ The writer of his Life in the ‘Biographia Britannica’ states that some of observations are printed in Ray’s ‘Collection of curious Travels and Voyages,’ 2 volumes, a work of which the first part was in marriage to Andrew’s eldest son Bela. When Andrew returned from Palestine, he found this prince at the head of an army of rebels, and his kingdom disturbed by a civil war. The power of the nobles was so great that in the diet in 1229, which Andrew convoked immediately after his return, they forced him to subscribe the ‘Aurea Bulla,’ or ‘Golden Bull,’ which has justly been compared with the English Magna Charta, and by which great privileges were given to the Hungarian nobles, while the royal authority was still considerably diminished. This was a mark of the political law of the kingdom of Hungary and its appurtenances. During the following years Hungary continued to be shaken by civil factions, which the king was unable to quiet, since his natural abilities and his good will were not supported by sufficient steadiness of character. Andrew II. died in 1236, and was succeeded by his eldest son Bela IV.

Andrew III., the son of Prince Stephanus, who was the posthumous son of Andrew II., was crowned King Charles Ladislaus IV. in 1290. His short reign of ten years was signalized by civil disturbances and foreign wars. Andrew compelled Duke Albert of Austria to give up his claims upon Hungary, with which he had previously been invested by his father the Emperor Rudolph I. of Germany; whereupon the two princes joined against Charles Martel, Prince of Naples, who founded his claim to the Hungarian crown upon his descent from Maria the sister of the last king of Byzantium. Charles Martel having died before he was able to prepare an expedition against Hungary, his case was taken up by his son Charles Robert, who, having found support among a powerful faction of the emperor, made his claim to the Hungarian crown. He entered that country in 1300, and took the field against Andrew. The failure of the royal arms against the invaders of Hungary, was accompanied upon the 20th of May, 1301, the death of Andrew. Thus, in the same year. Andrew III. was the last king of the house of Arpad, the founder of the Hungarian kingdom; and his successor, the fortunate Charles Robert, was the first king of the house of Anjou or of the Savoy, that reigned over Hungary during nearly a century.

(Mailath, Count of, Geschichte der Magyaren; Pray, Historia Regnum Hungaria.)
he had just heard from Aleppo that some English gentle-
men, out of curiosity going to visit the ruins of Palmyra, had found 400 marble columns, of a sort of porphyry, and also
observed some temples yet entire, with tombs, monuments,
Greek and Latin inscriptions, of all of which he hoped to
give a true account; and probably be able to profess to have
received by the English public the successful accomplish-
ment of the modern journey to Palmyra, which was
achieved by some gentlemen of the faculty of medicine
and of which a full account was given in the Philosophical
Transactions' for 1665. Bay's book may have been printed in
the latter part of 1692, though not published till May,
1693, for the first number of the journal for that month
is dated.

Dr. Huntington is principally remembered for the numer-
ous Oriental manuscripts which he procured while in the East
and brought with him to this country. Besides those which
he purchased for Archbishop Marsh and Bishop Fell, he ob-
tained between six and seven hundred for himself, which
are now in the Bodleian Library, to which he first presented
thirty-five of them, and then sold the rest in 1691 for the
small sum of 200£. Huntington, however, missed what was
the principal object of his search, the very important Syriac
version of the epistles of St. Ignatius, a large portion of which
was at length recovered in 1654 by Mr. Tatton from one of
the ruins near Palmyra which had been purchased in the
course of his inquiries, and, having been deposited by him
in the British Museum, has been published in the present
year under the care of the Reverend William Cureton, keeper
of the oriental manuscripts in that establishment. Huntington's
letters, which are addressed to the Archibishop of Mount Sinai,
contain inquiries about the MS. of St. Ignatius; and the same earnest
inquiries are made in his letters to the Professor of Hebrew.

There is a Life of Bishop Huntington, in Latin, by Dr.
Thomas Smith, at the end of which are thirty-nine of his
Letters, &c., published in 1801, at London, in 1704; and
he also subjoins an article in the 'Biographia Britannica.'

HURA, a genus of plants belonging to the natural order
Euphorbiaceae. It has noneesecious, ameneaceous flowers; the
stamens are shorter than the calyx; the truncaceous; the stem;
united into a solid column; the pistillaceous flowers with the
style simple, and the stigmas with 12-18 rays, and the capsule
with 12-18 cocci. H. crpephana is a tree abounding with
milky juice. It is a native of the West Indian Islands,
Mexico, and Guyana, where it is called ' Sandbox,' or ' Mon-
key's Dinner-Bell.' It has corolae, accuminate, entire or very
slightly toothed, stalked, smooth, coriaceous leaves, with simple
veins passing from the midrib to the margin in a curved
direction, within a quarter of an inch or so of each other,
and connected by numerous oblique veins; large, ovate,
leafy, deciduous stipules, and petioles as long or rather longer
than the blade. The fruit is a 2-gland a一天 that
tree is a depressed umbilicate woody capsule, about
the size of a muddling apple, from 12-16 furrows which
separate into as many cocci, each of these separates into
2-3 segments with gouty teeth when dry and fully ripe. The noise the fruit makes during this process
has obtained for the tree its common names. The juice of the plant, like that of the allied genus Excerraria (Eccceraria,
P. C. S.), is exceedingly acrid, and a small quantity touching
the eye will produce blindness. The seeds, like those of
Croton and Ricinus, contain an acrid oil which is a drastic
and dangerous poison.

(Lindley, Flora Medica; Burnett, Outlines of Botany.)

HURRAH, also called Hurrar and Adhuri, is a country
with a large commercial town in the eastern part of Africa,
and is situated midway between the Horn of Africa and Ankor, the cap-
ital of Saba [Amana-
cia, P. C. S.] and the harbour of Burmah. As the place
has not been visited by Europeans, its true situation is
not known, and our information about it is derived from the ac-
tounts of some natives of the adjacent countries.

According to these accounts, the town is so large that it
takes two hours to go round it at a quick pace. It is sur-
rrounded by a wall of stone and mud, which is about twelve
feet high and three feet thick, and kept in good repair.
There are five gates. The houses are generally built of stone
and whitewashed, with flat roofs. There are however some
few- or resembling those in Shoa. The emir and the prin-
cipal men have houses but two stories high. The houses are
said to be many mosques within the town, forty-four of
which are the abodes of learned men. The town is well sup-
plied with water from numerous springs in its vicinity. Close
to the town is a river called Samhi.

The inhabitants are rigid Mohammedans, and pay strict
attention to the fasts and ceremonies enjoined by that religion.

The inhabitants of Hurrar are said to be hospitable and
kind, and those who are of the genteel sort are not
averse to the use of tobacco and wine. They have some
unusual attire, consisting of a white or black veil, and a
robe resembling a nightgown, which they wear in the
daytime.

Hurrar may certainly be considered, for that country, a
great commercial town. Kaffars arrive there or depart at
all times and seasons. They have a yearly trade of 3000 bales of
cloth and Burbruz and Zeila, which two last-mentioned places
may be considered as the ports of Hurrar. Three kaffars
visit Burbruz between the months of October and March. The
exports consist of 2000 camels. They export coffee, jowari, guava, ostrich
feathers, gum, myrrh, and urr; the last-mentioned article is
said to denote appearance, and is used by the Arabs as oint-
ment for the body. It is also made up into cakes, which are said to be
very palatable.

They also export Burbruz slaves, both male and female,
and receive in return blue and white coarse cloth, Indian
piece goods, European prints, red cotton-
yarn, burlas, zinc, copper-wire, frankincense, and some
smaller articles. There are also annually three kaffars to Zeila. The
kaffars make a trade of importing from Zeila, chiefly blue cloth, red
cotton-yarn, &c., and receive in return slaves, mules, and
horses. Other kaffars trade between Hurrar and Arusich
and Chercher, two towns or encampments of the Galia, situated
west and south-west of Hurrar; the articles of export and
import are imperfectly known.

The climate of Hurrar is said to be similar to that of Shoa,
but not quite so cold. The language bears an affinity to the
languages of the North Arabian district, and the character
is used in writing. The ruler of Hurrar has the

of Hurrar, in London Geographical Journal, vol. viii.; Christo-

...}

HUSKISON, WILLIAM, was born March 11, 1770, at
Birch Moreton Court, Worcestershire, where his father
occupied an extensive farm. The family had long been
situated in that part of the county, and had been
in the possession of a moderate landed estate on which
they resided. On the death of his mother, in 1774, his father
removed into Staffordshire, married a second wife, and
resided upon his patrimony until his death in 1790. He had alien-
ated a considerable portion of his property in order to make
provision for his younger children. The entailed property
descended to the subject of the present notice, who cut off
the entail and disposed of the landed property altogether.

In 1788, when in his fourteenth year, William Huskisson
was sent to Paris, at the request of his maternal uncle, Dr.
Gren, physician to the English Embassy. Dr. Gren was on
the terms of friendship with D'Achabie, the celebrated
raconteur, who was afterwards known as the Encyclopædist. William Huskisson, as
natural to a young man, became an enthusiast in the cause of
the French Revolution. He was present at the taking of
the Bastille in 1789, and became a member of the Société

...
Huskisson, the duke laid it before the king. In the correspondence which ensued it is evident that the Duke of Wellington was not disposed to support Huskisson. He had once before voted against his ministerial colleagues, in opposing, in 1822, Lord Londonderry's resolutions for the protection of the agriculturists; but at the request of Lord Liverpool, the prime minister, he remained silent. The agitation of Mr. Huskisson was followed by that of Lord Palmerston, Mr. Grant, and several others who had belonged to the political system at what was called "Mr. Canning's party." In the session of 1829 he appeared on several occasions as a formidable opponent of some of the measures of the government, and, for his death so soon afterwards, there is every probability that he would have been re-elected. Panic, commercial principles were held by him in common with them, and in his general views he was approaching towards the Whig party. He had always been in favour of the Catholic claim, and in opposing the repeal of the Corporation and Test Acts, he did so on the ground of its being a partial measure, and likely to retard Catholic emancipation. He supported in May, 1829, Mr. Grant's bill for relieving the Jews of their disabilities. He was for having supported a measure of reform, and in the same session he had voted in favour of giving representatives to Manchester, Leeds, and Birmingham.

Huskisson seldom spoke except upon financial or commercial subjects. He was an active member of the Bullion Committee, and defended the principles in the Report of that committee in a pamphlet entitled 'The Question concerning the Management of the Bullion of the Realm Examined,' which was published in 1810. In the debates on the corn laws, in 1814, he supported the system of protecting agriculture by high duties, on the ground that commerce and manufactures were protected by them. The system was one of artificial restraints. He was at that time merely for free trade in the abstract. He alluded to the possibility of import corn becoming one-fifth, instead of thirty-fifth of our consumption, if proper means were not taken to encourage the home cultivation. He was averse to the country being dependent on foreigners, and thought such circumstances not to be the means the object of its. He proposed a sliding scale of duties, according to which the duty would be 25 s. 8 d. when the average price of wheat per quarter was 65 s.; and as the price rose the duty would fall, so that at 68 s. there would be no duty at all. Corn from the colonies he would have admitted at one-half the rates of British corn. The question was postponed to the following year, and he supported the corn-bill of 1815, and thought that less than 65 s. as a protecting price would not remunerate the farmer. In the session of 1822 he moved a series of resolutions on the state of agriculture, one of which proposed that a tax of 2s. 6d. per quarter, which wheat should again reach 70 s. the quarter, a fixed duty of 15 s. should be laid on the import of foreign wheat. The experience of the last twenty-five years does not prove the profundity of Mr. Huskisson's views on this subject. In 1827 however he acknowledged that the policy of the corn laws must be viewed in the light of the changes in the growth, and price of corn abroad as well as at home; and he abandoned the corn-bill which had been brought in by the government, after the Duke of Wellington had carried an amendment the effect of which would have been to prohibit the release of bonded wheat so long as the price should be less than 68 s. the quarter. In 1819 he was appointed a member of the Committee for the mines. It is understood that he was principally concerned in drawing up the long Report of the Committee of Agriculture which sat in 1821. It advocated a relaxation of the corn-laws, for which he was never forgiven by the landed interest. In 1822 Mr. Wallace and Mr. Robinson (now Earl of Ripon) had taken some preliminary steps for relaxing restrictions on commerce; and those efforts were carried on more actively and on a larger scale by Mr. Huskisson. In 1819 he carried through parliament an act for enabling the king in council to place the shipping of foreign states on the same footing with British shipping, provided that similar privileges were given to British shipping in the same state. He aban-

Hus,

Hus.
he was attacked very generally, both in and out of parliament, for his departure from the antient commercial policy of the country. His speeches in Parliament in defence of his measures are his best; and his expositions of the commercial code are still among the most interesting. H. Parnell (Lord Congleton) has denied that Mr. Huskisson established free trade, but he states that in his speeches in 1825 he certainly proclaimed, and proved the policy of this system. . . .

He did no more than maintain the balance between the free-traders and the protectionists in taking a duty of 50 per cent, as the standard of regulation; and hints, that had he ever thoroughly espoused the cause of free trade, he had shown that he had the political power to advance it. He had of making improvements in his plan of 1825. (Financial Reform, p. 78.) But even the reforms which he did effect excited great clamour against opposition; and the advantages of the changes he had effected were not recognised until some time afterwards. Mr. Huskisson was active in procuring the repeal of the combination laws; and he relaxed the restrictions on the exportation of machinery.

At the close of the session of 1830 Mr. Huskisson left London to be present at the opening of the Liverpool and Manchester Railway, on the 16th of September. When the train reached Parkside, near Newton, he got out of the carriage, with many others, and had just been speaking to the Duke of Wellington, when an alarm was raised on the approach of an engine on the other line. Mr. Huskisson attempted to regain his seat, but fell to the ground at the moment the engine passed and was dashed to death. He was interred in the house of the Rev. Mr. Blackburne, of Eccles, but the shock to the system was so great that, after enduring great agony with much fortitude and resignation, he died at nine o'clock in the morning. At the funeral Mr. Huskisson's reputation and influence of the mercantile classes of Liverpool remains interred in the new cemetery, where a handsome monument with a statue was erected to his memory by his constituents.

Mr. Huskisson was married in 1799 to the youngest daughter of Admiral Milbanke, but had no family. On retiring from office in 1787, he entered upon the receipt of one thousand pounds a year. At that period his power was increased to grant for public services. He was nominated for this pension by Lord Liverpool shortly before his political demise. He was for many years Agent for Hoyton, the salary of which was increased from 800l. to 1200l. a-year: he resigned this post when appointed to the Board of Trade in 1823. (Speeches of the Right Hon. W. Huskisson, with a Biographical Memoir, 3 vols. 8vo., London, 1831.)

HUTCHINSIA. [Thalaspidea, P. C.] HUTTON, WILLIAM, was born at Derby, of poor parents, in 1765. By fine integrity he raised himself to opulence and eminence. It has been said of him 'that in many particulars of energy, perseverance, and prudence he deserves to be called the English Franklin. This may be done by his father, for his work in the silk-mill at Derby, which occupation he quitted at seventeen, and was bound apprentice to an uncle at Nottingham, who was a stocking-maker. He ran away during his apprenticeship, and wandered as far as Birmingham, the town in which he subsequently acquired a fortune; but distress compelled him to return to his uncle. The poor remuneration which he obtained for his labours at the stocking-frame induced him to look anxiously towards some other means of gaining a livelihood; and in 1786 he bought an old worn-down press, and taught himself the art of bookbinding. In 1790 he walked to London and back to purchase a few books, at this time, of the year. He commenced attending the market-day, and here he rented a shop at twenty shillings a year, and opened it for the sale of books. In his biography he says: 'During this rainy winter I set out at five every Saturday morning, carrying a burthen of from three pounds' weight to thirty, opened shop at ten, starred in it all day upon bread, cheese, and half a pint of ale, took from one to six shillings, shut up at four, and by trudging through the solitary night and the deep roads five hours more, I arrived at Nottingham by nine, where I always found a mess of milk-porridge prepared by the bellman, and a loaf of bread, which my mother's sister was a woman of superior mind, and he owed much to her encouragement. His object was to save a small sum to enable him to commence business in a large town; and in 1790, after having twice visited Birmingham in order to see the chances of success which the place offered, he on one third visit took the lesser half of a small shop, at a rent of one shilling per week, and furnished it with a small supply of books. The overrears teased him for two years under the styles that he would not always pay in time, and at last, his shillings a week covered all his expenses, and at the end of the first year he had saved 30l. Fortune continued to smile upon him, and in 1796 he married. In 1791 his property was estimated at 200l. a-year, and he purchased a house at Birmingham in that year, but after great difficulty he succeeded in recovering 500l. from the county. He now relinquished business in favour of his son. He had filled successively all the offices of the local society, and he purchased the 'History of Birmingham,' and this was followed by other works in the following order: 'Journey to London,' 1784; 'The Court of Requests,' 1784; 'The Hundred Court,' 1788; 'History of Blackpool,' 1784; 'Battle of Bosworth Field,' 1789; 'History of Derby,' 1790; 'The Barbers, a Poem,' 1793; 'Edgar and Elfrida, a Poem,' 1793; 'The Roman Wall,' 1801; 'Remarks upon North Wales,' 1801; 'Tour to Scarborough,' 1803; 'Poesies, chiefly Tales,' 1804; 'Trip to Coatham,' 1808.

Mr. Hutton died September 20th, 1815, a few days before the completion of his ninety-second year. In 1810 his daughter published 'The Life and Letters of Hutton, Statemaker of Birmingham, and the History of His Family: Written by Himself.' This work is one of the most entertaining and instructive pieces of autobiography in the language. An edition of this work was published with English Miscellanies. This edition contains some interesting notes by Catherine Hutton, Mr. Hutton's daughter, who was then in her eighty-fifth year; and passages of a personal nature from the original being a fragment of a larger work in the form of a letter to a gentleman of the name of William.

HYBRID PLANTS. [Sexes of Plants, P. C.] HYDATICA, a genus of fossil plants (probably aquatic) from the coal formation. (Aris.)

HYDE, SIR NICHOLAS, was appointed chief justice of the King's Bench in 1626. He was the uncle and preceptor of the first Earl of Clarendon, whose mind he had great share in forming, by proposing daily to him legal questions for his amusement, and regretting his failure in not being able to make him a peer. The court refused to allow to the prisoners their habeas corpus, and inflicted fines upon them of considerable amount. This conduct (Sir Nicholas Hyde's curious apology for which was the cause of the Roman Catholicogh, a bill to which he was not a party) was now voted by the long parliament a delay of justice. He died at his seat (Hinton Lodge), in the parish of Catherington, Hampshire, on the 28th August, 1681, aged 69.

Whitelocke, his colleague on the bench, and political opponent, records that 'the cause of his death was a hot fever, rendered incurable by reason of an imposthume breaking in his head; and that he lived in his place of chief justice with great integrity and uprightness, and with great wisdom of temper, considering the ticklishness of the times.' (Rushworth, vol. ii. p. 111.) Four of his letters are extant in the Bodleian Library. A very beautiful full-length marble effigy of him still exists in the church of St. Katharine, Hants.

He was succeeded in his estate by his son, LAWRENCE HYDE, who became principally remarkable for the personal share which he had in furthering the escape of Charles II. after the battle of Worcester. The king in his memoral wanderings was concealed for a night at the house of one of Mr. Hyde's tenants. But as this tenant was too hot-headed a royalist to be safely intrusted with the secret of his guest's quality, the king was accordingly passed off as a roundhead, and was in that character compelled to drink what must then have appeared hopeless success to the royal cause. The next day he having supplemented his sister's share of the house by Lord Southampton and Mr. Hyde, and by them safely conducted the next day to Shoreham, where they succeeded in procuring a passage for him to Fécamp. The circumstances are told in detail in a manuscript written by Mr-
Hyde's cousin Colonel Gounter, himself an actor in the casts. This manuscript now deposited in the British Museum, and contains the only authentic account of the escape of the king. There are notices of it in Jesse's "History of the Stuart"; and in Parry's "Account of the Coast of Scotland". In 1840, De Lacy, in "The Restoration," be, the only son of William John Grange, the negotiator between General Monk and Charles II. for the restoration of the king; and died in 1892. His granddaughter married Mr. Root, a Somersetshire gentleman, in whose family the estate still continues.

HYDRASTIS. (Warner, P. C.)

A genus of plants belonging to the natural order Umbelliferae, and to the sub-order Orothoraceae. It has the tube of the calyx rather compressed, the limb with an obsolete margin, the petals ovate, entire, acute, with a straight apex; the fruit flatly compressed from the sides; the carpels without vitre; the 5 ribs or nerves nearly sliform, the carinal and lateral ones usually obsolete, and the two intermediate ones joined. The species of this genus are generally bog-herbs; but few of them are under-shrubs. The umbel is single, surrounded by a few-leaved involucre. The flowers sessile or pedicellate, white.

Of 90 species of plants have been referred to this genus. It is not however improbable that a more attentive study of them will lead to the distinction of other genera amongst them.

This plant has peltate, orbiculate, double crenate leaves; the umbel capitata, of 5 flowers, often proliferous; the fruit smooth. This plant is a native of Great Britain and throughout nearly the whole of Europe, in marshy boggy places, and in the rocky crevices in the sides of mountains. It is called "Pennywort", on account of its leaves lying flat on the ground and having the size and form of a piece of money. It is also known by the names of "veiled-pennywort", "white-rayed", "sluice-wort", and "sheep's-lane." These latter names it has obtained on account of its being supposed to produce the rod and other diseases in animals that feed on it. This is, however, an error, as this plant will not produce disease in animals, but it occurs in damp moist situations, where animals that feed are likely to be attacked with rod and other diseases. It is in this way that other marsh plants, as the species of Drosera and Pinguicula, have been supposed to cause disease in sheep and oxen.

The large number of species of this genus few if any are used in the arts or medicine, and none of them are sufficiently ornamental to lead to their cultivation. H. Ascotiana is said to be used in India as a diuretic and occasionally as a culinary vegetable. H. umbellata is recommended by Martin as a diuretic for the same purpose. This is the only question that is not stated. The fresh juice acts as an emetic. It is said to possess an aromatic odour and an agreeable taste. The species of Hydrocotyle are easily cultivated; they must all be kept moist, no water whatever being given; some kinds should be grown in pots placed in pans of water.

(Don, Gardener's Dictionary; Burnett, Outlines; Babington, Manual of British Botany.)

HYDROCYANIC ACID. (Frassic Acid, P. C. S.)

HYDROSTATIC BED. (Bentladel, P. C. S. P.)

HYDROMETRY is that part of natural philosophy which relates to the determination of the humidity of bodies, particularly of the atmosphere; it comprehends also the theory of the instruments which have been invented for the purpose of ascertaining the quantity of water contained in a given volume of air.

The experiments of Dr. Dalton have proved that the water received from the earth is not dissolved in the atmosphere, and that it exists there in the form of vapour. That philosopher discovered also that the quantity of vapour contained in a portion of the atmosphereReadable, precisely upon the temperature of the latter, and that it is very variable even when the temperature is constant. He ascertained moreover that when a quantity of vapour is, at a given temperature, diffused through any space, it will support the same external pressure, whether previously that space had been void or occupied by air. On these principles are founded the methods which have been used for determining the absolute quantity of moisture in a given volume of air by means of the hygrometer: the requisite data being the elasticities of aqueous vapour at different temperatures, and the corresponding indications of the instrument.

The tension or elasticity of watery vapour corresponding to every degree of Fahrenheit's thermometer, the temperature being 0°, has been determined by Dr. Dalton for the purpose of reducing a small quantity of water into the vacuum of a barometer, and observed how much, at different temperatures, the vapour arising from it depressed the column of mercury; and a table of such tensions is published in the fifth volume of the 'Manchester Memoirs.'

Previously to stating the manner of determining the relation between the indications of an hygrometer and the quantity of aqueous vapour in respect to temperature, it will be proper to notice the following circumstances:—When an hygrometer, like that of Sauasseur or De Lec (Hygrometers, P. C. S.), is introduced in a close vessel, or in any part of space fully saturated with aqueous vapour, it is observed that, whatever be the temperature, the index points to the same graduation; from which it may be inferred that equal quantities of vapour have been absorbed by the material (hair or whalebone) of which the instrument consists, notwithstanding the difference of temperature. In fact the vapour in the vessel, or spaces, is in such a state that the presence of a material having the least affinity for water, is sufficient to produce a diminution in theelasticity of the material: the quantity thus absorbed is necessarily constant, unless the affinity undergo some change by a change of temperature; but each material of which the instrument is made is not sensibly altered by such change within the limits of the usual thermometric scale. When the vapour which the hygrometer is introduced is not completely saturated with water, the quantity of water absorbed by the hygrometer is limited by the power of the latter to absorb the precipitated moisture: that power diminishes in proportion to the quantity received, so that the affinity of the material for water ceases to act when it is equivalent to the pressure which the vapour can support without becoming liquid; and the elongation of the hair or whalebone then ceases, or the index remains stationary on the scale.

In order, then, to determine the law according to which the affinity of the hygrometric material for water diminishes as the precipitated water is absorbed by it, or, in other words, to find on the scale of the hygrometer a number of points corresponding to any given elasticities of the vapour, Gay Lussac put water into a vessel of glass; and, having determined the elasticity of the vapour rising from it, he suspended from the upper part of the vessel, a delicate and very sensitive barometer, the circumference of the graduated ring which served as a scale; this point thus became an indication of the elasticity of the vapour. Experiments of the like kind being made with vapour of equal temperature, but in different states of elasticity, between those which correspond to extreme dryness and complete saturation, there were obtained so many points on the scale of the instrument as indications of the elasticities of the vapour.

From the results of these experiments M. Biot found, by interpolation, a table of the elasticities of vapour for every degree of Sauasseur's hygrometer, the temperature being 0°, the centigrade scale being adopted (Gay Lussac, Table of Hygrometers, liv. i. ch. 13); but the elasticities or tensions would be more conveniently expressed in terms of the elasticity at the point of complete saturation, which is then represented by unity.

The numbers in the table are formed from the observed tensions at a constant temperature equal to 50° (Fahr.) and it has been supposed, that the index of the hygrometer stands constantly at 100° when the material is exposed to vapour in the state of maximum tension whatever be the temperature, that the index should stand at one point on the scale when the tensions of the vapour have the same proportion to...
the maximum tension at their respective temperatures; this
supposition is not quite correct; but it may be presumed that,
in using BIOT's table for temperatures differing from 50°
(Fahr.), the errors in the tensions will not be considerable.
Gay-Lussac having proved that vapours, whether those of
pure water or such as consist of different kinds intermixed
while they retain their character of elasticity, suffer the same
variations of volume by variations of pressure as are suffered
by permanently elastic fluids, determined, by subsequent ex-
periments, the volumes of the vapour produced by a given
weight of water at given temperatures and under given atmos-
pheral pressures; and thus, consequently, obtained the quan-
tities of water in a given cubic inch, the results of his experiments were reduced to a formula by BIOT;
and subsequently, with certain modifications, to one in English
weights and measures by Dr. ANDERSON, the writer of the
article on Hygrometry in the 'Edinburgh Encyclopedia'.

This formula is

\[ G = \frac{447}{4} + t \]

in which \( G \) is, in grains, the quantity of moisture in a cubic
inch of vapour at the temperature represented by \( t \) (Fahren-
heit's scale), \( P \) is the elastic force of the vapour at the same
temperature, and \( B \) is the height of the barometrical column
in inches at the time of the experiment. It agrees nearly
with what has been obtained by DALTON, from experiments on
the state of the thermometer at the dew-point [J. of Eco-
nom. P. C.], the height of the mercureial column in that
result being 30 inches. From this formula, the temperature \( t \)
being 30 inches, and \( P = 0.375 \) (from DALTON's table of the elastic force of vapour corresponding to
that temperature and that density of the air), we have

\[ G = 0.02477, \]

the grains of moisture in a cubic inch of the vapour.

The value of \( G \) being thus found for any given states of
the barometer and thermometer; the weight of moisture, in grains,
in a cubic inch of air of the like density and temperature, and
corresponding to the observed degree of SAUSURO's hygrom-
eter may be obtained on multiplying that value by the
number in BIOT's table corresponding to the observed degree
and dividing the product by 100; this division must be made
because, in that table, 100 represents the elastivity of the
vapour when in the state of complete saturation.

The extreme points on the scale of an hygrometer acting
by the elongation of a material, like those of SAUSURO and
DE LEO, may be found in the following manner: the instru-
ment is to be placed under a receiver in which is a certain
quantity of dry cesitic alkali; when, after a time, the material
will contract in length as much as its nature will permit; the
point on the scale at which the indicator stands is that of extreme
dryness, and constitutes the zero point. The instrument may
then be placed in water, or in a receiver filled with vapour
containing moisture, with the material, when the material
will expand to the great extent permitted; the place of the
index is then to be considered as the point of extreme
humidity, and is usually indicated by 100.

The lower consists of a glass tube bent so as to
form two equal branches parallel to each other, and each
terminating with a hollow ball in which is introduced sul-
phuric acid, coloured. One of the balls is covered with
cambic, which is kept constantly moist by water from a
neighbouring vessel; and the evaporation of the water, by
cooling that ball, allows the air in the other, by its superior
elasticity, to depress the acid in the tube below and force it
to rise in the other. The degree of evaporation depends
partly on the temperature, and partly on the state of the
surrounding atmosphere with respect to humidity; and hence
the depression of the acid in the tube, being measured by a
convenient scale, affords an indication of the relative dryness
of the air. In order to determine the absolute quantity of
moisture in a given volume of the atmosphere by the state of
his hygrometer, Leslie, having found from some experiments
that 4 grains of water (calculated to the volume of 1 ounce
of water, and having ascertained that the quantity of caloric necessary
to convert a given volume of water into vapour was expressed by
6000 degrees of his instrument; concluded that the same
quantity of caloric would raise an equal volume of air to
the temperature expressed by \( x \times 0.000, \) or 16,000 degrees of the
instrument; and consequently that, at the temperature of the
wet air, the atmosphere contains a quantity of moisture
equal to that of the weight of one 4 grains.

The scale between the points of extreme dryness and external moisture
being divided into one thousand parts. (Textual 'On
the Relations of Air to Heat and Moisture.'
)

From the fact that the elastic forces of pure vapour and of
vapours mixed with atmospheric air are equal to one another,
the expression of the forces in a given volume of air is thus
saturated with moisture may be found. For if \( V \) represent
the given volume of dry air, \( V' \) the volume, when saturated,
and \( B, \) in inches, the height of the barometric column;
then the whole force of the air under the increased volume

\[ V = V' \]

Now \( P \) representing the elastic force of the vapour
in inches of mercury, which, for the given temperature,
may be found from DALTON's table; the sum of the elastic
forces of the air and vapour will be expressed by \( F + P \);
and this being made equal to \( B, \) the pressure of the atmos-
phere, the value of \( V' - V \) may be found. Making \( V' = 1, \)
that value expresses the expansion in a fractional part
of the volume of dry air.

At any place on the surface of the earth, the mean tem-
perature at which moisture begins to form in the atmosphere
may be found from DALTON's formula \( E = \frac{4}{10} M (F - P), \)
in which \( E \) is the number of grains evaporated in one minute
from the surface of water in a cylindrical vessel 1 inch in
diameter and one inch deep, \( F \) is the elastic force of vapour
in the atmosphere at a given temperature, which may be the
mean annual temperature at the place (50° Fahr., for Great
Britain; 60° for tropical climates) and \( P \) the elastic force expressed as
the moisture begins to form: \( M \) is, in grains, the evaporating
force in an atmosphere supposed to be perfectly dry; and
DALTON has given a table of such forces for different tem-
peratures, and for moisture being at rest, after the wind
had ceased its motion. In the table, the temperature being 212°,
the height of the barometrical column 30 inches, and the wind blowing
moderately, the value of \( M = 154; \) and substituting this value in
the formula, we have \( F' = F - 1 E. \)

The mean annual evaporation in Great Britain is 0000456
inches or 0.0116 grains per minute; this last number being
multiplied by the area of a circle 6 inches in diameter, gives
0.0232 grains per minute (16 E) for the evaporation in
Great Britain, and hence \( F' = F - 0.0647. \) But, by DALTON's table,
the elastic force \( F \) of vapour at a temperature equal
to 50° is expressed by 0.376 in inches of mercury; hence
\( F' = 3103 \) inches. Substituting in the above formula for \( G \)
this value of \( F' \) in place of \( F, \) and 30 inches for \( B, \) we get
00205 for the number of grains of moisture in a cubic inch of
air corresponding to the elasticity \( P \); the number cor-
responds to the temperature 44° 16'; which may be found by
inspection in a table formed to contain the values of \( G \)
for different degrees of temperature.

HYGOMAS, or scales from Hygrometrica, in reference to its twin
leaflets, a genus of plants belonging to the natural order
Leguminosae. It has a calyx furnished with two bracts
at the base; the tube turbinate, coriaceous; the limb 4-5 parted,
diadelphous, the lobes sometimes united in pairs, the
sepal nearly equal, glandular; 10 stamens distinct, inflated
in the middle; the style filiform; the legume woody, oblong,
many-seeded, containing fecula; the embryo straight. The
species are trees, with laticiferous leaves, and coryls of white
or yellow flowers.

H. Courbaril, Locust-tree, or Gum-Annine Tree, is an oblong
ovate leaflet, unequal-sided, and unequal at the base, ending
in a long point; with the legume oblong, compressed, yel-
wobish, shining. It is a fine lofty spreading tree, and grows
in the tropical parts of America and in Jamaica. The seeds
are enveloped in a cellular mealy substance, which is sweet
like honey, and is eaten by the Indians with great avidity.
When fresh it is slightly purgative, but by keeping it loses
this property. A decoction of this substance, when allowed
to ferment, forms an intoxicating drink resembling beer.
From between the principal roots of this tree there exudes a
fine transparent resin, with a red or yellowish red colour, and
which is collected in large lumps and sold under the name of
Gum Annine or Gum Animal. This resin resembles amber,
and is very hard, and sometimes containing carbonaceous
lumps imbedded in it, which remain in a perfect state
of preservation. It burns readily, emitting a very fragrant smell.
Dissolved in alcohol it renders the wine of a dark kind of
varnish. According to Lindley, this resin is called
Jatnha, Jatkh, or Copal, and in Minas Gerais Jatoba.
Courbaril is the name of the tree in some parts of South
America. In countries where this tree grows the resin is
used medically, and has also been employed in that way in Europe. It acts as a stimulant when taken internally, and as an irritant when applied externally. In fumigation it has been employed for persons labouring under asthma and dyspepsia.

Dissolved in spirits of wine or oil it is used as an emulsion in rheumatism. Internally, it has been much employed as a substitute for guaiacum, in venereal disease and chronic rheumatism. The inner bark, either in the form of tincture or decoction, is administered as a vermifuge. The curnudes have a method of mixing it with sugar and rum, so as to make a very agreeable emulsion or syrup. The wild bees are fond of building their nests in the trunk of this tree. The timber of the old trees is very hard and tough, and is in great request for wheelwork, particularly for cogs. The wood is so heavy that a cubic foot is said to weigh a hundred pounds; it takes a fine polish.

Several other species of Hypholoma are described, but of them positively little is known.

(Doen. Gardener's Dictionary; Lindley, Flora Medica.)

HYMENOMYCETES, the first suborder of the Fungi, a natural order of plants. (Fries, P. C.) They are characterized by their reproductive organs, called the hymenium, being naked. This suborder is divided by Fries into four tribes (Fussor, P. C.); by Berkeley into six tribes. Those of the latter are, Pilati, Clavati, Miroti, Cupulati, Tremolinit, and Sclerotiacei.

The tribe Pilati contain the following British genera:—

*Agaricus*, in which the hymenium consists of plates radiating from a common centre, and with short or long, from the interior, composed of a double closely connected membrane, more or less distinct from the piebus: the veil is various or absent. (*Agaricus*, P. C.)

*Cantharellus* has the piebus furnished below with dichotomous, radiating, branched, subparallel folds, not separable from the flesh, sometimes anastomosing or obsolete.

*Molcinus* has the hymenium velvety, or simoom-pileate; the folds not distinct from the flesh of the piebus, forming unequal or fithickorous pores. (*Molcinus*, P. C.)

*Schizophyllum* has the gills radiating from the base, composed of a folded membrane, which is ruptured along their edge; the two portions of the fold being revolute, bearing a cary or are; on the outer surface.

*Dedalus* has the hymenium composed of anastomosing gills, or numerous elongated pores formed out of the cory substance of the piebus.

*Polyporus* has the hymenium concrete, with the substance of the piebus consisting of subrotund pores with their simple dissections.

*Bolus* has the hymenium distinct from the substance of the piebus, consisting of cylindrical separable tubes, with oblong sporela. (*Bolus*, P. C.)

*Gyromitra* has the hymenium formed of a distinct substance but concrete with the fibres of the piebus; the tubes at first wart-like, somewhat remote, closed, radiate-fimbriate, at length approximated, elongated, open. This is the most perfect of the hymenium of the same substance as the piebus, composed of free spore-like processes.

*Stielleichtas* has the hymenium somewhat distinct from the piebus, composed of irregularly disposed, curved, and gyrose amelante teeth.

*Irpes* has the hymenium concrete with the substance of the piebus, torn into distinct spines, disposed in rows or in a reticulated manner, their bases connected together by lamellae, sinuous, or poro-foveal; the saci slender, situated only on the toothed processes.

*Radius* has the hymenium tuberculated; the trabes serrated, resembling papille or rude somewhat angular spines, more or less obtuse, distinct or irregularly fasciculate, the inner substance homogeneous with the receptacle; the saci occupying indifferently all parts of the hymenium.

*Phallus* has the hymenium homogenous and concrete, with the piebus smooth, venoso-rugeous, wrinkles interrupted, disposed irregularly, straight or flexuous, bearing saci all over.

*Thelephora* has the hymenium homogenous and concrete with the piebus, even or papillate, the whole surface bearing saci.

Of these genera Agaricus contains by far the greatest number of species. On this account it has been found necessary to class the species under various subgenera. The following table contains the subgenera of Fries arranged in eight series.

P. C. S., No. 94.
D. mucronatus is a northern plant. It yields an agreeable perfume.

Upwards of forty species of the genus Polyergus are found in Great Britain, and many more European species have been described. The species are known in arts and medicine. P. ignarius has long been famed as a styptic. Amadou, or German tinder, is made from this plant by separating the porous hymenium from the harder parts and steeping it in a solution of lime. It has been hitherto used in a soft sponge state. Many other species of Polyergus may be used for the same purpose. The Laplanders also use them for making the actual cautery in the same way as the Japanese and Chinese use them. When they have made a wound in the limbs, they pull the fungus in pieces and placing it on the skin, set fire to it and allow it to burn away till it blister the skin, when it acts as a counter-irritant. P. officinalis is a cathartic. P. mucronatus has a pleasant smell. Some of the species secrete acids, and boletic, fungic, and axillary acids have been obtained from them. P. sepium is the largest of the British fungi, weighing sometimes as much as thirty pounds. P. destructor is one of the fungi found on decaying timber when it is attacked with what is called dry-rot. Many of the plants formerly included under the genus Boletus are now referred to Polyergus. Berkeley enumerates sixteen species of the genus Boletus as natives of Great Britain. [Boletus, P. C.]

The genus Hydnium, although named after Seve, the true name of the sevens, is divided into several species. The hymenium is composed of shiny bodies which give to the species of this genus a very formidable appearance. Hence they are called in the country spino-stools, prickle-stools, &c. Several species are esteemed in Great Britain. Some are eatable, but others should be used in their selection. De Candolle says that those which have a dark colour are dangerous.

The genus Fuscina, with one representative in Great Britain, F. hepatica, the pipe-stool. It grows upon the trunks of old oaks and other trees. It is eaten in France. When cut into it is beautifully marked with red and white streaks resembling a fine piece of beef. It is called in France Foie d'Herbe or Foie de Chêne, &c. It has an acid taste, but is rather tough. It has been known sometimes to attain the weight of thirty pounds.

The genera Sistotrema, Trusca, Radulium, and Phlebia are small genera, and not used as food, or in any other way. The species Thelothora is an extensive genus, and forty-two species are indigenous in Great Britain. They are common on decaying branches of trees, &c., and exhibit a variety of colours.

The tribe Clavarii, which are distinguished by a single or branched vertical receptacle, embrace the following British genera:—Clavaria, Cetraria, Geoglossum, Spathularia, Myxtrula, Typhula, and Pollacillaria. These plants, in their texture and club-shaped forms, resemble the corals, and were actually placed by the older naturalists in the same class. Some of the species of the Clavaria are edible. All the Clavaria are esteemed as food. C. rugosa has an agreeable flavour, and is a favourite of the common people. C. pyxidata are prized on account of their taste. C. cinerea is the species most commonly eaten on the Continent.

The tribe Mitrati have a bulbous, fleshy, margined receptacle. They embrace five British genera:—Morechella, Hetoidea, Vomps, Leotia, and Vibriessa.

The genus Morechella yields the excellent fungus morel. [Morechella, P. C.]

Three species are found in Great Britain. There are also three British species of Helvella as that genus is at present defined. The species of Helvella are edible. H. crispa is considered the best species for eating, but none of these are of great or British, nor poisonous.

The tribe Copulatii, which has a sessile marginated receptacle with a superior hymenium, contains the following British genera:—Peziza, Patellaria, Azcoholia, Burgaria, Dictodium, Tympanum, Conioporus, Stictia, Cryptogenus, Cyphella. Of these Peziza is the most extensive genus, containing upwards of 300 species, of which 106 are natives of Great Britain. Some of these plants are very remarkable from the supercilious and club-shaped forms, resembling the corals, and being actually placed by the older naturalists in the same class. Some of the species of the Clavaria are edible. All the Clavaria are esteemed as food. C. rugosa has a agreeable flavour, and is a favourite of the common people. C. pyxidata are prized on account of their taste. C. cinerea is the species most commonly eaten on the Continent.

The tribe Mitrati have a bulbous, fleshy, margined receptacle. They embrace five British genera:—Morechella, Hetoidea, Vomps, Leotia, and Vibriessa.

The genus Morechella yields the excellent fungus morel. [Morechella, P. C.]

Three species are found in Great Britain. There are also three British species of Helvella as that genus is at present defined. The species of Helvella are edible. H. crispa is considered the best species for eating, but none of these are of great or British, nor poisonous.

The tribe Copulatii, which has a sessile marginated receptacle with a superior hymenium, contains the following British genera:—Peziza, Patellaria, Azcoholia, Burgaria, Dictodium, Tympanum, Conioporus, Stictia, Cryptogenus, Cyphella. Of these Peziza is the most extensive genus, containing upwards of 300 species, of which 106 are natives of Great Britain. Some of these plants are very remarkable from the supercilious and club-shaped forms, resembling the corals, and being actually placed by the older naturalists in the same class. Some of the species of the Clavaria are edible. All the Clavaria are esteemed as food. C. rugosa has a agreeable flavour, and is a favourite of the common people. C. pyxidata are prized on account of their taste. C. cinerea is the species most commonly eaten on the Continent.
about the axis, it would describe the surface. Consequently
a straight line revolving about an axis which is not in its
plane, describes a single hyperboloid of revolution. This
surface is therefore easily turned: the outside of a dice-box
may be considered as a species of it.

HYPERICUM, a genus of plants belonging to the natural
order Hypericaceae. The calyx is 5-parted, or it has 5
sepal; 5 petals; 3 styles, and a 3-celled capsule. The flowers
of the species are mostly yellow. There are 13 British species
of this genus, and 172 are enumerated by Don as growing in
various parts of the world: St John's Wort is the common
name of all the species.

H. brachyodes has an erect quadrangular stem, elliptical
ovate obstate leaves with a few pubescent dots, reflexed ovate
lanceolate sepals having pubescent stigmas, obsolete petals
with purple streaks and dots beneath. It is the H. quadrangular
of Fries, and is found in most parts of ditches and rivers.

H. perforatum has an erect 2-edged stem, ovate or ellipti-
cal leaves with numerous pellicid dots, anthers with black
dots, the styles as long as the capsule. It is found in large
clusters, in the plains belonging to the coasts of Asia and
Africa. The flowers are of a bright yellow colour, dotted
and streaked with purple; when rubbed they emit a
powerful lemon-like scent and stain the fingers with dark
purple. This is one of the plant constituting purple vola-
tile oil, which is aromatic and possibly astrin gent, though as yet it
has been but little used in medicine. Its sensible qualities
have been described as a balsamic, one being expressely
official, entitles its virtues to a further trial. When boiled
with alum this plant yields a yellow dye which is used for
colouring wool. The common people of Germany and France gather
this species of St John's Wort with great ceremony on St.
John's day, and hang it in the windows and about their houses
as a charm against evil spirits, storms, thunder, and all other
calamities, mistaking the meaning of some medical writers
who fancifully called the plant Fire Demonus, from a
notion that it was a remedy in maniacal disorders. At one
time the people of Scotland used to carry it about their
persons as a protection against witchcraft and enchantment,
and they fastened green sprigs of it to the top of their
knives, entitling its virtues to a further trial. At this
moment it is little used except in the dress of the lower
classes. Cows and goats will eat the plant, but horses and
sheep refuse it. It is the Hypericum of Dioscorides (iii. 162).
It is also used in the dress of the lower classes.

H. laurinum has a smooth herbageous stem, rather dis-
tant obstate leaves, full of pellicid dots; the lower leaves
narrow and lanceolate, segments of the calyx equal, nearly
linear and acute. It is a native of Brazil, in the provinces of
B. Paul and Minas Geraes, where a decoction of the leaves
is used as a remedy against the bites of serpents.

H. crispinum has a round branched stem, sessile lanceolate
leaves, small and oblong. The leaves have a base full of dark
brown oblong and rounded sepals. It is native in the regions of the Mediterranea,
and is the Hypericum of Hippocrates (Morb. Mul. i. 610); also of
Dioscorides (iii. 161), and the Hypericum quad ad chamapi-
num of Theophrastus (iii. 168). It is used in commerce as a
harmful weed.

At the present day it grows near the sea in Attica.

H. perfoliatum, the JVperoumof Dioscorides (iii. 163).
It has a 2-edged stem; oval, clasping, dotted leaves; fringed
along the margins, large pointed sepals and petals, and sessile flowers.
It is a native of Italy.

H. Corsi has a shrubby erect round stem, linear leaves
in whorls with acute margins, and a bluish linear calyx. It
is the species of Dioscorides (iv. 174), and the Coris of
Pliny (xxvi. 3). This species is a pretty little shrub, native of
the Levant, and in dry places in the south of Europe.

H. Origineum is distinguished by its ascending down-
stem, oval blunt and subcordate leaves full of pellicid dots,
numerous stamens, and many black dots in the corolla. It
is a native of the East, about Constantinople, Thrace, and
Armenia, and is frequently found on high mountains in comp-
any with H. perforatum. It is probably the "Hypericum
officinale" of Dioscorides (iv. 6), and undoubtedly the Ageratum of Pliny
(xxvi. 4).

H. Olympicum has elliptical lanceolate leaves full of
pellicid dots; a round stem, and whitering corolla and stamens.
It is a native of Mount Olympus and of China. Fries thinks
it probable that this is the "Hypericum officinale" of Dioscorides (iv. 6).

H. crassocephalum is found in mountainous parts of
Greece, on the Rupheian mountains, and is remarkable for
its large sized white flowers. The hardy herbaceous kinds will thrive in any
common garden soil, and are easily propagated by dividing the roots or by seeds.
Those set by the greenhouse of frames will thrive best in a mixture of loam, and
beauty and strike root readily in sand under a box. -J. flavissimus.

ICE-HOUSE, a building constructed for the purpose of preserving ice through the summer, by excluding, as perfectly as possible, all access of heat, and with it the moisture or humidity of the external atmosphere. Such structures are not only useful for preserving ice which is to be applied to the cooling of liquors, or to the preparation of articles of confection, but also as affording the most effectual means of cooling for keeping meat, fish, game, vegetables, and fruit: sweet and fresh in hot weather.

In Loudon's 'Encyclopedia of Cottage, Farm, and Villa Architecture,' where (sec. 736-738) a detailed account is given of various modes of constructing ice-houses, it is observed that although these important conveniences are rarely to be found among the buildings of an English farm, they are frequent in those of North America, and might be advantageously introduced in this country, especially upon such farms as are connected with inns. To a gentleman's country residence an ice-house is always an important, and, in some cases, almost indispensable appendage.

One of the simplest modes of preserving ice, alluded to in the work above mentioned, consists in enveloping the ice in a great quantity of straw, above the surface of the ground, in such a position as to moisture, which is even more injurious than heat, may drain off freely. For this purpose the ground should be raised into the form of a flattened cone, upon which should be laid a stratum of straws. Straw is laid upon the straws to the thickness of four feet, the interstices of which have the effect of keeping a stratum of confined air round about the pile of ice; and finally two or three feet of straw arranged as a hatch. The best situation for such an ice-stack or mound is stated by Loudon, to be under the shade of trees, or, where such shelter cannot be obtained, under a kind of shed roof, with an opening to the north only. Some writers, however, among whom may be mentioned Cobbett, who notices the subject in his 'Cottage Economy,' considers that, in consequence of their tendency to increase the humidity of the air, the vicinity of trees is objectionable.

On the same principle some recommend an eastern or south-eastern, in preference to a northern aspect, for the entrance to an ice-house, in order that the morning sun may dissipate the damp air from it.

An underground ice-house may, according to Loudon, be started in a large pit, with hollow or double walls, floor, roof, and doors, and furnished with a compact drain to allow the escape of such water as may be produced by a partial thaw, without admitting any air. Such ice-houses are usually formed in the shape of a hollow mound, with a surface of about five feet square, and a few feet in depth. It is the opinion of Mr. David Gordon, for constructing an ice-house of the simplest form, principally of timber. In this plan the enclosure is made considerably larger than the ice-house, which consists of a framework of strong timbers, roughly boarded outside, and lined with straw set on end and confined by battens nailed to the timbers. The conical roof is thatched with straw or heath, and the space between the outer boarding and the surface of the enclosure is filled with heath, brushwood, or fir-trees, and neatly thatched or turfed over.

In some situations simple excavations in calcareous soils, with a long circuitous passage by way of approach, are used instead of more regular ice-houses.

In filling an ice-house, the ice should be broken with mallets to a coarse powder, which, according to Loudon, should be composed of particles not larger than those of sand or salt, and well mixed with straw and nicely rolled into the ice-well; its upper surface being kept of a concave shape, and a little water being occasionally added to fill up all interstices, and to facilitate the congelation of the whole into a solid mass. A better method, according to the same authority, is to sprinkle the ice with water saturated with salt, by dissolving it at the rate of a pound of salt to a gallon of water. This salt and water may be applied by a common watering-pot upon the surface of the ice at intervals of two feet from bottom to top of the mass, an extra quantity being poured on when the filling is completed. By this means the ice becomes so firmly compacted as to need the force of a pickaxe to break it up, in the heat of summer.

From the Gardeners' Magazine,' it will be found to keep three times as long as by the common method in the house, and it will also keep three times as long when exposed to the air, from salt water, and consequently salted, having a large capacity for heat than fresh water or fresh ice. Snow is occasionally preserved in a similar manner to ice, being packed into the ice-well and covered over, it being considered that the ice and snow for refrigerating liquids, in ancient as well as modern times, are given in a long paper in the third volume of Beckmann's 'History of Inventions.' (English for that or the other. A reference is made to antiquated authors who allude to the preservation of snow in pits or trenches; and it is stated that a
similar method is pursued in Portugal, where, when the snow has been collected in a deep gulf, some grass or green sod, covered with dung from the sheep-pens, is thrown over it; and under this covering the snow is so well preserved that it may be taken up and transported to a considerable distance throughout the summer.

In connection with the subject of this article, London de-

scribes a watch-case he intended to serve some of the pur-

poses of an ice-house, in which the evaporation of water, constantly trickling down the outside of a close conical cham-

ber elevated above the ground, is employed as a means of refi-

ting; and also, he says, in his 'First Additional Supplement,' an ice-box which might almost be termed a portable ice-house. It consists of an inner and outer box, six inches apart, the interval between which is filled with burnt cork reduced to powder, this being found to possess higher non-conducting properties than the charcoal of wood.

The lid is double, and is filled with the same substance;

and it is made perfectly air-tight by means of project- ing ledges, which, when shut, dip into a gutter filled with water. Ice may be preserved for several weeks in such a box, in which also bottles, dishes, &c. may be placed. Simi-

lar to this contrivance is, the American ice-safely lately intro-

duced into this country.

ICE-PLANT. [Membranacea, P. C.]

ICHNEUMON, a genus of insects belonging to the order Hymenoptera, and the family Psychidae, in the arrangement of Latreille. The genus, as defined by Linnaeus, included such pugnacious hymenoptera as are furnished with veined wings (the anterior pair present in their place, and a closed or cut-off membrane); the ovaries of the females being furnished in a great degree with articulations, and an ovipositor of various length and complicated structure. The Linnean genus now constitutes a group in- cluding a great many well marked genera and an immense assemblage of species. All these are remarkable for the habits of their larvae, which are parasitic in the bodies of other insects. These bodies the perfect ichneumon perforate by means of their long and sharp anterior ends, and there lay their eggs. This destructive habit gave rise to the name by which they are known; a comparison being drawn between them and the Egyptian ichneumon (Viteura Ichneumon), the quadruped celebrated as the destroyer of serpents and crocodiles.

The history of these insects has attracted much attention among naturalists, and many elaborate memoirs have been written upon them. The purpose they serve in the economy of nature has been well described by Kirby and Spence:—

'The great body of the ichneumon tribe is principally em- ployed in keeping within their proper limits the immense host of lepidopterous larvae, destroying, however, many insects of other orders. Euxomis is the only ichneumon of the Ichneum-

onideae that scarcely any concealment, except perhaps the

waters, can secure their prey from them; and neither bulk, con- formity, nor mimicry can serve to terrify them from effecting their purpose. They attack the rathera small species of insects; they discover the retreat of the little bee, that for safety hides into timber, and, though its enemy ichneumon cannot enter its cell, by means of the long ovipositor itDisable the adjacent link.
Normal group. Acetabrobranchi. Fish breathing with gills, not by lungs. 4. Lophoniscus. Bony fishes breathing by the gills, but having a form. Mr. Macleay has not yet presented an analysis of the families and genera included under the above five orders, with the exception of those of the third, Osutopothyrid, a term by which he proposes to designate the osseous fishes having pectoral gills. The following table of his subdivisions of this important order will convey to the naturalist a clear idea of his system.

Tr. 4. Proteronecta. Vertical fins, when existing, inserted under the pectorals, and directly suspended to the bones of the shoulder.

Tr. 5. Alabonecta. Vertical fins, inserted behind the pectorals, and not attached to the bones of the shoulders.

Geographical Distribution of Fishes.—This branch of ichthyology is beginning to attract the attention and research which the interest of the subject demands. Within the last five years the example of Yarrell has been followed in many countries, and valuable local monographs published, with excellent illustrations. In the north of Europe, besides the writings of Nilson and Eckerman, the fishes of Denmark are in progress of illustration by Henrik Kroyer. Those of Belgium have been carefully examined by M. de Selys Longchamps. In that naturalist's Faune Belge fifty-three freshwater fishes are enumerated, of the forty-three, forty-two being fresh-water fishes of central Europe. They are distributed in the great lakes of the Scheldt as far as Antwerp. The fresh-water fishes of central Europe are the engaging attention of Agassiz, and his work on them is in progress of publication. Freyer has published an account of those inhabiting Carniola, amounting to thirty-two species. Italian ichthyology has been admirably illustrated by Charles Bonaparte, the Prince of Canino. In Asia the fishes of the Caspian have been described by Eichwald in his Fauna Caspia-Caucasia, published in 1846. Those inhabiting the rivers of Syria have been enumerated by Heckel (1843) from the collections of Kotsch. Fifty-seven species inhabit the rivers Orontes and Euphrates, of which no fewer than forty-five are Cyprinidae. Indian ichthyology has received valuable contributions from McClelland, whose papers have been chiefly published in the Calcutta Journal. In Sweden's 'Fauna Japonica' (1854) there are accounts and figures of Japanese fishes by Temminck and Schlegel. The most valuable contribution ever made to our knowledge of the ichthyology of Eastern Asia was communicated to the British Association at Cambridge in 1845, in the form of a report on the Ichthyology of China, by Dr. Richardson. From his researches it would appear that the fishes of that region are not only very numerous in regard to species, but also very valuable on account of their economic and medicinal properties. The above remarks on their distribution are highly interesting. It would appear that chains of islands or coasts having an east and west extension determine the extent of the range of species and groups of species. For example, to take the intertropical zone of the ocean in the lowest degree of latitude, the Nicobar group in the Red Sea, the coasts of Madagascar, the Mauritius, the Indian Ocean, the south of China, the Philippines, the Malay Archipelago, the northern coast of Australia, and the whole extent of Polynesia, while including the South Seas, presents a remarkable uniformity in the generic forms of the fresh-water fishes, China agrees with the peninsula of India. Were the vast zone in question, embracing more than two-thirds of the circumference of the globe, to be accurately described, we should find the remains of fishes similar everywhere throughout, the species which have a local distribution being few and unimportant. This result of Dr. Richardson's researches is of the highest importance when brought to bear on geological considerations. Dr. Richardson has also been engaged in the special investigation of the ichthyology of Australia, and his many valuable memoirs on that subject may be consulted in the 'Transactions of the Zoological Society,' and in the 'Annals of Natural History.' In Dieffenbach's Travels in New Zealand (1843), the same indefatigable and philosophic zoologist has published, in conjunction with Mr. Gray, a list of the fishes of New Zealand. Ninety-two species are there enumerated. In Smith's 'Illustrations of the Zoology of South Africa,' figures and descriptions are given of the fishes of the Cape of Good Hope. The researches of Dr. Peters of Sicily in the southern parts of Africa, at present in progress, promise to make us well acquainted with the ichthyology of that interesting region. With those of the northern part of Western Africa we have had ample information in the valuable memoirs of Lowe on the fishes of Madeira (Zoological Transactions and Proceedings).

The labours of Jentyns on the fishes collected during Captain Fitzroy's voyages have contributed materially to our knowledge of the ichthyology of the coasts of the South American peninsula, whilst that of Guiana has been illustrated by Sir Robert Schomburgk, in the Naturalist's Library. De Kay's Zoology of New York (1842) has been much noticed in detail with the fishes of the United States. They amount, so far as known, to 440 species, distributed through 166 genera and 39 families. In the State of New York there are 126 Acantopothyrid, 35 Malacopterygii, 18 Plectognath, 3 species of sturgeon, and 27 cartilaginous fishes. It is to be regretted that the researches of Dr. Parnell on the West Indian fishes are still unpublished, since they would go a long way towards enabling us to gain a connected view of the ichthyology of the new world. As far as we can judge from the materials as yet collected, the distribution of fishes appears to be determined by the same laws which regulate that of other aquatic animals. Climate, composition of the element in which they live (whether salt, brackish, or fresh), and conformation of the sea or river bed, on which the depth of water depends, are the great regulating influences. The greatest distinctions appear to be made between the fresh and salt waters, whilst the latter, on the contrary, are distinguished by many forms of fishes not found in the sea, and especially near the coast. As far as the distribution of fishes is concerned, the coast of the United States is for the most part distinct from those on our own side of the Atlantic. Some fishes have very limited ranges in depth compared with others, and, generally speaking, it may be assumed that those having the greatest vertical range (i.e., range in depth) have also the widest horizontal extension, a fact depending on the capacity of such species for living under a greater variety of conditions. Barriers of land, as chains of mountains, determining the courses of rivers, are often the boundaries between two distinct specific assemblages of fresh-water fish, and in like manner a very narrow strip of land may divide two very distinct marine faunas. The distribution of species affecting the distribution of numerous marine invertebrata which feed on those vegetables, and in their turn serve to furnish food for fishes, will materially affect the distribution...
of many species of the latter. So also will the presence of currents, and even the agency of man, assisting often unintentionally in the conveyance of ova from one country to another. Distant regions, presenting similar conditions, such as the Arctic and Antarctic seas, are inhabited by species recognized as identical, or nearly so. It is probable also that the fishes inhabiting the greatest depths of the tropical seas remain relatively immovable, and that those of the latter in like manner approach Arctic forms.

A brief glance at the range and distribution of the principal genera of fish will help to illustrate the problem.

The lowest and most anomalous of all the species of fishes, the Brochichotomus, is generally distributed through the seas of Europe. Only one species is known, yet we cannot but hope that the researches of the many active naturalists now occupied with the study of marine zoology will bring to light forms connecting the Lancetfish with other genera. The Myxine, or gluttonous hag, almost equally strange in form and structure, is confined to the most northern and most southern seas, and is replaced in the higher parts of the southern hemisphere by the equally curious and nearly allied genus Rpistreptoma. The Lampreys inhabit the fresh waters of Europe and North America, but the species in each are quite distinct. Lepadodi, the connecting link between fishes and reptiles, so dubious in organization that its position is still disputed, is an inhabitant of the west of Africa, and a genus characterized (1846) by Dr. Peters on the eastern coast of the same continent.

The rays and sharks are universally distributed, but many of the genera and species are very local and apparently regular in their distribution. It is a fact of vast importance that the southern hemisphere can boast of the greater number, though fortunately the most formidable of the species are exotic. The largest species, as the great Sphéthas marinus, the basking shark, are harmless, and have their favourite habitations in the temperate zone. Size among fishes does not appear to have any relation to latitude. Chimaera is northern and southern, extending from the frigid zone. The Scyliorhiza are for the most part southern and tropical, especially the curious forms of Cestracion and Austracion. Monacanthus inhabits the American and Chinese seas; Triodon, the Indian ocean; Tetrosdon, Diodon, and Bulistes have wider ranges. The typical genus of pipe-fishes, Synemys, is cosmopolitan, and has a very wide geographical distribution. Six species are found in the British sea, two on the coast of the United States, and Mr. Jenyns has described new forms from Valparaiso, Tahiti, and Patagonia. Hippocampus is of the temperate zones of both hemispheres, and in the tropical seas is replaced by Solenostomus and Pogonias. The sturgeons inhabit the Western Hemisphere, the Black sea, and the Mediterranean. Three species are Northern European.

Of the cels, Anguilla, Conger, and Murana are typical and cosmopolitan. Gymnarchus is Egyptian, Gymnotus (the electric eel) is American, both inhabiting the fresh waters of both hemispheres. The common flat fishes are very generally distributed; the largest species is inhabiting of northern seas. The Mediterranean boasts of many species of Pleuronectes. Species of sole are found in both northern and southern hemispheres. The Gadidae are inhabitants of northern and temperate seas, and certain species, as the Tusk, do not range farther southwards than Norway and Scotland. Lepisosteus, one of the few remaining genera of Sauroid fishes, which appear to have played a most important part in the waters of ancient geological epochs, is confined to the rivers of America, and some allied forms to northern Africa. The herring tribe, Clupeidae, has a wide distribution of the typical forms in the southern as well as in the northern hemisphere. The species however are locally distributed; thus the true herring is unknown in the Mediterranean, where its place is taken by the horse mackerel and herring. The American coast herring is very distinct from those of the north. Even within very limited areas, as in that of the British seas, the species have peculiarities of distribution, as we see in the prevalence of the herrings of the northern coast and the southern coast. The horse mackerel is restricted to the south coast of the Irish sea, while it is replaced by the Pilchard on the south-west coast of England and south of Ireland: the white-sait is also a remarkable instance of local distribution. Mormyra, Esox, and Lepisosteus are American, the first in North African; the flying fishes are oceanic and Mediterranean, and the pike proper are inhabitants of the temperate zones. The restricted genus Esox is confined to fresh water.

The important family of Salmonidae has its most valuable members in northern regions, some with a wide range, the same species of trout occurring in Lapland and in Switzerland. In North America, forming the general aspect very similar, depending on characters of form and colour, &c. It is probable also that the fishes inhabiting the greatest depths of the tropical seas remain relatively immovable, and that those of the latter in like manner approach Arctic forms.

Among the most characteristic fishes of the fresh waters of tropical countries are the Siluridae, which abound in the regions of Central Asia, where almost all the species of the typical genus Silurus occur. A single offset finds its way to Europe. Pimelodus and Cichlithys are American genera of this family; the electrical Malapterurus, North African; Loricari, South American. Equally interesting and well marked in distribution is the fresh-water family Cyprinidae. The true carps are characteristic of the old world; Catostomus and Analalapi of the new.

The common food-fishes of the northern seas, Myxine, Lophius, and Harengus, are chiefly represented in Africa and South America. A single Lophius is a native of Europe, but the species show a distribution like that of Lepisosteus as inhabitants of the United States, and Richardson has described some Australian species. The Goby tribe prevails in Europe and Asia. Some of the species of Gobius are remarkable for the depth at which they live. The Blennies are truly European, with very few exceptions. The Gurnards are mostly of northern seas. Some species of the Goby tribe inhabit fresh water, as the genus Thymichoides, which is found in marshes in India. Coniprurus lives in Lake Baikal, and one or two species of Gobius proper live in rivers.

The Mugilidae are very generally extended. They have been said to be absent from North America, but this is incorrect, four species of Mugil inhabiting the United States. Alburnus is also a cosmopolitan genus.

The Gadidae and Pharyngidae are essentially tropical, being all natives of the eastern regions of Asia. Their organization is peculiarly adapted to their climatic range. The Tetraodon are fishes of warm climates, and many species inhabit the Antarctic seas. Many species of species of Pomacentridae inhabit the southern seas, and the allied typical genera of the tribe are essentially cosmopolitan. The Cestridae are essentially aquatic.

The family of Sparidae gives the most prominent feature to the ichthyology of the Mediterranean and seas of Southern Europe. Porgius has a wide range, but chiefly through warm regions. The Sciaenidae, very numerous in species, are mostly eel-like. The important family of Trigidae, of which Gurnard is the type, has a very extensive distribution. The true gurnards are mostly European; Scorpina ranges from Europe to Australia. Platypogon is peculiarly Indian. Scolopsis is a genus of the old world, with one or two exceptions.

The Percidae, chief of the Acanthopterygidae, is partly composed of marine and partly of fresh-water genera. The genus Percus is characteristic of the northern temperate zone. Most of the species of Gobio, and Serranidae are cosmopolitan. Mullus and Paralichites are European genera. Holocentris, Myripristis, Priocharax, and Dulus are represented in both hemispheres. Ambassius is an Indian fresh-water genus. The typical forms of Pinguipes, Fistularia, and Pogonias are American. Beryx, Trachichthys, Helotes, Potamia, and Chiroptera are Australian.
IGNIS FATUUS, a meteor resembling a flame, which floats in the atmosphere at a few feet above the surface of the ground. It is generally observed by night, either stationary or in motion, over marshes or burial grounds; but in the "Philosophical Transactions," for 1694, there is an account of some ricks of hay being burnt at Dolgelly, in the preceding year, by a vapour like a weak blue flame which came from the sea: Derham (Phil. Trans. 1729) relates that he observed about a decayed thistle a flame in motion, which receded from him as he advanced towards it; and Beccaria states that he saw a similar effect near Genoa, from some stones near a river: this philosopher observes that such meteors are most usually witnessed during a fall of rain or snow; he adds that they often appear on clayey soils, and that they have been observed in the vicinity of shrubs and bushes. (Stöhr Merkur, 1763) mentions that he saw at Zellerfeld a meteor which at first approached him and afterwards receded from him to a distance of 300 paces; he adds that it then disappeared, and at the end of half an hour it again became visible.

Ocasionally such meteors have been observed to follow or advance towards a spectator; but in general they appear to recede on being approached, and it has happened that from their resemblance to the flame of a distant lamp, they have led the unwary traveller into dangerous swamps. Little confidence can be placed in the descriptions given of them, as few persons have been fortunate enough to examine them with due attention; and commonly they have been observed under the influence of an ill regulated imagination rather than a philosophical spirit.

A plausible hypothesis which has been proposed in order to account for this phenomenon is that a phosphoretted or a carburetted hydrogen gas, produced by the decomposition of animal or vegetable substances, rises from the ground or from stagnant water, either small in that part of the atmosphere that is nearest to the earth, or in great abundance and then becomes a train or a horizontal column of vapour of variable dimensions: such gas may take fire by electricity or spontaneously, at a spot where the atmosphere is hot, or where the ground is suddenly heated by a flame communicating itself successively to other parts of a line or column, the latter being in a state of inflation from the agitation of the atmosphere, will give rise to the appearance...
at a motion from place to place. The brightness of the matter will change with the varying quantity or purity of the gas; and its temporary disappearance may be caused by the quantity being in some places too small to render the flame visible. Spontaneous ignition is well known to take place occasionally in a mass of vegetable and animal substances while undergoing decomposition, in consequence of the inflammable matter coming in contact with common air or with oxidising agents.

ILFORD. There are two places of this name in Essex, both in the hundred of Bexneet. Great Ilford is a village included for civil purposes in the ward and former chapel of Ilford in the parish of Barking; it forms a respectable settlement on the road from London to Chingford and Colchester, about 85 miles from the General Post Office. It is on the left or east bank of the river Roding, which is here crossed by a bridge. The river is navigable for small craft up to the bridge, under the name of Barking creek. The name Ilford is derived from Morant from the ill ford that must have been here before the causeway and bridge were erected; and by Mrs. Osborne from a ford at the hill, written Hyleford.' Great Ilford has a new church, erected in 1831 by the aid of a grant from the commissioners for building new churches. The chapel was then constituted a distinct parish. The church is in the 'gothic style, with tower and spire,' and is capable of accommodating about 850 persons. Mr. Wright describes it as a handsome building. There is also a small chapel (St. Mary's) a half-mile distant from the church (Trinity Chapel) has been erected at Barking-side in the parish of Ilford, capable of accommodating 465 persons, to which a chapel was added by the generosity of the Rev. Thomas Norton, vicar of the church. Also the same parish. The church is in the Anglo-Norman style, with a small belfry. There are also in the village two dissenting chapels. Ilford ward contained in 1831, 725 houses, namely, 658 inhabited by 701 families, 4 houses building, 1 and 21 uninhabited; with a population of 3512: in 1841 it contained 771 houses, namely, 721 inhabited, 32 uninhabited, and 18 building; with a population of 3742, showing an increase in ten years of 231. The whole of the great Ilford is best known by the clear yearly value of 400l., in the rural deanery of Barking, the archdeaconry of Essex, and the diocese of London. The educational returns for 1833 do not distinguish the yard of Great Ilford from the other divisions of Barking parish.

Little Ilford is a parish separated from that of Barking by the river Roding. The parish has an area of 750 acres, and contained in 1831, 22 houses inhabited by 23 families, and 1 house building; the population was 115: in 1841 it contained 23 inhabited houses, with a population of 189; of whom 30 were prisoners or officers in Ilford goal, which is a house of correction for the county, erected in 1831. The church is dedicated to St. Peter, Linwall, and is surrounded by a green belt of trees, and is approached by a lane surrounded by the old town of Ilford, and by a new one leading to the church. The living is a rectory of the clear yearly value of 400l., with a glebe house in the same ecclesiastical divisions as Great Ilford. There was a school for boys and girls opened in 1833, but children were taught to read every Sunday morning and afternoon in the church. (Morton, History of Essex; Mrs. Osbourne, History of Essex; Wright, History of Essex; Reports of Commissioners for Building New Churches; Population Returns, and other Parliamentary Papers.)

ILICINE. [Acroclinia, P. C. S. J.] ILICICLE. [Frangula, P. C. S. J.] ILICICLE BRUM. a genus of plants of the natural order Illiciaceae. It has five scales slightly coherent at the base, which disintegrate at the back. Petals absent or five subulate inserted with the five stamens on a perigynous ring; a one-celled one-seeded furrowed capsule bursting along the sutures. The only species is a small trailing shrub with opposite, oval, sharp-pointed leaves at the base.

t. verticillatum. Whorled Rbush-grass. It has a trailing glabrous stem, roundish leaves, verticillate whorled white minute flowers. It is found in bogs and marshy places, chiefly in the county of Devonshire. The seeds of this shrub should be planted in a moist situation, if allowed to grow themselves, will spring up regularly every season. It is worth cultivation on account of the delicacy and beauty of its blossoms.

ILMEN, LAKE. [Russia, P. C. J.] IMOLA, INNOCENZIO DA, a pupil of Francis, and a distinguished painter, of the early half of the sixteenth century. His family name was Francucci; he was born in the later part of the fifteenth century, at Imola, whence his surname, but he lived and worked in Florence. He painted from 1506 until 1549: Vasari says he died aged fifty-six, but this is apparently an error, or he must have commenced to paint when only thirteen years of age. However, about 1506 he was placed with Francis, and, according to Manucci, also with Albertinelli at Florence. In 1517 he produced what is now considered his masterpiece. It is a large picture, now in the palazzo Cusani at Bologna, but formerly over the great altar of San Michele in Bosco, Bologna. He painted the left part, the Archangel Michael vanquishing Satan, Saints Peter and Benedict at the sides, and above in the clouds the Madonna and Child surrounded by angels; the whole is treated much in the second manner of Raphael. It has been engraved by A. Marchi for the 'Pinacoteca di Bologna.' There is also a very superior work by him in the cathedral of Faenza. Da Imola's style is termed by Lanzi Raffaellismo, and it appears that several of his works have passed for the works of Raphael, that is, for works of his second style. He was also a good fresco painter.

(Vasari, Le Vite, iii. 188, et seq.; Lanzi, Storia Pittorica, &c.; Giordani, Pinacoteca di Bologna.)

IMPEACHMENT. [Parliament, P. C. J., 279.] IMPEFATORVIA (so named from its supposed imperial virtues) is a genus of plants belonging to the natural order Umbellifereae. It has no caules; obovate petals contracted into an infixed segment. The fruit flattened at the back with a dilated flat border. The species are glabrous, with a few spreading hairs. It is assigned to the subfamily. The umbilics are large and compound, and the flowers white.

1. Ostruthium has a tuberos firm and somewhat creeping root of an aromatic and scented nature. The lower leaves bitter-tasting, the upper smell of the herb; and, of a white or pale flesh-coloured hue. It is a native of Europe and Newfoundland in damp meadows and woods. This species is the Masterwort of old English herbalists, and is a species of poisoning and an antidoate against poisons, a diuretic, and sudorific; and Lervengo affirms that an infusion of it in wine has curedaguehas which have resisted quinine. When chewed, it excites a copious flow of saliva, and acts as an agreeable stimulant to the gums. It is recommended in cases of rheumatic toothache, and is cultivated in many places for the London market.

2. angustifolia, the Narrow-leaved Masterwort, has alternate leaves, oblong lobate attenuated at the base and deeply serrated. It is a native of the Alps and Piedmont. The blossoms appear in June and July, and are of a white colour. This species of the genus is so easily cultivated, and may be propagated very easily, and remains a nomenclature of Botany.)

IMPRESSMENT. [Seamen, P. C. S.] IMPRESSION, FALSE. [FALSE IMPRESSION, P. C. S.]

INCENDIARY. [Arson, P. C. S.; Law, Criminal, P. C. S.] INCENT. During the Protectorate in the year 1650, incest and adultery were made capital offences, but at the Restoration this law was not confirmed. Incest in England is now only punishable by the ecclesiastical courts, according to the rules of the canon law. This law also determines what kind of sexual connection is incest. Incest may be committed either by married persons or persons unmarried. If adultery is committed, it may also be incest; and if fornication is committed, it may also be incest. The notion of incest is founded upon the degree of consanguinity or affinity between the parties who have had the sexual connection.

The term Incest is from the Roman term Innocentum, which is the same as Non Castro legem. This law also determines what kind of sexual connection is incest. Incest may be committed either by married persons or persons unmarried. If adultery is committed, it may also be incest; and if fornication is committed, it may also be incest. The notion of incest is founded upon the degree of consanguinity or affinity between the parties who have had the sexual connection.

The term Incendium is from the Roman term Incestum, which is the same as Non Castro legem. This law also determines what kind of sexual connection is incest. Incest may be committed either by married persons or persons unmarried. If adultery is committed, it may also be incest; and if fornication is committed, it may also be incest. The notion of incest is founded upon the degree of consanguinity or affinity between the parties who have had the sexual connection.

The term Incendium is from the Roman term Incestum, which is the same as Non Castro legem. This law also determines what kind of sexual connection is incest. Incest may be committed either by married persons or persons unmarried. If adultery is committed, it may also be incest; and if fornication is committed, it may also be incest. The notion of incest is founded upon the degree of consanguinity or affinity between the parties who have had the sexual connection.
The Roman notion of Incestum was not confined to the case of blood relationship. Persons who stood in the relation of parents by adoption could not contract a marriage even after the adopted child was emancipated. The Romans do not appear to have had any direct legislation on this subject till the Imperial period, and the rules of law that were afterwards adopted probably date from the same time. The Lex Julia which was enacted in the time of Augustus treated of incest only indirectly, and so far as it concerned the object of that law, which was the punishment of adultery.

In some cases of incest at Rome, there was capital punishment. (Dion Cassius, vii. c. 22; Tacitus, Annal., vi. 19.)

The subject of the Roman Incestum is treated copiously by Reti, Criminales rerum, and with a reference to the numerous authorities.

INCH OF CANDLE. [Auct. P. C.]

INCHBald, Mrs. Elizabeth, whose maiden name was Simpson, was the daughter of a Suffolk farmer residing near Bury St. Edmunds. She was born in 1753. Prone to romantic notions, and losing her father in youth, she ran away at the age of sixteen to seek her fortune, and endeavoured to procure an engagement as an actress in London. After several adventures, she obtained a place in a country theatre, and soon married Mr. Inchbald, a respectable actor, much older than herself, with whom she found much regard and comfort. Mr. and Mrs. Inchbald performed for four seasons in Edinburgh, and, after an engagement at York, went to France for a time. In 1779 Mr. Inchbald died at Le Havre, leaving her a widow and his plays, which had been published, come upon her. She went to Russia, and afterwards to Batavia, where she lives on the income which she had received from her plays, which, in the beginning of the 19th century, were copiously and extensively produced. She is considered as one of the greatest actresses of her time, and is the great dramatic genius not of a very high class; but several of her comedies had much success, and one or two of them still keep their place on the stage. They gained her for the means not only of supporting herself with honourable dignity, but of making a handsome allowance to an invalid sister, and of saving a considerable sum. Her melodramatic comedy of 'Such Things Are' gained her more than four hundred pounds; as much was produced by 'Wives as Were and Maidens as They Are,' and for 'Every One has His Fault,' the money produced by her plays, she received seven hundred pounds. She edited, with biographical and critical remarks, 'The British Theatre,' a collection of acting plays, 26 vols., 1806-1810; 'The Modern Theatre,' 6 vols., 1809-1810; 'A collection of Farces,' 7 vols. Mr. Inchbald was a great genious, and his literary talents are best exhibited by her two novels, 'A Simple Story,' first published in 1791, and 'Nature and Art.' In the latter she became extremely popular, and deservedly so, and have been reprinted in our time in collections of standard novels. She died on the 1st of August, 1821, in a boarding-house at Kensington, leaving nearly 6000l. in legacies to her relations and friends, to the Roman Catholic poor, to the Covent-Garden Thespalic Fund, and small sums to her laundress and hairdresser, 'provided they should inquire of her executors concerning her decease.' She had written an account of ancient usages in the two last vols. of her 'Modern Theatre' which were worth four hundred pounds for it; and, in obedience to her will, it was destroyed after her death. But her journal, kept regularly for many years, was preserved; and it from her letters were written Mr. Johnson's Miscellany. She was a great lover of the theatre, and when she went abroad on the first visit to Russia, she always took her theatrical packets with her.
In gives and would be the right of grazing sheep at all belongs to a man called a flock-master, and he has the power, during certain months of the year, of turning his own sheep and the cattle of others upon the parish; or, according to particular circumstances, his right is limited and restricted to turning sheep upon a certain portion of it, with a view to giving parties an opportunity of putting in a wheat crop. In those parishes where there is a flock-master who has a right of depasturing his sheep during a certain portion of the year over all the land of the parish, it is clear that no one can sow any wheat without having made a bargain with him for shutting up his own particular fields, or some proportion of them.

There is a very large extent of wood-land in this kingdom that is commonable, strange to say, where certain individuals have a right during the whole year to turn on stock, the owner of the wood having no means of preserving his property except by shutting out other commoners' stock by custom for some two or three years after felling. There is that right, as also the right of the so-called common arable, which is a very great inconvenience in various parts of the country, where parties have the right of cutting house-bote, and plough-bote, and fire-bote, and so on in woods belonging, quivi wood, to another party. There is a great deal of land such as that which is occupied exclusively by the commonable, these commonable lands, but these are the most prominent and remarkable of them.

Under such a system as this, it is obvious that those common fields must be re-introduced. The intermixed lands cannot be treated according to the improved rules of good husbandry. It is stated that the simple re-distribution of intermixed lands, now held in parcels so inconvenient in form and size as to be impossible to drain them, would in a very few years clear up the entire waste of the lands from 15s. or 17s. an acre to 30s.

It is the opinion of witnesses examined before the parliamentary committee of 1844, on Commons' Inclosures, that judicious inclosure would make a large portion of common lands much more productive. At present open arable lands are so intermixed that beneficial drainage is nearly impossible. One witness says: 'I have had occasion to go over two small properties, about 150 acres each; one I found in 301 different pieces, and the other in a little more than a hundred. I mention this to show how the lands are frequently intermixed; the water is often detained at much expense; and it is impossible to drain them on the present improved mode of drainage, inasmuch as other parties are occupying the furrow by which the water should pass off.' In the Midlands counties, it is stated, the common is divided into two crops and a fallow, and every third year the flocks run over the whole field. The same witness considers that a fourth of all the open arable land is at present totally unproductive. In cases where common arable fields have been sub-divided and allotted, 'the great improvement is, that in the first place every man has his allotment, and he deals with it as he pleases; he drains it, and crops it upon a proper course of cropping; he puts it in seed and keeps sheep upon it: he grows turnips and clover, or whatever he thinks proper.' The same witness is of opinion that the average improvement in the cultivation of common lands now has been, and inclosure is likely to be less than 25 per cent. Indeed the evidence that was produced before the committee establishes to a degree beyond what otherwise would be credible, the immense inconvenience and loss of time occasioned by the system of intermixed lands, and their being also subject to commonage.

As to Common Rights, that is, rights of pasture and so forth on commons or waste lands, they are described generally under the term of, for, P. C. Any intermixed parcel of common and waste lands, they also require an improved management. It is stated that commons are generally overstocked, partly in consequence of persons turning out more stock than they have a right to do, and partly by persons putting their stock on the common who have no right. In consequence of commons being overstocked, they are profitable to nobody; and a rule for regulating the quantity of stock would therefore be beneficial to persons who are entitled to this right of commons.

Violent disputes also frequently arise in consequence of the rights of parties to commonage not being well defined. It is the opinion of competent judges that very great advantage would result from stining those parts of commons that are not worth inclosure, and that it would be highly desirable to inclose portions of a common for the purpose of cultivation, and to allot such portions of it, whilst it would be impossible to do more than to limit other portions of it. A state of inclosure is the right of the wild animal, or for a certain number of animals, according to age, size, and capability of eating. 'The commons in fact are not now subject to the laws of the lands or parishes, they cannot be brought into practical operation: and besides this there are many commons in gross. [Commons, Rights of, P. C.] Inclosures of land have now been going on for many years. It is stated that since 1800 about 2000 inclosures acts have passed; and prior to that time about 1600 or 1700. It seems doubtful from the evidence whether the 1600 or 1700 comprehend all inclosure acts passed before 1800. These inclosure acts (with the exceptions which will presently be mentioned) are private acts, and the expense of obtaining them and the trouble attendant on the carrying their provisions into effect have often prevented the inclosure of commons.

In 1836 an act (6 & 7 Wm. IV. e. 116) was passed for facilitating the inclosure of open and arable fields in England and Wales. The preamble to the act is as follows:—'Whereas there are in many parishes, townships, and places in England and Wales, many of the common lands and fields, the lands and the lands of the several proprietors of the same are frequently very much intermixed and dispersed, and it would tend to the improved cultivation and increase of the produce of the common lands and lands occupied by the proprietors of the same, and to make a large number of lands advantageous to the proprietors thereof, and persons interested therein, if they were enabled by a general law to divide and inclose the same,' &c. Inclosures have been made under the provisions of this act, in which the powers which it gives are limited, for the 'act applies solely to lands held in severity during some proportion of the year, with this exception, that slips and balks intervening between the cultivated lands may be inclosed,' and can only obtain one by lapsed of time. The chief motive to this dealing with commons appears to have been, that they thus got the inclosure done cheaper than by applying to parliament for a private act.

In 1844 an act of Commons was appointed to inquire into the expediency of facilitating the inclosure and improvement of commons and lands held in common, the exchange of lands, and the division of intermixed lands. Under this act, the committee were to inquire, in the first instance, into the state of many commons, and to report their opinion to the House. The committee made their report in favour of a general inclosure act, after receiving a large amount of evidence from persons who are well acquainted with the subject. The extract that has been given in this article are from the printed evidence that was taken before the select committee.

In pursuance of the recommendation of the committee, an act of parliament was passed in 1845 (8 & 9 Vict. c. 115), the object of which is thus stated in the preamble:—'Whereas it is expedient to facilitate the inclosure and improvement of common lands and lands held in inclosure or divided into parcels, and the partial or entire exchange of such lands, commonly called arable commons, or new fields, and to obviate the detrimental effects of such improvements, and to encourage and facilitate such exchanges and divisions of lands, between the proprietors of the same, and to report their opinion to the House.' The committee made their report in favour of a general inclosure act, after receiving a large amount of evidence from persons who are well acquainted with the subject.

It is not within the scope of this article to attempt to give any account of the provisions contained in the 160 sections of this act; but a few provisions will be noticed that are important, and may be of interest to some. The 11th section contains a comprehensive description of lands which may be inclosed under the act; but the New Forest and the Forest of Dean are entirely excepted. The 14th section provides that no lands situated within forests...
miles of the city of London, or within certain distances of other towns, which distances vary according to the population, shall be subject to be inclosed under the provisions of this act without the previous authority of parliament in each particular case, excepting those parts of India which are town-greens or village-greens, and contains other regulations as to them. The 30th section provides that an allotment for the purposes of exercise and recreation for the inhabitants of a neighbour-
hood may be required by the common-pers under the act, as one of the terms and conditions of an inclosure of such lands as are mentioned in section 30.

The 108th section makes regulations as to the allotment which, upon the application of the labouring poor, and section 109 the allotment wardens (appointed by section 108) shall from time to time let the allotments under their management in gardens not exceeding a quarter of an acre each, to such poor inhabitants of the parish for one year, or from year to year, at such rents, payable at such times and on such terms and conditions not consistent with the provisions of this act, as they shall think fit.

Section 112 provides for the application of the rents of allotments; the residue of which, if any, after the payments mentioned in this section have been defrayed, is to be paid to the overseers of the poor in aid of the poor rates of the parish.

Sections (147, 148) provide for the exchanges of lands not subject to be included under this act, or subject to be inclosed, as the case may be; no proceedings for an inclosure shall be pending, and for the division of improved lands under the same circumstances.

Under section 152 the commissioners are empowered to revoke any inclosure or allotment so as to restore a man inhabiting a part of it to the possession thereof, to be in the hands of the select committee; and there can be no doubt that agriculture will be greatly improved, the productiveness of the land increased, and employment given to the poor by this judicious and important act of legislation.

The 'London Gazette' of August 22nd, 1845, notified the appointment by the Secretary of State of two Commissioners of Inclosures.

(Report from the Select Committee on Common Inclosure, together with the Minutes of Evidence and Index. The Report is accompanied with maps which explain various parts of the evidence. A complete digest of these Minutes of Evidence would form a very instructive article on the state of agriculture in England at that period, and especially as regards the work of the Wise men here above mentioned is of necessity very incomplete. The witnesses appear to agree in the main, but there are some differences of opinion, which a reader of the Minutes will not fail to see.)

INCORPORATION, TAXATION, INCUBATION, ARTIFICIAL. [Poultry, P. C., pp. 477, 478.]

INDUCEMENT. [Barnes, P. C.]

INDIA. It was intended to give, under this head, a general view of all the territories of Hindustan, their areas, population, revenue, by whom held, names of the great divisions, and other details political and statistical. It will be convenient, for the sake of bringing down the information to the latest date, to postpone the article by referring it to Taxonomies of India, P. C. S.

INDIAN LAW IN THE MININSON. The act of the 3 & 4 Wm. IV. c. 85, by which the privileges of the East India Company are regulated, provides for the establishment of a Law Commission in India. The 58th section rectifies that it is expedient, subject to such special arrangement as local circumstancies may require, that a general system of judicial establishments and police, to which all persons whatever, as well Europeans as natives, may be subject, should be established in the East Indies, and that such laws as may be applicable in common to all classes of the inhabitants, having a due regard to the rights, feelings, and peculiar usages of the people, should be enacted, and that the laws, and customs having the force of law in the East Indies, should not be altered.

For this purpose the appointment of a commission of five members was authorized, to be called 'The Indian Law Commissioners.' They were to report from time to time, and to suggest such alterations as they should consider could be beneficially made in the courts of justice and police establishments, in the forms of judicial procedure and laws, due regard being had to the distinction of castes, difference of religion, and manners and opinions prevailing among different races, and in different parts of India and Chartered Companies. India is subject to the same system of laws as the native population, the influence of the opinion of the former in the administration of justice will prevent abuses to which the latter might be exposed without the benefit of the complaints in this country. Mr. T. B. Macaulay was the chief member of the first commission. The report of a penal code was presented to the Governor-General on the 15th of June, 1836. The groundwork of it is not taken from any system of law in force in India, though compared with and corrected by the practices of the country. The principles of the British law, the French code, and the code drawn up by Mr. Living-

ISTATE FOR THE State of Louisiana, are the foundations of it. Most of the articles which it contains are accompanied with illustrations to facilitate the application of the law, and it is thus a statute-book and a collection of decided cases. This report was signed by Messrs. Macaulay, J. Ramsay, M. Macleod, G. W. Anderson, and F. Millet. The progress of the present commissioners in dealing with the general law of India has not been published. (Penal Code, Parliamentary Paper, 1836, No. 132.)

INDUCEMENT. [Laxading, P. C.]

INFAMY (from the Roman Infamia) in English law is not easily defined. There are certain offences which are commonly considered such that conviction and judgment for such offences renders a man infamous and incompetent to be a witness. The absurdity of the punishment, or refusal of the judgment, of a man convicted for an act of which he can only be guilty is a very curious part of the system of law. This is the effect of the act, and without the act, a man convicted of a felony shall have undergone the legal punishment for it, he shall be the same as a pardon under the Great Seal; and (§ 4) no misdemeanor, except perjury or subornation of perjury, shall render a man an incompetent witness after he has undergone his punishment. The 6 & 7 Vict. c. 85, enacts, that no man shall be excluded from giving evidence, though he may have been convicted of a felony, when not a witness against himself.

Certain offences enumerated in the 7 & 8 Geo. IV. c. 29, § 9, are infamous crimes, with reference to the provisions of that act. Though infamy does not disqualify a man from being a witness, it may be urged as an argument against his credibility.

The only satisfactory definition of infamy would be a per-

manent legal incapacity to which a man is subject in conse-
quence of a conviction and judgment for an offence, and which is not removed by suffering the punishment for the offence. By 2 Geo. II. c. 24, § 6, persons who are legally convicted of perjury or subornation of perjury, or of taking and asking any bribe, are incapable of being members of parliament. They are therefore in-

famous: they labour under infamy: and have lost part of their political rights.

The Roman term Infamia is the origin of our term infamy. Infamia followed in some cases upon condemnation for certain offences in a judicium publicum; and in other cases it was a direct consequence of an act, as shown in the following example. F. C. S.

Among the cases in which Infamia followed upon condemnation, were, insolvency, when a man's goods were taken possession of by his creditors in legal form and sold; the actio furti, and vi honorum raptorum; actio seditiose; actio raptorum; actio tutelae, &c. In all cases a judicial sentence, or something analogous to it, was necessary, before Infamia could attach to a person. Among the cases in which Infamia followed as an immediate consequence of sentence, F. C. S. notorious are the following: the case of a woman caught in adultery, of a man being at the same time in a relation of a double marriage, of prostitution in the case of a woman, or when a man or woman gained a living by aiding in prostitu-

tion. The consequence of Infamia was incapacity to obtain the honours of the state, and probably the loss of the suffrage also; and it was perpetual. The Infamia was still a citizen (citius), but he had lost his political rights. The infamous man was also under some disabilities as to his so-called private rights. He was limited by the Prout's edict in his capacity to postulate (this is, take the internal measures for founding or defining laws, or advancing public business). In this respect the appointment of a commissioner of five members was authorized, to be called 'The Indian Law Commissioners.' They were to report from time to time, and to suggest such alterations as they should consider could be beneficially made in the courts of justice and police establishments, in the forms of judicial procedure and laws, due regard being had to the distinction of castes, difference of religion, and manners and opinions prevailing among different races, and in different parts of India and Chartered Companies.
INFANT \( \text{HEIR.} \) \( \text{[HEIR, P. C.]} \) INFANT TRUSTEE. \( \text{[TRUSTEE, P. C.]} \)

INFANT, in the law of Scotland, from the same origin as the English term efferent, expresses the ceremony by which a person succeeding to another by descent, settlement, or contract, is invested in any heritable or real property. Down to the year 1845 this ceremony was as pure a feudal usage as it ever had been in the days when the almost universal inability to write suggested symboilical modes of characterising events. Suppose a very ordinary case—that a person purchases a piece of ground from one who holds it of a superior. According to the system of sub-infeudation preserved in Scotland, he may either be put in the seller's place and hold of the same superior, or he may hold a sub-feud under the seller. Whoever is to be the superior, the title deed contains an authority from him to invest the vassal. Until the late change, a number of persons had to proceed to the ground, consisting generally of the attorney who prepared the titles, and his clerks, who had the following parts to act. One was the bailiff of the superior, and a commission authorizing him to act in that capacity was read over. Another party acted as the procurator, or appointee of the tenant in possession. The bailiff lifted some fragments of earth and stone from the soil and handed them to the procurator, as symbols by which, according to the authority given to him, he made over possession of the tenant to the other party. The receipt of the symbols then placed a coin of the realm in the hands of another party, who must have had a notary public—this being the form in which a protest is taken in the hands of a notary in Scotland. Two other symbols were written, the procurator, with the authority on which it proceeded, was narrated in a deed called an instrument of sasine, in which the notary publicly attested the transaction. The preservation of this cumbersome ceremony down to so late a period was owing to its connection with the admirable system of registration which has kept the commerce in real property in Scotland on so clear and secure a position. The whole ceremony went for nothing unless the instrument narrating it was recorded in the Register of Sasines within sixty days after the ceremony. The registration was and is the criterion of preference. If land should be sold or mortgaged to any number of different people, the person whose sasine is first registered has the absolute title, and all questions as to the fairness of the transaction, are pecuniary questions to be settled apart from the title to the lands. The cumbersome ceremony mentioned above was rendered no longer necessary by the 8 and 9 Viet. c. 55, passed 21st of July, 1846, and called 'An Act to simplify the form and diminish the expense of obtaining sasine in heritable property in Scotland.' It simply provides that 'it shall not be necessary to proceed to the expenses of a title deed when the same is to be given by way of sasine thenceforth; but sasine shall be effectually given therein and sasine obtained, by producing to a notary-public the warrant of sasine and relative writings, as now in use in the laws and usages of Scotland, containing the instrument recording *. * * an instrument of sasine, setting forth that sasine had been given in the said lands, and subscribed by the said notary-public and witnesses.' There has been little opportunity to observe the working of this act, but it is evident that it will materially reduce the expense of transferring interests in landed property in Scotland. A costly ceremony and a long deed, essential to the durability of every title of a new holder, are abolished by it. The act at the same time contains some methods of remedying mistakes and omissions which under the old law were fatal flaws.

INFORMER. An informer is a man who lays an information or prosecutes any person in the King's courts for some offence against the law or a penal statute. Such a person is generally called a common informer, because he makes a business of laying informations for the purpose of obtaining his share of the penalty. [\text{INFORMATION, P. C.}] Persons are induced to take the trouble of discovering offences, for which a pecuniary penalty is inflicted on the offender, by the promise of the reward; and if the penalty is imposed for the public benefit, we may conclude that the maker does the public a service. But still the business of a common informer is looked on with dislike, and he who follows it is generally despised; and perhaps the character of common informer is one of those that are not dangerous to the public. They stand in a like situation to the common hangman. This dislike of informers, simply as such, is one of the ancient prejudices, who have their benefactor. The real foundation of the dislike however is, that they form a just judgment of things is, not the act of information, but the devices, tricks, and meanesses to which a man must resort when he wishes to have his information must be founded. It is the same principle which leads us to condemn a man for making certain statements in public, not because of the statements, but because of the means by which he may have obtained his knowledge. What a penalty is too heavy, or when the law that imposes generally disliked by the people for any reason, good or but the popular dislike finds a definite object in the informer wha causes effect to the common sense of the community. The law is overlooked, because the legislature is a number of persons. The informer is one, and his agency is seen and felt.

In absolute governments there are spies and political informers, who are the tools of a government which has no rule but its own pleasure. Some people have been dull enough to confound all informers in one class; not seeing that there is a difference between an informer who helps to give effect to the law, and an informer who helps to tyrannical govern-
of difference appears in their siliceous shields to authorize conclusions more or less positive as to the marine or fresh-water origin of infusorial deposits, which contain identical or analogous forms belonging to earlier periods. Thus the rich deposits of Richmond in Virginia appear to have been formed beneath the sea; the famous deposits of Bohemia, Berlin, and Santa Flora contain admixtures of marine and fresh-water tribes; while those of Bami, in the county of Down, and Gainsborough and Bridlington, contain a more considerable proportion of fresh-water species.

Infusoria of marine or estuary origin have been found in a fossil state very extensively in Europe, Asia, Africa, and America. Ehrenberg has described many species from Greece (Zante and Egina), Italy (Callatisnetta and Cattarles), and Africa (Oman), which occur in calcareous marls, referred by Ehrenberg to the age of the true chalk deposits. These deposits are very extensive in Africa, occupying the whole coast of Oman and large tracts in Egypt and Arabia. Portions of this tract have, however, been described by M. Roset as tertiary. In the undoubted white chalk of Denmark (Rügen), of France (Meudon), of England (Gravesend and Brighton), infusoria also occur, but less abundantly. North America has yielded a great variety of marine or partly marine infusoria, especially at Richmond and Petersburg in Virginia, at West Point, in Connecticut, Rhode Island, Massachusetts, and Maine. Brazil has also yielded similar deposits.

Infusoria partly of marine and partly of fresh-water origin have become familiar to us in the Polierschief (polishing slate) of Bilin and Planitz in Bohemia, and of the Habichtswald near Cassel, the Bergmehl of Santa Flora in Tuscany, the white marls in the peat of Franzenbad near Egra in Bohemia, the peat deposits of Gainsborough in Lincolnshire, and at the base of the Mourne Mountains in Ireland. We find them to occur also in considerable plenty, but in limited distribution, in the lavas, in the deposits of the East coast of Yorkshire. The Isle of France is added to these localities by Ehrenberg, and New Zealand by Mantell, all the occurrences belonging to supra-tertiary areas.

Infusorial remains are very unequally congregated. The siliceous marl (Kieselguhr) of Franzenbad consists mainly of Navicula viridis (fig. 6) (now recent); that of the Isle of France, of Bacillaria vulgaris (fig. 7); that of San Flora, of Synedra capitis (fig. 9); while that of Bilin is composed chiefly of Gallionella distans (fig. 8) almost exclusively. (Ehrenberg.)

Infusoria are mentioned in the moya (volcanic mud) of Mexico, and in the edible clay of the Amazons River, by Ehrenberg; in the rock salt and the marl which accompany it at Cordoba in Spain, by Marcel de Serres; they are assumed by Ehrenberg to enter largely into the composition of flint, which indeed readily shows Xanthidia and Pyxidincula. The bog-iron ore (Raseneisenstein) common near Berlin is composed chiefly of Gallionella ferruginea. A kind of semipolish lying in nodules in the Polierschief of Bilin is composed of the same siliceous relicia (Gallionelle), as the true polishing slate, but they are cemented together and filled by a calcareous paste. With these Ehrenberg finds spicula of sponges. The precious porphyry opal of Kaschau, and the serpentine opal of Kosanite in Silesia, has appeared to Ehrenberg of analogous composition. The following tabular view given by Ehrenberg of some of these facts will be useful:

1. Bergmehl
2. Kieselguhr
3. Polierschang
4. Sassgheifer
5. Semipolish of Polierschief

The above consist entirely or partly of the shells of Shield-Infusoria.

6. Semipolish of the Dolerite
7. Precious opal of the porphory
8. Flint of the chalk
9. Gilberde (yellow earth)
10. Raseneisenstein
11. Certain kinds of Steinmark, investing the opal of Kaschau

The above are probably of the same nature.

As examples of undoubted marine infusorial fossils we give below figures of some of the forms most frequent in a white deposit from Richmond.

And for comparison the following outlines of mixed marine and fresh-water species common in the Polierschef of Bilin and the Peat and Kieselguhr of Franzenbad, Egra, San Flora, &c.

These are tertiary forms, and below is a specimen of a group referred to the recent genus Xanthidia, and frequent in the flint nodules which occur in chalk.

11. Xanthidia renocau.

List of species of infusoria from the Kieselguhr of Franzenbad—Navicula viridis (plentiful), N. gibba, N. fulva, N. librite, Gomphonema paradoxum, Gomphonema olivatum (fresh water species now living near Berlin); N. viridula, N. striata (now living in the sea, the second also lives in the Carlsbad water); Gallionella varia.

Species of infusoria in the peat bog of Franzenbad—Eunotia granulata (plentiful), Navicula viridis (rare), Bacillaria vulgaris, Cocconeis umhultana, Gomphonema paradoxum.
Species which occur in the Kiel Canal of the Isle of France—Basillaria vulgaris? (plentiful), B. major, Navicula fulta? N. gibba, N. bifrons (living near Berlin).

In the Bergemehl of Santa Fiora—
Syndera capitata (plentiful); with this are S. ulna (living both in fresh water and sea); Navicula inequilata, N. capitata, N. viridula, N. gibba (fresh water species); N. viridula (living in Baltic); Eunotia granulata, Navicula foliis (distinct); Cocconeis unisulcata (marine); Gomphomena paradoxica, G. vacutum, G. acuminatum (living near Berlin); Cocconeis cymbiforme (fresh water); Gaillonella italicca; Spicula of spinogon or spongiella.

In the Po1 of the River of Bilo—
Podosphaera navis (plentiful), Galionella distans, Navicula scalarum, Bacillaria vulgaris? (probably all marine). In the Leli Tripoli—
Galionella distans (plentiful), Podosphaera nanata, Basillaria vulgaris? (probably marine).

At Bann, in the county of Down, Captain Portlock found under peat, Navicula, Bacillaria, Eunotia, with fragments of anchnides and acanthoecysta. (Microscopical Journal, 1841.)

At Gainsborough, Mr. Binney found under peat, abundance of Gaillonella. At Bridlington, we have observed in white and brown marls, Eunotia serra? Bacillaria vulgaris, Navicula inequilata, N. viridula, N. phaeocerata, Cocconeis laneculata, a new and beautiful Campildocius (C. zonale), etc.

The North American localities have yielded to Bailey and Ehrenberg a large catalogue of infusoria. Ehrenberg enumerates:—
Amphipora—one species.
Cocconeis—two species.
Eunotia—seven species.
Fragilaria—three species.
Gomphomena—four species.
Himmites—four species.
Navicula—fourteen species.
Staurastrum—two species.
Tabellaria—three species.

With these three forms of spongod spicula, and two species of Thyphoclum.

Flora are mostly derived from beds lying under peat.—
The Richmond earth (of micocene date) yields—
Cocconeis radiata and other species (fig. 3).
Achnococys supercilious and others (fig. 3).
Navicula, several species.
Gaillonella.
Dietrichia fuscata (fig. 1).

In the chalk marls of Oman, Sicily, Greece, etc. occur many living forms, Actinothamn—ten species.
Amphididium—two species.
Biddulphi—one species.
Cocconeis—one species.
Cocconeis—seven species.
Dietrichia—four species.
Eunotia—two species.
Gaillonella—two species.
Griammatophora—four species.
Halmocoma—one species.
Navicula—six species.
Sirellia—one species.
Syndra—one species.
Tenella catena—one species.
Triceratium—one species.
In the white chalk and flint of Europe, and also living,—
Fragilaria rhodosa—Gravesend.
striata—Gravesend.
Gaillonella aurichales—Riga.
Peridinium pyrophorum—Gravesend.
Xanthidium furcatum—Gravesend.
hirustum—Gravesend.

Dr. Mantell has been unable to discover Fragilidium in the chalk marls of the Elbe, but he has found it in the chalk of Dover. (Ann. Nat. Hist., Aug. 1845.) Gaillonella aurichales has been regarded as an Oncidiaria; and it appears doubtful whether the so-called Xanthidium of the flints and chalk is really the same species that occur in fresh water.

From the preceding notices we may gather as general facts the occurrence of infusoria remains in the following stratafication:—

Recent Florulitite and other soliments.
Recent deposits of the Lembre period.
Recent Tertiaries.
Eocene Tertiaries.
Chalk deposits.
Oolitic deposits.

The relative abundance of the Infusoria in these several strata, as in the Cretaceous strata, is again observed, as there areTI]e same peculiarities in the Jurassic, and the Cainozoic periods. It is true that Ehrenberg, by assigning to the cretaceous area the calcareous marls of Oran, Sicily, and Greece, gives a picture of the flora of Mesozoic times, and that the upper Cainozoic is a period of infusoria, but the influence of such localities as the Rotaliaceae, Tint allowed, which occur both in the true chalk and in such marls. But on the other hand, remembering the long scale of geological time through which these genera of Polythalamiae extend, and taking into consideration the fact that some species which occur in the chalk of Europe are quoted by Ehrenberg from unquestionably micocene strata in America, we shall hesitate to admit that these truly micocene species are at all causal with the white chalk in which comparatively very few remains of the group occur, and these not of the same species as those which abound in the other deposits.

Another point which the authority of Ehrenberg has not been received without hesitation, is the absolute specific identity of a large proportion of the fossil and recent infusoria. The previous discoveries of geology had prepared an easy admission for the opinion that many of the tertiary forms of infusoria were indistinguishable from living races; such is the fact in regard to all the invertebral races; but with very few, and those not always allowed, exceptions, the secondary strata have been found to contain only extinct forms. It is true to say, the minute Polythalamiae and found many of them similar to living types, and confirmed this influence by independent researches among the infusoria. Supposing these opinions of the Latin microscopist to be confirmed by future inquirers, we shall find that they involve no innovation of the relations of zoological forms to geological time, which have been established from examinations of the other classes of the animal kingdom. The systems of life in each successive system of strata are not separate and distinct creations, but successive terms of a creative series; each of these terms is compound, and to (spoke exactly), its constituent quantities (such as classes, orders, families, genera, or species) have their own coefficients and exponents; that is to say, have their own times of duration, their own periods of abundance, their own peculiar relations to earlier and later organizations.

A rule drawn from Fishes cannot be applied to Moluscas, a law based on Crustacea cannot be received for Micronoria, without living examination; and Paleontology is full of examples of the unequal periods of duration which belong to the different organizations, and the unequal degree of development, and unequal geographical diffusion, which characterize these organizations at the same epochs and during the same periods.

Admitting the authority of Ehrenberg's determination of species, we find another curious and unexpected result—the frequent, if not general, admixture of marine and fresh-water species—in the comparatively level regions of Europe. In the plains of North Germany, round the Bohemian and Harz mountains, in Tuscany, and Yorkshire, we find this admixture of supposed marine and supposed fresh-water races, in the supertertiary deposits. Is it to be explained by supposing those deposits to have been formed while the relative level of land and sea was different from what it is at present, and the sea was not in the place of deposition, so that by some of the many natural modes of diffusion which are effective in this class of life, the organisms of the sea might be carried into land, as well as mixed in strata and deposits, along the courses of languid rivers? Probably so. The deposits of infusoria which now happen so abundantly at the mouth of the Elbe are mostly derived from the sea; and leaves that now occur in the River Hudson that species once imagined to be truly marine live in juxtaposition with the species of fresh waters. There may probably be, in a class of being associated with alluvial waters, a greater independence of habitat, as well as mixed in strata and deposits, which have little need of climate, and which require the extrinsic of lime from a state of solution in the waters which they inhabit. In confirmation of this view, we find the
sponge of the sea matched by the molluscan of fresh water, each extracting alia from the liquid, but the caulliferous plants, which are almost unrepresented in our inland lakes and streams. (Ehrenberg, Die Infusorienschen; Memoirs of the Berlin Academy, and Translations in Taylor's Scientific Memoirs; Read paper before the Royal Society.)

Ingen-Houz, Johan, a distinguished natural philosopher, was born in 1730. He was at an early age permitted to practice medicine in that city, and employed his leisure in the performance of experiments in chemistry and electricity; but, at length, quitting his native country he came to London, where he was received into the Philosophical Society, and soon attracted the notice of the English philosophers, and led in 1769 to his being elected a Fellow of the Royal Society. He had the good fortune to obtain an introduction to Sir John Pringle; and this celebrated physician, immediately appreciating his merits, warmly encouraged him in the prosecution of his researches, and honoured him with his esteem and friendship; he appears also occasionally to have corresponded with Franklin on the subject of electricity, which was, at that time, rapidly rising in importance.

The reputation of Ingen-houz as a physician must have been much increased by jeannette Maria Theresia, who lost two of her children by the small-pox, having directed her ambassador in London to consult Sir John Fringle respecting the choice of a physician whom she might invite to court for the purpose of inflaming the fire of the imperial family, Sir John, then president of the Royal Society, without hesitation recommended Dr. Ingen-houz: the latter, accepting the invitation, set out, in 1772, for Vienna, where he performed the operations with complete success. The example of the sovereign was followed by the nobility of Austria, and the children of the highest families of the country were inoculated by Ingen-houz or under his immediate inspection. The empress, in testimony of her sense of his merit and attention, gave him the titles of aulic counsellor and imperial physician; and accompanied these honours with the grant of a pension, which he enjoyed during the rest of his life.

During his residence on the continent, Ingen-houz visited Italy, France, and various parts of Germany; and, at intervals, continued to prosecute his researches in electricity and magnetism, and on the air produced by plants. While at Vienna, the emperor Joseph II. honoured him with especial notice, inviting him frequently to the palace, and occasionally visiting him at his own house, in order to witness the performance of his philosophical experiments. During a visit to Italy in 1773, Dr. Ingen-houz had an opportunity (at Leghorn) of making some experiments on the torpedo: he found that the animal gave the shocks most frequently when he stood or walked a few inches from it; being contained so strong that he was almost obliged to quit his hold, and he remarks that they resemble the discharge of a number of small Leyden jars through the hands.

About the same time he made the discovery that plants exposed to the light while growing, discharge oxygen gas from their leaves into the atmosphere; and an account of his researches relating to this subject was published in London in 1777, under the title of 'Experiments upon Vegetables, discovering the power of purifying the Air in the Sunshine and of injuring it in the Shade,' &c. The work was translated into French by the author, and published in Paris in 1780.

In the 'Philosophical Transactions' for 1779, there is an account of an electrical machine which, about that time, Dr. Ingen-houz had constructed; this consisted of several pasteboard disks, about four feet in diameter, which being covered with varnish were fixed upon an axis; between every two of them was a board covered on both sides with flannel and then with hare's skin; and the friction produced when the disks were revolved in an insulating vessel, gave rise to a spark between the machines sparks above a foot in length. This probably led to the invention of the plate electrical machine, which is generally ascribed to Ingen-houz; it consists of a couple of disks, 12 inches in diameter, placed between two cushions, forms a very elegant and, if made of considerable magnitude, a very powerful apparatus.

Dr. Ingen-houz published in English a work entitled 'New Experiments and Observations concerning various physical Subjects,' translated into French, and published in Paris. He also published, in French, a work entitled, 'Essai sur la Nourriture des Plantes,' which was translated into English and published in London in 1748.

Inobita, in law of Scotland, is a writ by which a creditor may proceed against those who are to whom he is indebted, either to favoured creditors or to other persons. Nomically it affects all property, but it is only in the case of heritable or real property that, from its standing on the register, it is efficacious. The privilege or the property on which it is to be founded on some obligatory written document, or established by the decree of a court. It may be recalled if improperly awarded. It conveys no specific security to the person who holds it, but it gives him a right to impinge every act which the debtor does to his prejudice regarding his real estate. It does not affect the validity of a sale for a fair price, but it gives the inquirer a right to draw the price so far as his debt extends. If the inhibition be followed by proceedings to attach the estate at the instance of the other creditors, the inquirer has a preference over them if the debts have been incurred subsequently to the inhibition, but not otherwise. The missus or inobita occasioned are of very intricate questions.

Injury, Injuries. As these words are vaguely used, it is as well to specify what is understand by Blackstone, after treating of Rights, proceeds in his Third Book (c. 1) to consider the wrongs that are forbidden and repressed by the laws of England. He then divides Wrongs into two sorts or species:—Private wrongs and Public wrongs. To Private wrongs he also gives the name of Civil Injuries, as being the infringement or violation of the private civil rights belonging to individuals considered as individuals. Public wrongs are 'a breach and violation of public rights and duties,' and 'are distinguished by the harsher appellation of Crimes and Misdemeanours.'

This is a confused statement. The true nature of Injury is however contained by the expression in Blackstone's commentary on what is Injury is necessarily prior to what may be termed Injury.

The English law has in fact adopted many terms of the Roman law; and if Blackstone had always traced their meaning correctly, he would have written less confusedly. As Jus is law, so Injury is something that is not Jus, or is forbidden by Jus. An Injury then, in the English law, is some illegal act; but the word is commonly used to express an illegal act done to a man or his property, for which he may by legal process get compensation. The English legal maxim that a man cannot recover damages or compensation when there is a damnum absque injuria, 'injuriosity' or 'uninjuriosity' for an injury or injury. The act must be an illegal act in order to entitle a man to compensation. If a man's acts damage the property of another, without being such acts as are forbidden, and for an act of science can get nothing in return, then, for instance, a man may act up a grocer's shop next door to another shop, and get all his neighbour's custom, which is a grievous 'damnum,' but no 'injury.' It is true that the nature of the damage may in some cases help to determine whether it is a legal injury or not; but the true question always must be whether the act complained of is either at common law or by statute, an unlawful act.

The Roman word Injuria, as already observed, signifies generally anything which is done contrary to law (quod non juris factum est, hoc est contra juris). In its narrow sense, Injuria was limited to unlawful acts that affected a man's person, not his property, at least not directly. It comprehended personal violence, such as beating a man, and using abusive words to him, and libelling him. Injuria might be done to a man either in his lifetime or after his death. For those who were in his power, as his children and slaves, or in his hand (manu), as his wife. The mode of proceeding was by the Actio Injurious. (Gosia, iii. 230-235.)

The nature of these injuries was to be ascertained. In injury to a man's person, it was to be determined by the court whether it was a legal injury or not. If this appeared, it was to be considered as an injury, whereas a wrong done to a man's property, or to his goods, was a wrong that was not an injury.

Injury, as such, is not a distinct species of civil wrong, but is to be regarded as a species of all wrongs, except Crimes and Misdemeanours. The Roman Injuria belongs both to the head of 'Law Criminal' and 'Law Civilian.' Vol. II.-M.
In some cases damages were got: in others, the offender was punished in his person: in some cases he might be punished by a pecuniary outcry and in his person also.

The common, the non-legal, use of the words injury, damage, &c., is so general as to involve notions of Bigot and Wrong generally. But people have often a clear perception that a damage is done for which no compensation can be got by legal means, though compensation is due according to the general principles on which the common notions of right and wrong are based. The popular judgment here is often right, and is a foundation on which good and efficient legislation can be securely based.

The possibility of inscriptions for the safe custody of the goods and chattels of their guests is one out of the numerous classes of cases that arise upon the law of bailments, and is placed by Sir W. Jones, in his Treatise, under the second subdivision, Locatio Operis, of the general head of Location.

The law makes the innkeeper responsible for the safety of the goods of persons coming to his house, in the language of the ancient writ, causid hospitandi; but he may be released from his liability either by inattention on the part of the guest to such reasonable rules as the innkeeper may think proper to lay down for the protection of the property of his guests; by any act of negligence on the part of the guest himself, or by his making use of the house not as it is before said, causid hospitandi. Thus, if an innkeeper requires his guest to put his goods under lock and key, and the guest leaves them in a passage, whereby they are lost; or the goods are put away in a less secure part of the house than the innkeeper himself had promised, he may not recover for the goods.

The subdivision of this general rule requires that the law should be made still more strict against innkeepers, as the good faith and responsibility of the innkeeper form the only security of the traveller. The Roman law on this subject is contained in the Digest iv., tit. 9. (Smith's Leading Cases, Caly's Case; Treatise on the Law of Bailments, by Sir W. Jones.)

INSANITY. (L. S. C. S.)

INSCRIPTIONS. (Inscriptions) is, records of public or private occurrences, of laws, decrees, and the like, engraved on stone, metal, and other hard substances, exhibited for public inspection. The custom of making inscriptions was infinitely more general in the states of antiquity than in any modern country, as we see from the innumerable inscribed monuments which still exist in Persia, Egypt, Greece, Italy, and other countries subject to or colonized by the Greeks and Romans. A great number of inscriptions, especially those recording great events, laws, or decrees of the government, which it was important for every citizen to know, supplied to some extent the want of the art of printing.

While the laws of the other cities or states, as illustrated by the regulations of the cities of Athens, Rome, and other great powers, were set up in public, this public exhibition was equivalent to their publication by means of the art of printing, for every Roman might go and read them, and, if he liked, take a copy of the same of his own use. Previous to the invention of the art of printing, inscriptions set up in a public place were the most convenient means of giving publicity to that to which it was necessary or useful for every citizen of the state to know.

Inscriptions therefore are, next to the literature of the ancients, the most important sources from which we derive our knowledge of their public, religious, social, and private life, and their study is indispensable for every one who desires to become intimately acquainted with the history of antiquity.

For the history of the languages they are of paramount importance, since in most cases they show us the different modes of writing in the different periods, and exhibit us to the language and progress of thought; and it is manifest that the ancients did not bestow that care upon the accuracy of the language and orthography which we might expect, and in many cases they seem to have left these things to the casual notice of the inscriber. After the fall of the Roman empire in the west, inscriptions still continued to be made very frequently; but as the ignorance of the middle ages increased, and as all knowledge became more and more confined to a few, the institution of making certain things known by means of inscriptions gradually fell into disuse, until the art of printing did away with it almost entirely.

In order to render inscriptions as permanent as possible, the ancients chose such materials as were least subject to destruction, viz. stone or metal. The stone most commonly used was marble cut in slabs, but sometimes inscriptions were engraved on clay; and in a few cases, common metal was brass or bronze, though we have instances also of lead, tin, and gold being used. If we believe the accounts of the ancients, inscriptions were made even in the mythical ages (H. v., 4; ix. 1, 1); but such inscriptions, existing in later times, were probably forged, and we cannot suppose that inscriptions were made until the art of writing was pretty generally known.

Greek Inscriptions.—The earliest Greek inscriptions which we may safely take to be genuine, but all of which have perished, were the lists of the victors in the Olympic games (Paus., iii. 21, i.; v. 4, 6, &c., the recents of the musical contests at Sicyon (Plutarch, De Mus., 3, 8), and the chronicles of the priestesses of Hera (Juno) at Argos. The earliest among the extant inscriptions do not seem to have been made much before the year B.C. 880.

All inscriptions are composed either in prose or verse, but the former compose by far the greater number. The prose of the public documents is usually still, and their style is not unlike that of official documents of our own time. All the inscriptions are written in capital letters, and without any punctuation or separation of the several words, which often renders it difficult to read and understand them properly. The ordinary are of the style. In some of the letters a guest uses his room in the inn as a show-room, in which a number of people are allowed to have access, and not as a lodging-room, the responsibility of the innkeeper.

The general interest seems to require that the law should be made still more strict against innkeepers, as the good faith and responsibility of the innkeeper form the only security of the traveller. The Roman law on this subject is contained in the Digest iv., tit. 9. (Smith's Leading Cases, Caly's Case; Treatise on the Law of Bailments, by Sir W. Jones.)

S. M. J.
building walls for the protection of the city. In the fourth century of our era religious fanaticism caused still greater havoc. Buildings were frequently used as building materials for all kinds of edifices; and if, in addition to all this, we consider the ravages of time and the destructive influence of rain and air, it is astonishing to see the number of Greek inscriptions that have been preserved down to our own time.

The first modern writer who conceived the idea of making a collection of ancient inscriptions was Cyprus. On the Ancona, who undertook, in a.d. 1620, a journey to Italy, Greece, and Asia Minor, and brought back a great number of inscriptions, which he collected in 3 vols. MS., which are still extant in the Bargello, but are said by M. Lenormant to have been subsequently lost. After Cyrus, a long time elapsed, during which the attention of the learned was chiefly directed towards Roman inscriptions. Silvio Maffei, and after him J. Casorelli and T. M. Rapino, formed the plan of a complete collection of all inscriptions, but none of them were able to carry it into effect, and people were satisfied with books containing such inscriptions as their authors happened to meet with, or thought of particular interest. Works of this kind are:—Janus Gruter, 'Inscriptiones Antiquae totius Orbis Romani,' Heidelberg, 1602, 2 vols. fol.; Marmora Arcauliana (also called "Oxoniensia," containing twenty-six Greek inscriptions in 1628, fol., by Peires, London, 1628, 4to., by Frideaux, Oxford, 1676, by Maittaire, London, 1732, and by Chandler, Oxford, 1765; Oct. Faberius, 'Inscriptions Athéniens Graeca et Latinae,' Rome, 1629, 8vo. vol. with a supplement, London, 1520, 4to.; J. Spon, 'Itinerarium in Italiam, Ilyricum, Graeciam, et Orientem,' Lugdun., 1753, 8 vols. Svo.; Thom. Reinæus, 'Synagoga Inscriptionum Antiquarum,' Lipsiae, 1629, fol.; W. Curtius, 'Inscriptiones Latinae Summorum,' London, 1651, Svo.; R. Fabreti, 'Inscriptiones Anticae,' Rome, 1699; A. van Dale, 'Dissertatio Antiquarum et Graecorum cum Romanorum Apulorum inscribenda,' Amsterdam, 1680, 4to.; F. Goeri, 'Inscriptiones Anticae Graecae et Romanae quæ extant in Extribus Urbibus,' Florence, 1737, 3 vols. fol.; J. A. Marturi, 'Novus Thesaurus Vetustatis Veterum,' Venice, 1739, fol. by S. Donati, Locca, 1765, &c., 2 vols. fol.; E. Curtini, 'Inscriptiones Atticae nune primum e Mafell Schedia edita,' Florence, 1752, 4to. The material collected in these works was greatly enlarged by the collections of inscriptions made by travellers, as Pococke, P. M. Paulaudi, Torremuzza, Passowei, Wallpole, C. Vidaus, and others. With the assistance of these further accessions, F. Osani began, in 1829, his 'Syllogorum Inscriptionum Antiquarum Graecarum et Latinae,' of which eight fasciculi in fol. appeared; and P. G. Weiheker published a smaller collection of metric inscriptions, 'Syllogium Epigraphum Graecorum ex Marmore recueilli,' Rome, 1828, 4to.

But in the meantime the Berlin Academy had formed the plan of publishing a complete collection of all the known Greek inscriptions, of which A. Boeckh undertook the editorship. The first volume of this 'Inscriptiones Graecae et Latinae,' vol. i. appeared in 1828, and besides the most ancient inscriptions, it contains those of Attica, Megaris, Peloponnesus, Boeotia, Locri, Phocias, and Thessaly; the second volume, which appeared in 1848, contains the inscriptions of Aescharnania, Epurus, Illyricum, the islands of the Ionian Sea, of Macedonia, Thrace, Samothrace, the islands of the Aegean, Rhodes, Crete, Cyprus, Caria, Lyais, Mycia, and Bithynia. This great work, in two hundred and twenty volumes, is now the most complete collection of Greek inscriptions. They are arranged, as appears from the above enumeration, according to the countries and localities in which they are found, and in each volume, the inscriptions of Athens, Boeotia, and Attica, have been judiciously classified into ten sections:—1. Acta senatus et populi, universitatum et collegiorum; 2. Tabulæ Magistratuum; 3. Tituli Honorarii; 4. Donationes Tituli et Operum Publicorum; 5. Orationes Oratorum; 6. Deificationes; 7. Monumenta privata, maxima quereluæ. It is partly owing to the influence which Boeckh's 'Corpus Inscriptionum Graecarum' exercised upon the scholars of our time, and partly to the latter being the first comprehensive collection of Latin inscriptions which he had made in his travels, and which had been communicated to him by his friends, in the second volume of his 'Roma,' I, 1839, reprinted in 1648, and at Helmstedt, 1860, fol., Martin Sauer's, 'Corpus Inscriptionum Graecarum,' has one volume which contains only inscriptions which he had collected during his visits in Italy; they are arranged according to the towns in which they are found, the publication of which is now still in guish between the earlier and later inscriptions, and he has some which are evidently not genuine. After that of Schrader followed that of Thom Reinæus, which was published

in the second volume of the 'Corpus Inscriptionum,' but others were published too late for inclusion, and will be published in a third volume. In the meantime, Boeckh prepared a supplementary volume of those subsequent works are:—Ph. Luchs, 'Inscriptiones Graecae et Latinae recuelliens in Graecia, Paris, 1836, &c.; Jansen, 'Musei Lugubri-Batavi Inscriptiones Graecae et Latinae,' Lugduni Batavorum, 1838, 4to., E. Curtius, 'Anecdota Delphica,' Berlin, 1843, 4to., the same, 'Inscriptiones Atticae nuper repertae duodecim,' Berlin, 1843, Svo., the travel of C. J. Leake, Fellows, and Hamilton; the work of M. Hort contains a large number of inscriptions from Asia Minor; and lastly Latronne, 'Recueil des Inscriptioh Graecae et Latinæ des Egypte,' vol. i., Paris, 1842, 4to., and the Philological Journal of Germany, France, and England.

Latia Inscriptiones.—These are not less numerous than those of Greece, and are found in great numbers at Rome, in Italy, and all the countries which were once subject to Rome. They embraced the same variety of subjects as the inscriptions in Greece, and if only the principal ones had been preserved the early constitution of Rome would be comparatively clear, whereas now there are a vast number of inscriptions to which we can only answer by conjectures. Some of the Roman writers have, it is true, made use of the most important inscriptions for the early history of Rome, but not by any means to that extent as those of Greece, where such inscriptions were enough to form the basis of all our knowledge. Roman writers do not appear to have been so much directed towards this source of information as that of the Greeks, for there is no instance of any collection having ever been made by the Romans themselves, although some of them were of the very highest importance in a constitutional as well as legal point of view. At the time of the overthrow of the Western Empire thousands of inscriptions must have perished, especially those engraved on the walls of people's houses, and the arches of the barbarians. But a great number was still preserved in Rome and Italy, which attracted the attention of the learned ever since the eleventh century. The oldest collection of inscriptions found at Rome, exists in the monastery of Einsiedeln; it is written on parchment, and probably belongs to the tenth or eleventh century. It is printed in Mabillon ('Vetustas Annuil., p. 358, &c.') At the time of the revival of letters, the attention of the learned was chiefly directed towards the authors of antiquity, but ever since the fifteenth century attention has also been bestowed upon inscriptions. The man who first formed the idea of a comprehensive collection was the above-mentioned Cyricus of Ancona, who undertook his travels at the request and the expense of Pope Nicholas I. The first printed collection of Latin inscriptions which is now extant is that of Deferens Papias, printed at Augsburg in 1651, and in its number, on seven folio leaves, under the title of "Romanas Vetustas Fragmata in Augusta Vindelicorum et eius Dioeœsit," in Augsburg, 1651. Another work, which is now extremely rare, was published by Laurentius Asterius, at Feni, of which a second edition by F. Polycandus appeared in the same year. The collection published by the bookseller Mancocci, at Rome, in 1526, in folio, under the title 'Epigraphi Antiqui Urbis Romae,' contains scarcely any other than sepulchral inscriptions.

After these collections of local inscriptions, B. Amantius and P. Apianus, supported by the liberal merchant Rallvand von Fugger, published a general collection under the title of 'Inscriptiones Sacrarumvetastris,' Ingolstadt, 1834, &c. Soon after, the learned George Fabricius published a considerable part of this collection of Latin inscriptions which he had made in his travels, and which had been communicated to him by his friends, in the second volume of his 'Roma,' Basle, 1560, reprinted in 1648, and at Helmstedt, 1860, fol. Martin Sauer's, 'Corpus Inscriptionum Graecarum,' has one volume which contains only inscriptions which he had collected during his visits in Italy; they are arranged according to the towns in which they are found, the publication of which is now still in guish between the earlier and later inscriptions, and he has some which are evidently not genuine. After that of Schrader followed that of Thom Reinæus, which was published...
A somewhat more complete and accurate collection of 4688 inscriptions was published by Fabrethi under the title 'Inscriptionum Antiquarum, quae in Aedibus Patrum asservantur Explicatio et Additamentum,' Rome, 1799, fol. (some copies date of 1702, but this is only a bookseller's impression).

But all the works here mentioned are eclipsed by the undertaking of James Gruterus, which was to contain all the inscriptions that had been made known. He took the work of Smeudis as his foundation, and was actively assisted by Joseph Scaliger. The collection appeared under the title 'Inscriptio Antiquae totius Orbis Romani,' Heldberg, 1631, fol. J. G. Grotefend afterward undertook to edit a still more complete and corrected edition, but he did not live to complete his task, which fell into the hands of F. Burmann, who, assisted by many other scholars, published the new edition of Gruterus, under the title 'Inscriptiones Antiquae totius Orbis Romani, in absolutissimam Corpus redactae, olim auspiciis J. Scaligeri et M. Velsleri, industriis autem Jani Gruteri, nunc notis Maruardii Gredi omnem. cura G. Gracoli,' Amsterdam, 1707, fol. Maruardi Gude, who had travelled in Italy, likewise prepared a collection of inscriptions for publication, which however was edited after his death by F. Hoesch, Leonardus, 1731, fol. This collection however contains many forgeries made by the notorious Ligorius. A collection of 2000 inscriptions which had been gathered by Doni, was published by Gori, 'T. B. Doni Inscriptiones Antiquae,' Florence, 1641. In 1739, he published 'Novarum inscrptionum Veterum Inscriptionum,' Milan, 1739, 4 vols. 4to., with a supplement by S. Donatus in 2 vols., Lucus, 1765, 8vo. Among the collections of inscriptions published at a later time, there are of great importance, with the exception of the selection from all the known inscriptions which was published by J. C. Orelli, under the title 'Inscriptio Latinarum selectarum amplissima Collectio ad illustrandam Romanae Antiquitatis Disciplinam accommodata, &c. cum ineditis Hagenbuchis suis Annotationibus,' Zürich, 1828, 2 vols. 8vo. This collection is extremely useful, but it is to be regretted that the editor has not always published the inscriptions with the accuracy and exactness which are required in works of this kind.

In modern times the number of Latin inscriptions found in the various parts of the world which once were subject to Rome, has been increased enormously, and will increase every year, as archaeological societies are formed in all parts of Europe, with the express object of searching after, preserving, and publishing the Roman monuments existing in the particular districts in which those societies are formed. The number of Latin inscriptions now known amounts to about 60,000, and the want of a new and complete collection has long been felt. Mr. Kellersmann, who has lived in Italy for some time, formed the plan of publishing a collection of Latin inscriptions similar to the 'Corpus Inscriptionum Graecarum' of Boeckh, but he died suddenly in 1843, before carrying out his plan. O. Johannes, who has passed his life in Italy, has formed a collection of all the known Latin inscriptions has recently been held out. On the 6th of July, 1843, Villenave, the French minister of public instruction, requested the Academies of Inscriptions and Archaology to prepare such a collection, and a commission of French savans has been appointed to conduct and superintend the work. Several pamphlets have since appeared both in France and Germany, containing suggestions respecting the principles which should be followed in the arrangement of the inscriptions.

Among the works to be consulted by those who wish to acquire a facility in reading and understanding Latin inscriptions, the following are of importance: Zaccaria, 'Institutiones Lapidariae,' Rome, 1770, and Venicis, 1792; Morcelli, 'De Stilo Inscriptionum Latinarum Liber Tertius,' Rome, 1751, and reprinted in his 'Opera Epigraphica,' Patavii, 1819, 5 vols. 8vo.; Kopp, 'Palaeographica Orbis,' Munisthal, 1829, 6 vols. 8vo.; and Orelli's Introduction to his Collection.

INSECTA, FOSSIL. Until within a few years the occurrence of insects in a fossil state could only be substantiated by a few number of well-verified instances (for instance in the beds of Aix in Provence) among lacustrine tertiary strata, or (as at Stonesfield in Oxfordshire and Solenohem in France) amongst marine oolite beds. But Mr. F. West with has added trees of coleoptera from the coal formation of Coalbrook Dale, and Mr. Strickland parts of neopterygia from the lips of Warwickshire; Dr. Buckland obtains neopterygia from the coalite of Stonesfield, and Mr. Brodie portions of insects belonging to various natural orders from the lips of Somersettshire, and of the limestone of the Vale of Wadour in Wilts, and the Vale of Aylesbury.

Still the number of fossil insects, whether we estimate individuals or species, is very small compared to the probable numbers which must have existed during a period of time so long. It is not improbable that a circumstance quite explicable by reference to the phenomena which are now taking place in nature; for, instead of 12,000 British species of insects there is reason to believe that but a very small proportion of the number have been created in the estuary, or marine depots now in progress. Only one eflytr of a small beetle was observed in a deposit of the Elephantoidea era in Yorkshire, and one seed of some umbellate plant, along with hundreds of shells which inhabited the lake.

No doubt vast numbers of insects, wandering by caprice or drifted by winds, pass from the shore and fall in the basins we learn from the first voyage of Cook, who sailed through myriad of insects, some on the wing and others in the water, thirty leagues from land off the coast of South America; but few of these escape the watchful finny races, or ever reach the bottom of the ocean. In like manner we find land insects hamped in profusion by winds on certain tracts of fresh water, and borne down the course of rivers by the sediments, the arching of the salt or fresh waters, or the drift of the estuary of the Wealden deposits, and in the tertiary accumulations of Aix, Oeningen, and Avignon. In the latter region, the subterranean cavities gathering on the intrusion of lavan or lava-cases of Phryganias have caused the formation of a peculiar limestone ("Iudialis Limestone").

In the following summary of the groups of fossil insects in Britain, the most recent stratifications come first. The catalogue commences with the Linnean era, the modern authorities and localities are given for each case. (See Morris's Catalogue of Fossils; Brodie's Fossil Insects; Lyeil, in Geol. Pro.; Phillips, Geol. Yorkshire, etc.)

1. Ostracous fresh-water deposits (Pleistocene).
   Elytron of a Chrysocera, Bellocia, in Yorkshire, (Phillips.)
   Remains of Copris lunaris. Mundesley, Norfolk. (Lyell.)
   " Donacia."
   " Gephyra.
   " Libralia."
   " Atherhas. Southwold, Suffolk. (Alexander.)
   (No true aquatic beetle is mentioned among these. Donacia haunts aquatic plants. The others are strictly terrestrial. They must have been drifted into the lakes in which the Plaenobia, &c. lived.)

2. In the Cretaceous System, no insects yet found.

3. In the Wealden strata of the Vale of Wadour (found by Mr. Brodie and transcribed by Mr. Wasson.)
   Aquatic Coleoptera of the families—Hydrophilidae? Diptera? (Colymbetidae.)
   Orthoptera, of the generas Achatia and Blata.
   Hemiptera and Homoptera, including land tribes, &c.,—Cicadina, Cicada, Corea, Larva., Aphides, &c., and the aquatic species of Vesu and Hydromyctera.

Neopterygia. In this water-bathing order occur Libellula and Zoelona, Corydalis, Libellula, Termes, &c. and Lepidocerae.

Trichoptera of Phryganias ?

4. In the olites strata, insects occur in the laminated earthy limestones of Stonesfield and similar localities in Gloucestershire and near Bath. Dr. Buckland has described several species in the Geological Proceedings and in his Bridgewater Treatise on Geology, and Mr. Brodie has added others. The remains are chiefly Elytra of Coleoptera.
and wings of Neoptera. The following is abstracted from Mr. Brodie's list.

Coleoptera, of the families Prionide, Buprestide, Filicole,
ranean, *Brentus*, mainly confined to the tropical regions of both hemispheres; *Apion* and *Rhyphocheta*, chiefly European. The distribution of the species of weevils depends in a great measure on that of their host plants.

The most beautiful and vividly coloured forms of Longicorn beetles are mostly tropical. The presence of forests determines that of many of the genera. Of the seventy genera of the family Cucujidae, twenty are of extensive distribution, and others are limited to the northern temperate regions. Others have defined centres, as *Clytus* in Europe, *Trachydera* in South America.

Of the Chrysomelidae, the typical genus Chrysomela is confined to the northern temperate regions. The distribution of certain plants determines the distribution of the species. From this cause, species of limited distribution are sometimes multiplied far from their aboriginal centres. Thus *Galeruca californica*, introduced from Europe into America, multiplied so at Baltimore in the years 1838 and 1839, that the elm trees of the district were eaten bare by their larvae, and probably they will henceforth become a constant annoyance in the New World. *Lema* and *Donacia* are instances of cosmopolitan genera having distinct centres in temperate climates. *Casida*, on the other hand, has its centre in the tropics.

Of the Trigidae, *Coccinellidae* are found everywhere. *Eumorphus* is Indian and Polynesian.

Orthoptera.—Though by no means an extensive order either as to genus or species, the Orthoptera are of very great importance. Many of the distinct genera of *Locust*, *Anacridium*, and *Acheta*, the grasshoppers and crickets, are found in most countries. The *Locusts* are mostly exotic. The strange *Phasme* are mostly tropical, as are also the greater number of the *Locustidae*. The wood-locusts, *Blatta*, are very general, and have been greatly diffused from their original centres by unintentional human agency. The weevig tribes, *Phyllophaga*, including more than fifty species, are in great part European, but range even to Van Diemen's Land.

Erichson notices the curious fact respecting the Orthoptera of Van Diemen's Land, that only one fourth of the species are winged and capable of active flight.

Neuroptera.—The number of known species in this order is short of one thousand. The section of *Placopenne* is almost entirely European; the genus *Macronema*, including species from Madagascar and Brazil, is an exception. The *Placopenne*, a great part of the genera of which division are now considered by many naturalists Orthoptera, have a much more varied distribution. Thus the *Myrmeleontidae* are cosmopolitan, the *Pterio* and *Nemoura* chiefly European, the *Pteropoda* characteristic of the temperate regions of both the old and new world, the *Periptera* of the tropics. In the section of *Scleruridae*, the *Ephemeroptera* are European; the *Aeshnidae*, comprising the families of *Aeshna*, *Libellula*, *Anax*, and *Aeschna*, to which near two hundred species are known. Other allied genera are more limited.

*Hymenoptera.*—Among the sting-bearing species, the true bees are by far the most important, these now dispersed in America having been transported from Europe. The genus *Centris* and *Euglossa* are exclusively American. *Nothocordylos* is south African. *Andrena*, *Xylocopa*, and several other extensive families are cosmopolitan. *Astrapia*, a great many genera of wasps are peculiar to South America. The ants are most developed in Europe. *Bembix* is a tropical genus. The terebrating Hymenoptera are both very numerous and widely distributed, especially the great genus *Ichneumon*. Certain genera forming the family *Oxyra* are exclusively European, as are also a great part of the numerous family of *Ostcalates*. *Cynipus* is European, and the greater number of *Tetraneura*.

The distribution of the *Strepsiptera* depends on that of the insects on which they are parasitic.

When the distribution of the butterflies shall have been worked out, it will doubtless prove very interesting. At present our knowledge of this subject is imperfect. The *Papilionidae* are very numerous specifically, and for the most part confined to the tropical regions. Some of them possess great ranges. Thus certain species of *Pieris* are found over all Europe, and great part of Asia and Africa. Other forms are constant to mountainous regions. Of the *Nymphalidae* the most extensive are the tropical ones. In this family there are some remarkable instances of extensive distribution of species. Thus *Vanessa Cardia* (a common British butterfly) is found in every part of the world, and *Vanessa Atalanta* is a familiar sight in every part of Asia, Africa, and to North America. In the remaining tribes the typical genera are almost always cosmopolitan, whilst others have more limited areas.

The *Sphingidae* and *Zygopidae* are in great part European; the *Gastropidae* are cosmopolitan.

Among the moths, the *Phalena* are chiefly European, and the species are usually widely distributed. This appears to be the case also with the other families of Nocturnal Lepidoptera. Of these we have as yet no extensive knowledge of exotic forms, than because it is really so, for we find types and species in distant regions wherever they have become accidentally introduced, as in the instance of Asiatic Russia, where the researches of recent years among these insects have brought many new forms to light.

*Diptera.*—One-half of the described species of two-winged flies (about eight thousand) belong to Europe. This disproportion arises from our comparative ignorance of the exotic species. The small group of *Ornithomyzidae*, parasites on quadrupeds and birds, has representatives of all its genera in Europe, the few remaining species being natives of eastern Asia, Western Africa, Australia, or Brazil. The flies forming the family of *Musciidae* include a great number of genera, both European and exotic, the former being most prolific in species, some of which have wide ranges, and are in the same category. The genus *Chrysopea*, equally developed in Europe and America, and represented in a less degree in Africa and Asia, does not appear in Australia nor in the islands of the Pacific; *Tabanus* is more widely distributed. *Ommatius*, a genus of *Asilidae*, has its members in all parts of the world. A great many genera are peculiar to South America, and several to Africa, hot, woody, and moist regions being specially the abode of the numerous and varied forms in most parts of the world, is excluded from Australia and the Pacific, which region seems to be the least prolific in *Diptera*. *Oxylus* is generally distributed.

*Hemiptera.*—Of the two great divisions of this order, the *Hemiptera* and the *Heteroptera*, the first is the smallest and also the most tropical. The distribution of the insects corresponding to the tree species that form the fauna and flora of the countries they inhabit. Thus each species of *Coccus aphid* has a range correspondent to that of the plant upon which it feeds; and of the *Coccidae* and *Lopadinae* with the presence of their favourite animal food. Among the most interesting of the families of *Hemiptera* are the *Cicadidae*, of which the genus *Tettigonia* includes 200 species, centred in America, but having members also in the Old World; the *Peloridea*, or *Lantern-flies*, very generally distributed through warm climates; *Scutelleria*, remarkable for brilliancy, and mostly equatorial; and *Cimex*, of which the only true species is the common bed-bug, a pest spread over all Europe. Of the *Aphididae* the *Vasconia* are cosmopolitan, *Palorus* and *Nectonemia*, mostly European; *Galbus* and *Mononyx*, American; and *Holobotes*, equatorial.

*Thysanura.*—Yet the distribution of these minute insects has been less extensively determined. The more typical range from Europe to China. *Padura* and *Sphingida* are European; a single species of the last-named genus occurs in North America.

*Anoplura.*—These disagreeable parasites have lately been honoured by the attention of some excellent naturalists, especially Dennys and Gwilt. Their distribution corresponds with that of the animals upon which they are found. Of the equally annoying order *Aphaniptera* three-fourths of the known species are European. The common flea is a cosmopolitan, and the Chigo is confined to South America.

IN SOLVENCY. From August, 1849, to August, 1845, three acts have been passed relating to insolvent debtors; these are 5 & 6 Vict. c. 116; 7 & 8 Vict. c. 96; and 8 & 9 Vict. c. 127.

The acts are & 6 Vict. c. 116, which came into operation 1st November, 1842, enabled a person who was not a trader within the meaning of the bankrupt laws, or a trader who owed debts which amounted in the whole to less than 3000l., to present a petition to obtain an order of the court to make an order for bankruptcy in London or the Commissioners of the District Courts of Bankruptcy in the country, from all process whatever (except under a judge's order), either against his person or property unless they are prior to the order. If the interim of the insolvent's property was vested in an official assignee appointed by the court. If, on the hearing of the petition, the commissioner was satisfied with the allegations which it contained, and there was not a breach of trust, or by any proceedings for breach of the laws,
he was empowered to make a final order for the protection of the petitioner from all process, and to cause his estate and effects to be sold in aid of his assignees, together with an assent chosen by the creditors.

The act 7 & 8 Vict. c. 96, passed 9th August 1844, is entitled 'An act to amend the law of Insolvency, Bankruptcy, and Assignments, to provide for such cases as may be committed to court for adjudication under an order of court, and to provide for a pecuniary security for the purposes of such orders; and for such purposes as to the said order may be annexed; to provide for the ascertainment of the title of the said debtor; and to extend the jurisdiction of the courts for the recovery of debts in insolvency cases.'

The property of the insolvent may be seized for the benefit of his creditors with the exception of the wearing apparel, bedding, and other necessaries of the petitioner (the insolvent under § 7 & 8 Vict. c. 96), and his family, and the working tools and implements of the petitioner not exceeding in the whole the value of 20L. Under the § 7 & 8 Vict. c. 96 (§ 39) if a petitioner for protection from process (pursuant to the provisions of that act) shall wrongfully and fraudulently omit in the schedule, which schedule he is required to make (§ 5 & 6 Vict. c. 116), any property whatsoever, or retain or exempt out of such schedule any wearing apparel, bedding, or other necessaries, property of greater value than 20L, any debtor, upon conviction, be liable to be imprisoned and kept to hard labour for any period not exceeding three years.

The act 7 & 8 Vict. c. 96, made a great alteration as to debts under 50L. of the 57th section of W. Wilberforce Act of 1840, which was in expedient to limit the present power of arrest upon final process, be it enacted, That from and after the passing of this act, no person shall be taken or charged in execution upon any judgment obtained in any of the Majesty's superior courts, or in any county court, court of requests, or other inferior court, in any action for the recovery of any debt wherein the sum recovered shall not exceed the sum of 20L exclusive of the interest and costs of action; and the said 57th section is hereby repealed so far as it relates to debtors of the value of 20L and upwards, whereby the act provided that upon application to a judge of one of the superior courts of law at Westminster, or to the court in which such judgment as is mentioned in section 57, shall have been obtained, all persons in execution at the time of passing this act be discharged, when the debt, exclusive of costs, did not exceed what is specified in the 57th section. Accordingly, such persons, on making application pursuant to the 56th section of this act, were discharged from prices in England and Wales.

The consequences of the legislation contained in the 57th and 58th sections of 7 and 8 Vict. c. 96, were those. All persons who were in confinement for debts under 20L, exclusive of costs, might get their liberty; but the judgment upon which the debtor was taken in execution remained in force (§ 58.), and the judgment creditor or creditors had their remedy and power to do whatever was necessary to enforce the property of the debtor, just as they might have had if he had never been taken in execution upon such judgment. The 58th section gave to the judge who should try such cause (§ 58), power to order the insolvency or bankruptcy of the debtor, and power to imprison the defendant (depositor) for such times as are mentioned in § 58., if he should appear to have been guilty of fraud in contracting the debt, or had contrived it under the other circumstances mentioned in the 58th section.

The amount of debts in England and Wales under 20L. must always form a very considerable proportion of all the debts that are at any time due in England and Wales. Such debts comprehend a large part of the dealings of shopkeepers and petty traders; probably in a very large number of cases debts under 20L. may never come into court, nor be the subject of any judgment or execution. In many cases give credit to persons who have no reasonable means of payment, and with whose character and condition they are imperfectly acquainted. Many persons are always in the position of debtors for the recovery of debts; and in the hands of non-professional creditors or those who are not familiar with the consequences of non-payment. A third class, which we hope may be the most numerous of all, is willing to pay, but often requires time, and must be deprived of many comforts if they do not continue to pay their creditors and earnings fairly entitle them to. [Carruth, P. C. S.]

The 57th and 58th sections of the 7 & 8 Vict c. 96, deprived creditors of their hold upon their debtors for sums under 20L, and left to all persons who had claims upon persons indebted for sums under 20L. to the recovery of their debts there. As to debts under 20L. existing before the act, and for which the debtor was not in execution, it left the creditor no remedy except against his property. And here is the great alteration which the act made. In the case of debtors seems reducible within narrow limits, if we view it merely as it affects the interests of the community. The object in allowing a debtor to be seized is not to punish him as a debtor, but that he may be sufficiently restrained by a complete execution for the purpose of discovering what his property is, that he has not parted with it to defraud his creditors, and that there was no fraud in the contracting of the debt. The simple fact of being seized and unable to pay or not would not be punished. The contracting debts under such circumstances as amount to fraud ought to be punished. The principle then which should guide a legislator should be, not to punish a man simply because he is indebted and cannot pay his debts, but to punish him for any fraud that is committed either in contracting the debt or in attempting to evade the payment of it. Now in the case of a debtor, fraud, both in contracting a debt and in attempting to evade payment, is known by experience to be a thing of frequent occurrence; and it is therefore just and reasonable that judgment creditors should have the power to secure the person of their debtor until he has paid his debts or made a full and honest statement of his means of payment.

The effect of the last-mentioned act was of course to diminish the credit given by small dealers to all persons. The act has also relieved many small traders and debtors from the act, in order to secure the person of their debtor until he has paid his debts or made a full and honest statement of his means of payment.

The legislature have now remedied the mischief which they have created by a new act, called the 8 & 9 Vict. c. 127, which gives to creditors the means of obtaining payment except by an action in one of the superior courts, in which case the creditor would have to pay the costs out of his own pocket, and in the end might be unable to obtain satisfaction for the debt. Many tradesmen had debts in sums of less than 20L. which in the aggregate amounted to a large sum, perhaps in some cases to 2000L. or even 3000L. in some of the provincial towns. The aggregate amount owing in sums under 20L. was not less than 100,000L.

The act 8 & 9 Vict. c. 127 gives to creditors the means of obtaining payment either by an act of bankruptcy, or by an act of insolvency, or by an act of bankruptcy and insolvency, or by a petition for the recovery of debts in insolvency cases. The powers of the act extend to debts of a value of 20L. and upwards.

The act (8 & 9 Vict. c. 127) gives to creditors the means of obtaining payment of sums under 20L., besides the costs of suit, by the following process:—A creditor who has obtained judgment, or order for the recovery of any debt, whether exclusive of costs, may summon his debtor before a commissioner of bankruptcy; or he may summon his debtor before any court of requests or consistory, or inferior court of record, or the judge or barrister-at-law, a special pleader, or an attorney of ten years' standing. It may here be remarked that this part of the act which takes the jurisdiction of the courts of bankruptcy and of other courts over the matters of insolvency is a new provision.

The judges of these courts are made removable for misconduct or disqualification, and the courts will be assisted in some degree to the bankruptcy and insolvent courts.

On the appearance of the debtor before the commissioner or court upon summons, he will be examined by the court,
or by the creditor if he think fit, 'touching the manner and time of his contracting the debt, the means or prospect of payment he then had, the property or means of payment he still hath or may have, the disposal he may have made of any previous contracts, etc.' and to make an order on the debtor 'for the payment of his debt by instalment or otherwise,' and if the debtor fails to attend or to make satisfactory answer, or shall appear to the satisfaction of the judge that the debt is not due, the court shall have willy-nilly contracted it without reasonable prospect of being able to pay it, or to have concealed or made away with his property in order to defeat his creditors, the commissioner or a commissioner, as may be directed by the court, shall by an order in writing, in the way above stated, arrest the defendant, and imprison him for forty days; but such imprisonment will not operate in satisfaction of the debt. Wearing apparel and bedding of a judgment debtor, and the implements of his trade, amounting in the whole to a sum not exceeding 2l. in value, are exempted from seizure. The powers of all inferior courts under this act are assimilated; and a suit commenced in one small debt court cannot be removed to another similar court in the same town. When a debt exceeds the suit may be removed by certiorari to the superior courts. Any of her Majesty's secretaries of state are empowered to alter or enlarge the jurisdiction of all small debts and inferior courts. The act itself authorises the provisions of resolutions where sums not exceeding 2l. could heretofore only be recovered, and now sums not exceeding 20l. may be recovered in small debt courts by the act that all suitors' money paid into court and not claimed by the time specified by this act is to go into a fund for the payment of the necessary expenses of carrying on the business of the court.

The regulations of the 7 & 8 Vict. c. 06, as to debts under 20l. caused universal dissatisfaction among creditors in England and Wales, as we have already observed. The evidence taken before the Lords' Committee in 1846 proved the necessity of this act. The Judges Olympic in all countries have an unreasonable legislation and of its correction is useful. It shows how ill-considered measures sometimes become law in this country, in which the mass of public business is so enormous. The act is to extend five years, and is to be renewed by Parliament, and is to contain a provision for the future payment or the compromise of his debts, and a statement of his assets and debts. Any one of the commissioners of bankruptcy may examine the petitioning creditor, or any creditor who may join in the petition, or any witness produced by the debtor, in private; and if he be satisfied with the statements made, he may convene a general meeting of all the petitioning creditors, and appoint an official assignee, registrar, or a creditor to report the proceedings. If at the first meeting the major part of the creditors in number and value, or nine-tenths in value, or nine-tenths in number of those whose debts exceed 20l., shall assent to the proposition of the debtor, the proceeding is to be supported by a statement in writing of the creditors in number and value, or nine-tenths in value, or nine-tenths in number of those whose debts exceed 20l., and the meeting of creditors is to be unanimous, and that the arrangement made shall be binding, provided one full third of the creditors in number and value be present. Under this arrangement the affairs of the debtor may be settled. When this has been effected, a meeting of the creditors is to be held before the commissioner, who is to give the debtor a certificate, which shall operate as a certificate under the statute relating to bankruptcy.

The great arguments in favour of the Supplementary Paper on Bankruptcy and Insolvency, by William John Law, Esq. Dissenting from the Report. Presented to both Houses of Parliament, 1841. Mr. Law did not sign the report of the other commissioners on the appointment of the committee, but he did not agree with them; and the Supplementary Paper contains the reasons of his dissent. With respect to arrest in execution, Mr. Law's intimate knowledge of the relations of creditor and debtor has enabled him to answer fully all the arguments of those who attempt to show the insufficiency of this final arrest. He has proved beyond doubt the justice of this final arrest, or if the word justice be objected to, its usefulness to the community. A man is not now arrested till he has disobeyed the judgment of a court of justice. It is his business to show why he disobeyed the judgment; and in the mean time either his person must be secured, or the judgment executed as a mere idle form. It may be said, the plaintiff can proceed to take the debtor's property: but even visible property cannot always be got at; for when the sheriff goes to seize it, he finds it has been secreted already. If the security is a mere bill of sale, and frightens him out again; there is not one plaintiff in five hundred, great or small, who has courage enough to indemnify the officer, and defy the fraud. If there is any difficulty in the terms of the judgment, the question is, what must be the difficulty of getting at the property of the debtor which is not visible? And what other mode can be suggested of compelling the defendant to give a true account of all his property than the imprisonment until he does? 'A defendant has always been prone to place his property out of reach of an execution, but there has been this one restraint: he says to himself, If I make my property safe, they will take it, and then I must bring it forward.' When property only can be touched, the argument is changed; it becomes this: 'If I make my property safe, my enemy can do nothing.' So necessary is process against the property of the defendant, that the court has declared it to be his duty to require of the creditor by record the establishment of any further case, in order to entitle him to an execution. His judgment is his case: the clearest duty lies on the other party to establish his exemption from the task of satisfying it. The great argument of the Report from which Mr. Law dissents is this: that all execution against the person presumes the value of the debt. The greatest argument is, that the question ought to be against the debtor who does not obey the judgment of the court. He may be guilty of fraud or he may not: it is his business to explain why he discloses the property, if the order is not made on sufficient cause. The execution is founded on the presumption being in the debtor's favour, instead of being, as it is, against him. 'The practical justice and wisdom is in subjecting all (debtors) to searching inquiry, poorly.
for the purpose of ascertaining whether they are dishonest or not. I am quite sure that in that court (the Insolvent Court) where searching inquiry is known and practised, it is found necessary to confine ourselves to what is most useful in operation, as a summary for the advanced student, not an explanation for the learner. Properly speaking, the problem requires some addition to make it definite. The 2r has $x^2$ for a primitive function, and also $x^2+C$, C being any constant quantity whatever. In the present article, we shall neglect this constant altogether, reminding the reader that he must never omit it in any application. If he should find in different books different functions given as the primitives of one and the same function, he will always find that those different primitives differ only by a constant quantity. Thus $(1-x)^{-1}$ and $x(1-x)^{-1}$ both occur as the primitives of $(1-x)^{-2}$; but they only differ by a constant, namely 1.

In the common process of integration, the actual passage from the differential coefficient to the primitive is always an act of memory. The algebraical work which occurs is always used either to reduce a form in which memory will not serve into one in which it will, or else to reduce the given differential coefficient to two terms, one of which can be integrated by memory, and the other of which is more simple than the original quantity.

The functions in which the simple remembrance of the forms of the differential calculus is of use are as follows:

$$\int dx, \int f(x) dx = \frac{x^2}{2} + C$$
$$\int f(x) dx = \frac{x}{c}$$
$$\int f(x) dx = \cos x, \int f(x) dx = \sin x$$
$$\int f(x) dx = \tan x$$
$$\int f(x) dx = \sec x$$
$$\int f(x) dx = \csc x$$
$$\int f(x) dx = \cot x$$
$$\int f(x) dx = \sec x \tan x$$
$$\int f(x) dx = \csc x \cot x$$

To these should be added the following, which may be obtained in various ways from the methods of this article, or from peculiar articles which are found in works on the subject:

$$\int f(x) dx = \frac{x}{c}$$
$$\int f(x) dx = \frac{x}{c}$$

Among the peculiar articles of integration may be reckoned the following, which are perhaps nearly all that can be useful to a learner:

1. The reduction of such a form as $f(x)dx$ to another form $vdx$, in which $v$ is a different variable. Thus $f(x)dx$ can be immediately reduced to $\int f(x)dx + C$. The second form is immediately seen to be integrable. Cases of this kind are so various that the student must form the habit of looking for them, and recognising them at sight. Sometimes a slight transformation is required, thus: $(1+\alpha/x)^{-1}dx$, when reduced to $(1+\alpha/x)^{-1}dx$, which is $\int (1+\alpha/x)^{-1}dx$ clearly shows the form $v^{-\alpha}dx$, where $v = x^{-\alpha}$.

2. The reduction of algebraical to trigonometrical functions, and the converse. Thus $(a-x)^{-1}dx$, if $x$ be made a $\sin \theta$, becomes $a \cot \theta + C$. The second form is immediately seen to be integrable. Cases of this kind are so various that the student must form the habit of looking for them, and recognising them at sight. Sometimes a slight transformation is required, thus: $(1+\alpha/x)^{-1}dx$, when reduced to $(1+\alpha/x)^{-1}dx$, which is $\int (1+\alpha/x)^{-1}dx$ clearly shows the form $v^{-\alpha}dx$, where $v = x^{-\alpha}$.

3. When rational powers appear in a denominators, they
should be transferred to the numerator by changing \( z \) into \( 1: z \). By such a transformation, we change \( \frac{dx}{\sqrt{a+bx+cz^2}} \) into \( \frac{r^{m-1}ds}{\sqrt{a+bx+cz^2}} \).

4. When an irrational root of a polynomial appears in the numerator, it should generally be transferred to the denominator: thus, \( J \int dx \) should be written \( \int J \frac{dx}{X} \). By such a transformation, we change

\[
J = \frac{\int a dx}{\sqrt{(a+bz+cz^2)}}
\]

the first term of which can be integrated as in (1), leaving the second term, which can be simply integrated.

5. The process known by the name of integration by parts, consists in reducing the form \( J \int dx \) into an arbitrary form \( \int x dx \), and using the obvious theorem

\[
J \int f(x) dx = \int f(x) dx - J \int f'(x) dx
\]

the finding of the first integral is reduced to that of finding the second integral, which may often happen is the more simple of the two. Thus to find \( \int e^x \log x \) we have

\[
\int e^x \log x \, dx = \int e^x \log x \, dx - \int e^x \, dx
\]

about the second term of which there is no difficulty. But it often happens that this method succeeds by a succession of reductions. Thus it gives

\[
f(x) \, dx = x^a - \frac{1}{a} f(x) \, dx
\]

in which the second term must be again treated in the same manner.

6. In the last mode of proceeding, it is best to form, in general terms, an equation of reduction, as it may be called, which furnishes the key to the reduction of each case to the one below it. Thus if \( \int f(x) \, dx \) be considered as a function of \( n \), and called \( V_n \), integration by parts gives

\[
V_n = a^n x^a - na^{n-1} V_{n-1}
\]

thus showing how to find \( \int f(x) \, dx \) as soon as \( \int f(x) \, dx \) is known.

7. The use of the equation of reduction depends upon our being able at last to reduce the question to that of finding a visibly known integral. Thus, if in the preceding \( n \) be an integer, we must at last come to \( \int f(x) \, dx \) or \( \int f(x) \, dx \) which is known. But if \( n \) were a fraction, no function of the value of \( n \) at a time would lead to an integrable form.

8. The integrable form at which we arrive by successive reductions is called the ultimate form. It frequently happens however that the reductions proceed by two or more steps at a time, in which case two or more ultimate forms result. For instance \( V_n = \int \left( f(a-x) - \frac{1}{n} f(a-x) \right) \) has for its reduction of equation

\[
V_n = - \frac{x^{n-1} f(a-x)}{n} + \frac{1}{n} f(a-x)
\]

Accordingly, when \( n \) is even, we are brought at last to \( V_n \), and when \( n \) is odd, to \( V_n \), or to \( \int \frac{1}{n} (f(a-x) - a) \) and \( - \int (f(a-x)) \). In using equations of reduction, it will be found more convenient to work upwards from the ultimate form to the case required, than in the contrary way. Thus if we want \( \int \frac{f(x)}{\sqrt{(c+bz+cz^2)}} \), the equation of reduction being

\[
\int \frac{f(x)}{\sqrt{(c+bz+cz^2)}} = \frac{1}{a} \int \frac{a f(x)}{\sqrt{(a+bx+cz^2)}}
\]

we should proceed as follows:

\[
\begin{align*}
V_0 &= f(x), & V_1 &= a f(x) - f(x) \\
V_2 &= a^2 f(x) - 2a f(x), & V_3 &= a^3 f(x) - 3a^2 f(x) + 2a f(x) \\
& & V_4 &= a^4 f(x) - 4a^3 f(x) + 12a^2 f(x) - 24a f(x) + 24 f(x)
\end{align*}
\]

11. There are several cases in which the following extension of the theorem known by the name of John Bernoulli may be used to advantage. \( a', a, b, c \), be the successive differential coefficients of \( u \) with respect to \( x \), and let \( v_1, v_2, v_3, \ldots \) be the successive integrals of \( x \) with respect to \( x \) then

\[
\int f(u) = x_1 v_1 + x_2 v_2 + x_3 v_3 + \cdots \pm \left( x_1 v_1 + x_2 v_2 + \cdots \right) \frac{x_m}{(m+1)!} f^{(m+1)}(x_m) \, dx.
\]

This is particularly useful when \( a \) is a rational and integral function, and \( u \) is successively integrable with respect to \( a \), in a manner similar to the process in Ex. 100. Ex. 100, Ex. 101, and Ex. 102. It may then be continued until the result is obtained.

12. In the case of \( \int f(x) \, dx = \int \frac{dx}{x} \), when \( x \) are rational and integral functions, the integration is always possible as soon as all the roots of \( x \) are found. The process in Ex. 100, Ex. 101, and Ex. 102. It may then be continued until the result is obtained.
Let $V_a = \frac{m}{a}$ and $V_b = \frac{n}{b}$ in the preceding formulae.

If $m$ and $n$ are of the same sign, the formulae are most commonly used.

The preceding formulae involve the functions $\sin n$ and $\cos n$, the integral form of which is given by

$\int \sin n \cos n \, dx = \frac{\sin (n-1) \cos (n-1) - \sin (n+1) \cos (n+1)}{2(n-1)}$.

If $m$ and $n$ are of opposite signs, the formulae are also most commonly used.

Let $X = \frac{m}{a}$ and $Y = \frac{n}{b}$, then

$\int \sin m \cos n \, dx = \frac{\sin (m+n) \cos (m-n) - \sin (m-n) \cos (m+n)}{2(m-n)}$.

For $m$ odd and $n$ even, the formulae are also most commonly used.

Let $X = \frac{m}{a}$ and $Y = \frac{n}{b}$, then

$\int \sin m \cos n \, dx = \frac{\sin (m+n) \cos (m-n) - \sin (m-n) \cos (m+n)}{2(m-n)}$.
92

\[ \frac{1}{(m-1)s^{m-1} + n-1} \int \frac{dx}{s^m + x^n} = \frac{c^{-1}}{(n-m)s^{n-m} + n-n} \int \frac{dx}{s^n + x^n} \]

\[ \int \frac{dx}{s^m + x^n} = \frac{1}{(m-1)s^{m-1} + n-1} \int \frac{dx}{s^m + x^n} \]

\[ \int \frac{dx}{s^m + x^n} = \frac{1}{(n-1)t^{n-2} - m-1} \int \frac{dx}{s^m + x^n} \]

\[ \int \tan^n \vartheta \, d\vartheta = \frac{\tan^{n-2} \vartheta}{n-1} - \int \tan^{n-2} \vartheta \, d\vartheta. \]

We have given the last steps in various forms, because in fact all the integrals of the form \( \int \frac{dx}{(a^x - b^x)^2} \) depend upon them. For \( \pi = \sin \theta \), the last integral becomes

\[ -a^{n/2} \sin^2 \theta \, d\theta. \]

We have now given most of the forms which will be useful in the ordinary work of reference. Further forms and examples will be found in many works on the integral calculus, but the largest collection is in Euler Hirsch's 'Integraltafeln,' Berlin, 1910, 4to, a work of which there is also an English edition.

We have noticed a great many such forms as \( \int \frac{dx}{a^x + b^x}, \int \frac{dx}{a^x - b^x}, \) etc. which are little used, except in particular cases. When \( a = b \), these forms can be integrated, it follows that \( \int \frac{dx}{a^x + b^x} \) and \( \int \frac{dx}{a^x - b^x} \) can also be integrated, since the second can be made into the sum or difference of two functions of the first kind, by putting for \( a \sin \theta \) or \( \sin \theta \) their exponential values.

The question of the possibility of integration in finite terms can often be settled by the following theorem:—Integration and differentiation, with respect to different variables, are convertible operations; thus

\[ \frac{dy}{dx} = \int \frac{dy}{dx} \, dx. \]

If therefore \( \int \frac{dy}{dx} \, dx \) can be found, so also can \( \int \frac{dy}{dx} \, dx \) if \( y \) be not a function of \( x \). From this it will be seen that whenever \( \phi(x) \) is an integral so can \( \phi(x) \, dx \), which is obtained by \( n \) differentiations with respect to \( a \) and also that whenever \( \phi(x) \, dx \) can be integrated, so can \( \phi(x) \, dx \), which is obtained by \( n \) differentiations with respect to \( \int \phi(x) \, dx \) for \( \int \phi(x) \, dx \) being an integral [Napierian].

Functions involving the transcendental forms \( \sin_x \phi, \phi_x \), etc. can sometimes be reduced to more algebraical forms by integration by parts. Thus,

\[ \int V \sin^n X \, x \, dx = \int V \sin^n X \, dx \ablX^a \]

\[ \int V \log X \, dx = \int V \log X \, dx \ablX^a. \]

INTEGRATION, DEFINITE. In the preceding article we have given some idea of the usual modes of integration. The results, which in the present article are given under the name of definite integrals, are mostly cases in which it is possible to find an integral when both limits are given [Integral Calculus, P. C.]; but not possible to find the integral in all cases. If we can integrate \( \phi(x) \, dx \) generally, that is, if we can find the function \( \phi(x) \), of which \( \phi(x) \) is the differential coefficient, we can always express the integral, the limit of the summation in the article just referred to, as follows:

\[ \int \phi(x) \, dx = \phi(b) - \phi(a). \]

It frequently happens that \( \phi(x) \) is a function for which this cannot be done in a finite form, except for certain values of \( a \) and \( b \). And it happens almost as frequently that those practicable values are of particular importance.

But the view of definite integrals which best shows their utility is the consideration of them as fundamental modes of expression. The ordinary symbols of algebra, it is well known, are incompetent to express in finite terms by far the greater number of integrals. Consequently the integrals themselves become modes of expression, and frequently the only ones. When we find a language with which we have much to do, and which has words which cannot be translated, we adopt the words of that language into our own. Precisely the same thing is done in the case of definite integrals. Thus in factorials, P. C. S., we adopt the integral \( \int e^{-x} \, dx \), as the fundamental mode of expression for a function till then inexpressible, which becomes \( \int e^{x} \, dx \) whenever \( x \) is an integer, and remains intelligible, though not very easily found, when \( x \) is a fraction.

Further to illustrate this, let us suppose that the integral calculus had made some progress before the conception of a logarithm had been formed; a thing which might easily have happened. It would then have been found that \( e^{-x} \) was wholly unattainable, a function which algebra could not express in finite terms. It would therefore itself have become a mode of expression, and it would soon have been proved that

\[ \int e^{x} \, dx = \int e^{-x} \, dx + \int e^{x} \, dx. \]

Here then would have been an obvious indication of the existence of a function proper to be made use of in performing multiplication by means of addition, etc.; and tables of the values of \( e^{x} \, dx \) would have been formed by the method of quadratures [Quadratures, P. C.] or otherwise; which, would, so it happens, have been a much easier task than that which fell on the first calculators of logarithms. For all this to have happened, it had only been necessary to know the logarithms and their properties; so that \( e^{-x} \, dx \) is seen to be the logarithm of \( x + c, \) and \( e^{x} \, dx \) is the logarithm of \( x + c, \) throughout this article being Napierian. But we are not equally ready for \( f(x) \, dx \), or for \( f(x) \, dx \) (except when \( x \) is a integer) or for \( \cos x \, dx \), and accordingly we are obliged to study the properties of these functions as fundamental modes of expression.

To give some idea of the use of this view, we exhibit a mode of solving the following partial differential equation, \( \frac{du}{dx} = a \, dt. \)

The general solution of which cannot be expressed in finite terms. It will easily be seen that \( C \, e^{x+a} \) is a solution for any value of \( C \) and \( \psi \), provided only that \( \mu = \psi \), and also that the value of \( C \) is such that \( \psi \) is a solution. Hence we assume an indefinite number of such terms, giving to \( C \) the form \( \psi \), and summing them with such values of \( C \) as will make the whole represent

\[ \int \psi \, dx. \]

and we then see that this integral is a solution or general value of \( u \), whatever the function \( \psi \) may be, and whatever may be the values of \( C \) and \( \psi \). By a reduction which is rendered easy by some of the results presently mentioned, this solution is thrown into the form

\[ u \, = \, \int \psi \, (x + 2 \sqrt{a}) \, e^{x+a} \, d\psi. \]

where \( \psi \) may be the symbol of any function. From this it is clear that the given differential equation has numberless solutions which ordinary symbols are incapable of expressing in finite terms. The treatise in the Library of Useful Knowledge on the Differential Calculus, Gregory's 'Examples of the Differential Calculus,' and the 'Cambridge Mathematical Journal,' contain various examples of this mode of expression applied to differential equations.

We now proceed to give a selection from the enormous number of definite integrals which has been given. They have been found by detached methods, so that we could not attempt to give anything more than the results. Our article is intended for reference to the forms which it is probable will be found in future elementary treatises, for which the mathematical reader may also wish to refer. In order to avoid risk of broken or dropped letters, in an article in which the correct printing of the limits is the utmost importance, we shall print what is usually denoted by \( \int \phi(x) \) in the following way, \( f \phi(x) \int (a, b) \). Any conditions as to the values of constants will be expressed before the integral.
INT

It need hardly be said that the article FACTORIALS, P. C. S., must be considered as a part of the present one.

Among the integrals which clearly depend on, or are connected with, factorials, are the following:

\[
(m+1 < n) \int x^{m-1} e^{nx} \, dx = \frac{x^m}{m n^{m-1}}.
\]

\[
(m + 1 < n) \int x^{m-1} \cos nx \, dx = \Gamma(m+1) \frac{1}{n(m-n)}.
\]

There is a class of multiple integrals closely connected with factorials, which may be made to save much trouble in applications to geometry. We shall take three variables as a specimen, but the same formula may be written with any number. The triple integration being made for all positive values which give \( x+y+z \) exceeding 1, we have (a, b, c, being positive)

\[
\int_{x=1}^{x=a} \int_{y=1}^{y=b} \int_{z=1}^{z=c} f(x+y+z) \, dx \, dy \, dz.
\]

Similarly, the condition being that

\[
(\frac{z}{x})^{\frac{1}{a}} + (\frac{y}{x})^{\frac{1}{b}} + (\frac{z}{x})^{\frac{1}{c}}
\]

shall not exceed 1, we have

\[
\int_{x=1}^{x=a} \int_{y=1}^{y=b} \int_{z=1}^{z=c} f(x+y+z) \, dx \, dy \, dz
\]

It is advisable to study the factoring of the integrals and the use of the properties of factorials in the reduction of definite integrals, as the following:

\[
\pi^{\frac{1}{4}} \Gamma(\frac{1}{2}) \Gamma(m+1) \Gamma(\frac{1}{m})
\]

We shall now give some specimens of the results of functions involving trigonometrical quantities. One of the most important of this class is the following:

\[
\int_{x=0}^{x=\infty} \sin nx \, dx = \frac{1}{n} \sin nx.
\]

According as \( b \) is positive or negative.

\[
(\text{a positive}) \int_{x=0}^{x=\infty} \cos nx \, dx = \frac{1}{n} \cos nx.
\]

\[
(\text{b positive}) \int_{x=0}^{x=\infty} \sin nx \, dx = \frac{1}{n} \sin nx.
\]

from these come

\[
\int_{x=0}^{x=\infty} \cos nx \, dx = 0, \quad \int_{x=0}^{x=\infty} \sin nx \, dx = 1.
\]

and from these come two equations which have been much used, long before they were openly expressed, and which exist in the last twenty years.

When \( a \) and \( n \) are both positive

\[
\int_{x=0}^{x=\infty} \cos nx \, dx = \frac{1}{n} \sin nx.
\]

Some difference of opinion exists about these equations, which in fact involve a great deal of what has been done by mathematicians in the last twenty years.

When \( a \) and \( \alpha \) are both positive

\[
\int_{x=0}^{x=\infty} \cos nx \, dx = \frac{1}{n} \sin nx.
\]

This is a specimen of a sort of discontinuity which very frequently occurs, and from not attending to which mistakes have often arisen.

If we call \( \epsilon^{n} \) the hyperbolic cosine and \( \phi \) the hyperbolic sine, and denote them by \( \cosh \) and \( \sinh \), we have, the limits being \( 0 \) and \( \infty \), and \( a \) being less than \( x \),

\[
\int_{x=0}^{x=\infty} \cosh nx \, dx = \frac{1}{n} \sinh nx.
\]

\[
\int_{x=0}^{x=\infty} \sinh nx \, dx = \frac{1}{n} \cosh nx.
\]

\[
\int_{x=0}^{x=\infty} \cosh nx \, dx = \frac{1}{n} \sinh nx.
\]

\[
\int_{x=0}^{x=\infty} \sinh nx \, dx = \frac{1}{n} \cosh nx.
\]

The integral \( 4 \pi \int_{x=0}^{x=\infty} \sin nx \, dx \) is the nth number of Bernoulli (NOMBERS OF BERNULLI, P. C.), meaning that opposite to which \( m \) was written in the article cited.

As specimens of the reduction of definite integrals, the integrals

\[
\int_{x=0}^{x=\infty} \cos nx \, dx \quad \frac{1}{1 + x^2}
\]

are severally equal to

\[
\frac{\sin \phi}{\phi} \int_{x=0}^{x=\infty} e^{-\alpha x} dt \quad [x > a, \alpha > 0]
\]

The following is fundamentally important,

\[
\int_{x=0}^{x=\infty} \cos nx \, dx = \frac{\sin \phi}{\phi} \int_{x=0}^{x=\infty} e^{-\alpha x} dt.
\]

With regard to these equations, it must be observed that they are not to have their algebraical consequences; thus, \( a \neq 0 \), but \( a \neq 0 \). The true meaning of these equations is: as \( x \) becomes infinite, sine becomes insensible, in form, by the angle \( x \) becoming infinite, is properly represented by \( \sin x \) of \( x \).
The integral \( \int \frac{dz}{\log z} \) [0, e] has been tabulated \[\text{[Diff. Calc., L. U. K., p. 662]}\] by Soldner, and a great many integrals may be found from it. Soldner proposes to call it the **Logarithm-integral of \( \alpha \)**, and to denote it by the abbreviation \( \text{li} \). Adopting this notation, we have then, both in definite and indefinite forms,

\[
\int \frac{dz}{\log z} = \text{li}_z.\]

and so on.

Of miscellaneous integrals there is an immense number, of which we give a few instances:

\[
\int (1-x^n)(1-x^{-n}) dx = \frac{1}{n} (1 + x^n) + C.
\]

and other instances.

Further, the equation

\[
\phi(x) = \phi(x) + \frac{1}{\cos \omega} \cos (x \cos \omega) = \frac{1}{\cos \omega} \cos (x \cos \omega) + C
\]

is one which, for all values of \( x \), approaches without limit to truth, as \( k \) is diminished without limit positively. But if instead of the limits \( -\infty \) and \( +\infty \), we write \( a \) and \( b \), a being less than \( b \), then

\[
\phi(x) = \frac{1}{\cos \omega} \cos (x \cos \omega) + C
\]

is a discontinuous function, as follows:—From \( x = -\infty \) to \( x = a \) inclusive, it is nothing: when \( x = a \), it is \( \phi(x) \); from \( x = a \) to \( x = b \) both exclusive, it is \( \phi(x) \); and from \( x = b \) to \( x = \infty \) it is nothing.

The above methods of expanding a function in series of sines and cosines has been extensively used by Le Grange, Poisson, and Fourier. We give it in the most general form after the manner of Poisson. Let

\[
\phi(x) = A_0 + A_1 \cos \frac{x}{\pi} + A_2 \sin \frac{2x}{\pi} + \ldots
\]

and for every value of \( x \) from \( x = 0 \) to \( x = 1 \), both inclusive, this equation is true if

\[
A_0 = \frac{1}{\pi} \int_0^1 \phi(x) dx, \quad A_1 = \frac{2}{\pi} \int_0^1 \cos \frac{2\pi x}{\pi} \phi(x) dx
\]

Again, the equation

\[
\phi(x) = B_1 \sin \frac{x}{\pi} + B_2 \sin \frac{2x}{\pi} + \ldots
\]

is true from \( x = 0 \) to \( x = \pi \), both exclusive, if

\[
B_1 = \frac{2}{\pi} \int_0^\pi \sin \frac{\pi x}{\pi} \phi(x) dx
\]

and further, the equation

\[
\phi(x) = A_0 + A_1 \cos \frac{x}{\pi} + A_2 \cos \frac{2x}{\pi} + \ldots
\]

is for all values of \( x \) from \( x = a \) to \( x = b \), both inclusive, (becoming \( \psi(x) \) when \( x = b \)) if

\[
A_0 = \frac{1}{2\pi} \int_0^\pi \phi(x) dx, \quad A_1 = \frac{1}{2\pi} \int_0^\pi \cos \frac{2\pi x}{\pi} \phi(x) dx
\]

But write \( 2\pi \) instead of \( \pi \), in the limits only, or write \( [0, \pi] \) instead of \( [0, \pi] \) and the equation becomes true for all values of \( x \) from 0 to \( 2\pi \), both inclusive.

Fourthly, we shall give two cases of the method deduced by Cauchy, as specimens: the complete method itself has some difficulties which are not yet overcome.

First, let \( \phi(x) \) be such a function of \( x \) that \( \psi(x + y - 1) \) vanishes when \( x = \infty \) or \( -\infty \) whatever \( y \) may be, and when \( y = 0 \) whatever \( x \) may be. For every root of the form \( a + b/\sqrt{1} \) (\( a \) being either positive or negative, and \( b \) being positive, but both finite) which makes \( \phi(x) \) infinite, let \( (x - a - b/\sqrt{1}) \phi(x) \) be finite; calculate the value of this last product for each root. For every real root \( a \), of \( \phi(x) \) (\( x \) = \( 0 \) not being one) calculate half the value of \( (x - a) \phi(x) \). Let the sum of all these values and half values be \( P \). Then

\[
\phi(x) = \frac{1}{\cos \omega} \cos (x \cos \omega) + C
\]

from \( x = -\infty \) to \( x = +\infty \), and from \( x = 0 \) to \( x = \infty \). Or thus:

The subject of definite integrals is one in which the difficulties, which have always appeared at the boundaries of mathematical knowledge are constantly met with. The consequence is, considerable difference of opinion about many points. On these the student who desires to use the higher parts of analysis must hope to form his opinion independently, when his reading and reflection are sufficient for the purpose. Most of these difficulties belong, in principle, to that which assum-
companies use of divergent series, which is the most important
calculational question now under discussion. If we were to
set out the three fundamental laws of all such series, we
should find that divergent series would one day take their undisputed place among
what is understood about objects of analysis, as negative quanti-
ties and their logarithms, imaginary quantities and their
exponential expressions, fundamental orders of infinity, and
discontinuous solutions of differential equations, &c. They
have successively done, each under a fire of objections which
has well served the progress of science, by the defensive
researches which it has rendered necessary. It is fortunate
for analysis that so many of those who find difficulties propose
the entire rejection of the symbols or methods in which the
difficulties exist: the proposition excites those who are against
any rejection of the symbols, and yields, in their defense and
discrimination, all that their difficulties propose; and if they only had to meet the doubts of allies, instead of the
attacks of opponents. That the symbolic expressions of which
we are speaking, will never vanish out of remembrance
may be inferred from all the points of difficulty of which we have spoken, it may be said, in the words of Horace

*Naturam expellas fera tamquam error*

they will come, and will demand explanation until they get
it. They will conquer by numbers, as Fontenelle said the
symbol of infinity had done. And it is to be hoped and ex-
pected that the difficulty will be completely resolved, with
the appearance of a successor, to excite new efforts, and be
the stimulating cause of further progress. We should be sorry
to think we had arrived at the 'last impossibilities' of pure
mathematics.

**INTERDICT.** In the law of Scotland, supplies the place
of an injunction from a court of equity in England. It is a
prohibitory order, forbidding some act from being done, and
it is obtained on the application of the party who would be
injured by the performance of the act. It may be issued by
the Court of Session, or by the Sheriff’s Court. Interdicts
in the Court of Session are frequently obtained for preventing
informer courts, or courts of limited jurisdiction, such as
the ecclesiastical courts, from exceeding their jurisdiction. To
this end the form was frequently adopted in the late dispute
in the Church of Scotland, which ended in a success. [FAXX
Creaser, P.C.S.] Interdict is applied for by what is called
a ‘Note of Suspension and Interdict’ presented to the Lord
Ordinary on the Bills. In pressing matters, interim in-
derdicts may be granted without hearing, but in the general
case intimation is given to the other party, who gives in
answers. If there are means by which the applicant’s inte-
rests can be kept safe, as by the finding security, or other-
wise, the interdict will not be granted, but the ‘vote will be
passed to try the question,’ and the matter will proceed as an
ordinary litigation.

**INTERMENT.** [INTERMENT, P.C.] Of late years the
subject of interment in large urban places, and a great amount of information has been collected. Though
opinions are not unanimous, the evidence, the further it is ex-
amined, appears to prove that emaciation from crowded burial-
places is a matter of some import in the health of persons
living, or which, indirectly, affects the health of persons
who live near them; and that these emaciations, when sufficiently concentrated may produce
speedy death. The general conclusion that all interments in
large urban places are of an injurious and dangerous tendency’ (Report on the Practice of Interment
in Towns), is at least made a strong probability, and strong
enough, coupled with other reasons, to justify the legislature in
forbidding such interments and all burying-grounds under
such regulations as may prevent the effluvia from the
dead becoming detrimental to the health of the living.
The Report to which reference has been made contains, in
addition to the evidence on the injuries caused by crowded
burial-places, much valuable information on the injury to
health caused, particularly among the poor, by the delay in
interments. The following remark will show the nature and
extent of this evil: In a large proportion of cases in the
metropolis and in some of the manufacturing districts, one
room serves for one family of the labouring classes: it is
there they live, their family, their kitchen, their wash-house, their sitting-
room, their dressing-room, their sitting-room. If they have an
out-door occupation, it is frequently their work-room and their
shop. In this one room they are born, and live, and sleep,
die and amidst the other inmates.’ Among the poor in some

These are the words of Mr. A. V. Vogel, of Leaside, who has recently pub-
lished in this country a work traced to the conclusion of all is not what
published at Leaside, in his own English.
cerebrum of a suitable description ought to be provided and
maintained (as to the material arrangements) under the direc-
tion of officers duly qualified for the care of the public health.
Another is, 'that for the abatement of oppressive charges for funer-
als, marriages, divorces, and services, provision should be made (in conformity to successful cases abroad) by the officers having charge of the national ceme-
teries, for the supply of the requisite materials and services, secure
to all classes, but especially to the poor, the means of refreshment, interment, at reduced and moderate prices, suitable to the state of the deceased and the condition of the survivor.
The numerous matters contained in the Report can only be indicated here. It should be consulted by all who care in the well-being of the country.'

The Law of Nations.

It is clear that thus in its large features, as a rule for the con-
duct of independent communities towards each other, the Law of Nations wants one essential feature of that which is entitled to the term law—a binding authority, and that the provisions even in the most powerful states are not without exception a
raising hostile combinations and otherwise; but there can be no uniformity in these checks; and in general when the
interest is of overwhelming importance, and the nation powerful, it takes its own way. The importance of the questions which
may be involved in the Law of Nations thus materially affects the question how far it is uniformly obeyed. In a set of
minor questions—such as the safety of the persons of ambas-
dadors, and their exemption from responsibility to the laws of
the country to which they are accredited, and in other matters of personal etiquette, a set of uniform rules has been estab-
lished by the practice, under the influence of a common
reasoning.

INTERNATIONAL LAW.

This term was originally applied by Bentham to what was previously called the 'law of nations,' and it has been generally received as a more apt designation than that which it superseded. When the term 'law of nations' was in use, that of law of nature did not in the
view of international law, and was sometimes employed as a synonym, and as indicative of the boundaries of the subject. It was thus in its proper
sense restricted to the disputes which governments might have
occasion to settle, and did not in the view of the subject matter
involving differences of subjects, arising out of the
position of the states with regard to each other, or out of the
internal laws of the separate states. But under the
term 'law of nations,' the whole of these subjects, intimately connected with each other as they will be found to be, can be comprehended and examined, and thus several important distinctions and exclu-
sions are avoided. Many of these subjects are interwoven,
the following instances may be taken:—A part is put in
state of blockade; a vessel of war of a neutral power breaks
the blockade: this is distinctly a question between nations, to be
settled in the court of international law, and for the law of peace,
there are any consensual rules on the subject, and the
parties will submit to them. But suppose a merchant vesselelonging to a subject of a neutral power attempts an infringe-
ment of the blockade, and is seized:—here there is no question
between nations in the first place. The matter is adjudicated
on in the country which has made the seizure, as absolutely
and unconditionally as if it were a question of internal smug-
gling; and it will depend on the extent to which it may result in
the judicature of that country, and not on any question settled
between contending powers, whether any respect will be
given to the bill of rights or not; and in the ground of
the sovereignty of the nation, or otherwise. But there is
a third class of cases most intimately linked with these latter,
but which are completely independent of any treaties,
declarations, or other acts of sovereignty, which may
have been entered into or committed by nation to nation.
They arise entirely out of the internal laws of the respective
countries of the world, in as far as they differ from each other.
The 'conflict of laws' is a term very generally applied to
this branch of international law, and the circumstances in which
it comes into operation are when the judicial settlement of
the question takes place in one country, but some of the circum-
cstances of which cognizance had to be taken have occurred
in some other country where the law applicable to the matter is
different. One of the most common illustrations of this subject
is,—a judicial inquiry in England whether a marriage has
been taken place in Scotland according to the law of that country;
or a habeas corpus case in Scotland, whether the child has
been taken away from its mother according to the law of England; in either of which cases there
will generally be the further and nicer question, Which
country's law ought to prevail as the criterion?
The three leading departments of international law are:

1. The principles that should regulate the conduct of states to each other.

2. In use, the rules that should regulate the rights and oblig-
ations of private parties, arising out of the conduct of states
to each other.

3. The principles that should regulate the rights and oblig-
ations of private parties, whose acts are affected by the separ-
ate internal codes of distinct nations.

The first of these has been the principal subject of the
well-known works of Grotius, Puffendorf, Vattel, and other
publicists, who have derived from general principles of
morality and justice a series of minute abstract rules for the
conduct of nations towards each other, and subsidiarily for the
conduct of their subjects in relation to international questions.

It has been usual to call this department the 'Law of Nature,'
and an attempt has been made to reduce and moderate the
principle of its influence, though it has not the support of the authority of any legisla-
tion, it is founded on the universal principles of natural
justice.

It is clear that thus in its large features, as a rule for the con-
duct of independent communities towards each other, the
Law of Nations wants one essential feature of that which is entitled to the term law—a binding authority, and that the provisions even in the most powerful states are not without exception a
raising hostile combinations and otherwise; but there can be no uniformity in these checks; and in general when the
interest is of overwhelming importance, and the nation powerful, it takes its own way. The importance of the questions which
may be involved in the Law of Nations thus materially affects the question how far it is uniformly obeyed. In a set of
minor questions—such as the safety of the persons of ambas-
dadors, and their exemption from responsibility to the laws of
the country to which they are accredited, and in other matters of personal etiquette, a set of uniform rules has been estab-
lished by the practice, under the influence of a common
reasoning.

The Combinations for the preservation of what is called
the Balance of Power [Balance of Power, P. C.] are among the most useful restrictions of ambition. All periods of
history furnish illustrations of this principle. Hume found
that the Peloponnesian war was carried on for the preservation
of the balance of power against Athens. The late war exhibited
a noted illustration of combination to prevent universal con-
quest on the part of the French. The safety of small states
from being absorbed by their larger neighbours, is in the
jealousy and friendship of the smaller states an aggran-
disment. Thus the balance of regulations is one barrier to
injustice. Another is public opinion; sometimes that of the
nation whose rulers would be prepared to commit injustice—
and public opinion, for the same reason, is far less likely to
be made a mere abstraction or a sentiment, than public
opinion, and is an accessory to a very limited extent that the public feeling of a despotic
injustices, the grasping spirit of its rulers; but the
public feeling of the constitutional and democratic states
is the great check on the injustice that might be perpetuated
by a nation when it becomes so powerful as Great Britain.

The seizure of the Danish fleet by the English has been a
subject of warm censure in this country. Necessity—even
the plan that Napoleon would have used the fleet to invade
our own shores—has not been accepted in palliation of the
act; and the manner in which it has been canvassed is very
likely to prevent any British government from adopting the
precedent. The act of France has taken place under a
injustice condemned by the public feeling of countries other
than those by which it was perpetrated; and it may be ques-
tioned whether the states which accomplished the partition
may not be considered, not by the French, but by the
nations like respectability in private circles, a source of
power through external support; and the conduct of Russia
and Poland has generally diverted from the former
the name of freedom of nations has been observed that the press, whether fugitive or permanent, is the
most powerful organ of this public opinion, and that the views of
able historians, jurists, and moralists, have much influence in the
progress of international law. The principal
subject of dispute in this department of international
law are—the sovereignty of territory and the proper con-
duct of states, as in the question at present under debate re-
guarding the Oregon territory in North America; questions as to discovery and first occupancy of barbarous countries; questions as to the conduct of neutrals in wars between states. In all these cases the courts have been called on to decide whether the conduct of nations towards each other, as their national honor may require, was not justified by the law of nations. In other cases the courts have been required to decide whether a case was one in which the law of nations could be applied to the conduct of nations towards each other, as their national honor may require, on a question of commercial law.

The third division of international law is that which most properly comes under the head of "Conflict of Laws," viz., the principles that should regulate the rights and obligations of private parties when they are affected by the separate internal codes of distinct nations. This has some points in common with the preceding department of the subject. It involves private rights, and, at the same time, questions of international rights; and the adjustment of each question depends on the laws of the country to which the parties, or the issues between the parties, belong. However, it is a distinct department of the subject, and its right to be regretted that the questions so far as they are not yet in a state of ready to be subsequently settled by the negotiations of 1818 upon the equitable footing of regular authentic lists or registers of British and American seamen being made up and kept, and of the nationality of the seamen being thereby determined.

INT

this principle, treaties were lately made with France and the United States for the purpose of settling the dispute between these countries. Two acts of parliament were passed (6 & 7 Vict. c. 75 and c. 76), by which a secretary of state, on the requisition of the ambassador or other representative of France or the United States, was enabled to make an order to seize a person accused of a crime, a magistrate being enjoined to put in force on his being satisfied that the charge is such a nature as would authorize him to commit a person charged with the same, or with the like infinite of the laws in their own jurisdiction. Consequently, Treaties, P. C. S.] But it has been a rule in many countries, and particularly in our own, that no aid is to be given for the enforcement of the political laws of foreign states. As in other branches of civil law, our enactment and in many countries slavery comes to be a question of property, but with us it can only be a question of government; and we cannot view any rules regarding property in slaves as relating to private rights, an infringement of which, when held to be criminal in the slave-holding country, must be so also here. Accordingly, in the celebrated case of the Quoile, in November, 1841, when certain American slaves escaped and found protection in a British settlement, it was found that we could not send them back to their owners as robbers who had with violent ingredients their own persons from the custody of their proprietors. As on the one hand the criminal law is that to which this department of international law most broadly and distinctly applies, and on the other hand the position of property is that to which it has generally the least reference. The reasons of this distinction are very obvious: his own personal conduct is that object of the law which a man most completely and absolutely controls; from one country to another, his connection with landed property is the relation in which a tribunal out of the country in which the property is, has the least chance of adjudicating. Between these extremes there are many questions regarding persons in their relations to each other, and regarding contracts as to movable or personal property. It came thus to be a general principle, that rights connected with landed property must always be settled by the laws of the country in which the land lies, while the question regarding other property might be subjected to other criteria of jurisdiction. Perhaps historical circumstances in the early history of the European nations favored this division. The various tribes which occupied the territory of the Roman empire appear to have carried with them their own peculiar laws and customs. Saviugy quotes a letter from Bishop Agobardus, in which he says it often happens that five men, each under a different law, may be found walking or sitting together—a state of society at this day exemplified in some oriental nations. Among all these distinct tribes the feudal system arose as the general and uniform territorial law. Through a series of circumstances the feudal law has been here. The Roman law became the rule principle as to persons in their relation to each other when that relation was not of a feudal character, and as to claims regarding movable goods. The common law and civil law has perforce been affiliated with the other European codes. But it has fortunately happened that those departments of the law with which international law is chiefly concerned—the constitutional and the admiralty law, have been considered as the legitimate offspring of the civil law, and have adopted in a great measure its principles as they have been in practice throughout Europe. The mercantile law in England has accommodated itself to the custom of merchants; and this custom has in a great measure arisen out of the adaptation to modern commerce of the principles of the civil law. The portion of the commercial code of England which is least in harmony with that of other countries is perhaps the bankruptcy law, which, being statutory, has not so pliantly adapted itself to the exigencies of foreign commerce as the consuetudinary portions of the commercial law have done. Thus, under the old sequestration or bankruptcy statute of Scotland, which was supposed to give the trustee or assignee full power for obtaining possession of the bankrupt's property in all parts of the world, it was found that, for the reason of action for a debt owed in England—the right of the trustee being that of an assignee merely, and a right to a debt being a chose in action, and therefore not capable of being assigned by the law of England, Section 16 of the Bankruptcy Act, 1869, to a bankrupt in England the law of bankruptcy appears to be one of the most difficult of adjustment to international principles. There are clauses in the bankruptcy and insolvency acts of England by which, through registration of the vesting order, the assignee becomes entitled to all real or personal property,
ments were compounded in the laboratory by its inventor. But it is not the accident, no matter what but a discovery: we should recommend them to draw the distinction, as useful to the memory in relation to the his-
tory of their science.

The words discovery and invention a tempting resemblance, often just, and often fallacious, to those of theory and practice. But in fact each of the things must be subdivided into theoretical and practical. The effect of the non-spherical atom of the earth. The moon's motion was discovered theoretically: the variation and the ejection were discovered practically. As to inventions, we call Davy's safety lamp a theoretical invention: for the question given was how to make a lamp; and he was not even assumed that a lamp was to be constructed. But the common story of the boy who saved his labour by tying a string from the valve he was employed to open and shut to a part of the machinery which moved in such a manner as to do it for him, is, if true, a record of a practical invention.

Still there is truth in this, that practical men, properly so called [Theory and Practice, P. C.], have invented oftener than they have discovered: and that theoretical men have discovered more often than they have invented.

It is no wonder that the early history of discovery should be confused and uncertain: the loss of documents which op-
rates on all our first knowledge of antiquity, is a sufficient ex-
planation. Nor is it surprising that first writers should be persons of unsettled claims; that in the case of Euclid, for example, no claimant had ever heard of his discov-
eries began as where they ended. But it does seem strange that in matters of our own day, or that immediately preceding, it should be a question to whom a right of discov-
ery belongs. But when we come to an actual look, to the date of the publication of which there is every possible attestation.

There is one important preliminary consideration, which will, in the minds of those who for the first time give it due attention, change the face of the whole question. When the period arrives at which a discovery becomes possible, there are many courses which lead to it, and many ships sail on the waveless sea towards the distant land. In the case of Davy's lamp, it is interesting to see how the wave rippled further. When a new island is discovered in or near a fre-
quented track, as soon as a ship of one country casts anchor in a port and takes possession, it may be afterwards found in some logs that something like land had been sus-
ppected before, in others that land birds had been seen, in others that the colour of the water was noted, in others that an alteration of the current was observed, and so on, all near the same point, and any one of which might have led to the dis-
coveries, if the hint had been followed. It is the same in matters of science, to an extent which will not be easily credited by those who are not acquainted with its history. And this greatly enhances the merit of the most original researches, and does much to the credit of Newton that Huyghens had gone as far as to determine the conditions of circular motion, that Grimaldi had observed, and that Cavendish had measured the specific gravity of the air. That Cavalieri had all but discovered the method of fluxions. The character of accidental good fortune disappears when we see that the progress of knowledge seems to bring new results within the possible reach of many, but within the actual grasp only of one. Is there then nothing accidental in dis-
covcry and invention? We answer that there is something, but that the accidents which might produce discovery are happening to all, and frequently; while the accidents which do produce it happen to those only who are ready to take advantage of them. But this it may be said is reasoning in a circle; for if we are asked how we distinguish the person who is ready to take advantage of the one who is not, we have only the dis-
coveries to point to. We reply, that it generally happens that the persons who can thus fix a cavoury, are also those who give evidence of successful research in cases where fortune shows no special favour. It was by a mere accident that Mr. Baily [Flamsteed, P. C.; Bailey, P. C. S.] bought a house oppo-
site to the possession of a large hundre of Flamsteed's letters, and the fact that his existence came to his ears. Many people perhaps had seen them—indeed, it is not for-
granted that the contents were all in print, or been unable to judge of their value. But the life of Flamsteed is not the only one of such events. As the phenomenon of the same history: there was no accident about the editorship of the old cat-
alogues. It is said to have been by a casual effect of the sun-light at a window that Malus discovered the polarisation of reflected light; but then Malus was a profound optical in-
vestigator. It is our conviction that no accidents are value less except those which happen to the person who is right in
times; and that there are usually other means of showing this besides the success of the accidents themselves.

Before we can examine the title to a discovery, it must first be settled what is a discovery: and the greatest difficulty. The case of the steam-engine is con-
tantly under discussion; and the principal point at issue is, what is the steam-engine. Heron of Alexandria certainly produced a rotatory motion by steam, and it is sufficiently clear that he could have ground all the corn in Egypt by his method. If we assign the merit to the person who contrived such an economy of fuel as to place the use of steam on something like a footing with that of water, we must also decide whether any except Watt has the claim. Mr. Arago remarks on this subject, that a watchmaker would be struck dumb by the question, who invented a watch? The thing as it now exists is not the invention of any one person. As long as there is any national feeling in the discussion, one or another definition will be proposed, constructed to suit the advocacy of one or another claim. We have not here to settle the cases which we once; it is enough that they illustrate our point.

It may happen that in a complicated instrument or method, the perfecting of which extends over a long period, there is some one distinguishing characteristic the introduction of which marks the main epoch of the invention. In the case of the watch, for instance, if we ask for the distinctive definition of the watch, and that it is a mechanical instrument for measuring time, which would include the clepsydra, nor an application of wheel-work for that purpose, which would in-
clude the clock; but it is the use of a spring for the regu-
lator, in which we have the distinction of Watt. The next question is, did Watt observe it? or does it stem from other horologes. In a similar manner we look upon the ad-
misions made by Vieta to the mechanism of algebra as consti-
tuting the main groundwork of what now bears the name. But it would be exceedingly wrong to say that Hooke invented a watch, or that Vieta invented algebra: things done before and after both essentially belong to the ideas we mean to convey by the words. But it is not an uncommon practice of writers to strip a word of its ancient eras and carry it further. It does not seem enough perhaps) the invention so cut down to some one person, and then to clothe the word with all its most modern associations, and the favoured inventor with all the glory which ought to be divided among many. When the steam-
engine is reduced to a tesseract, or at most to a pump, it is Avery, or De Claus, or Worcester, or Newcomen, or 
Japin, &c. &c. who invented it, according to the country or the fancy of the writer; but when once the claim is established, the tesseract throws out a condenser, and the pump runs along the railroad at sixty miles an hour.

The common law of science requires that the applicant for a patent should make a distinct specification, not merely of what he intends to construct, but of that particular part of the contrivance which he claims as his own; and here a claim is made to an idea, or to the discovery of an application of the patent. [Patent, P. C.] The cases which have occurred under this law would be good study for those who write on discovery.

It may indeed happen that the amount of claim may be materially augmented by the view which the discoverer takes of his title. Columbus inferred, on true principles, the possi-
bility of crossing the Atlantic, spent the energies of a life in pro-
curing the means of making a trial, and is therefore pro-
perly and truly the discoverer of all the new world: the
Northmen who had visited it long before did not promulgate their discovery, and it might as well be given to the slorinated inhabitants of the coast that it is to us. It does not de-
preciate the merit of Columbus that he could not but suppose he should reach India or China: these were the certainties at which he aimed, and which he would have reached had he not been stopped by the intermediate continent which ought to bear his name. Had Heron, when he first announced and executed his revolving boiler, been able to point out that it was a method of producing force by an apparatus which might supply the demand for a more human labour—that all which remained was adaptation—and that skill in the use of this new kind of force would make it a substitute for the strength of men and beasts, there is no reason why we should not give him the title of the discoverer of the steam-engine, and the in-
ventor of the first step. Among the consequences of attempting to describe discoveries under too general terms, is this, that both things and persons are allowed to clash unnecessarily.
It is not always, to be sure, that this pears such a length as procuring for Dalton’s atomic theory the character of being a republication of the notions adopted by Epicurus from his predecessors; if it did there would be the less harm: there are many theories between which mischievous confusion is more easily perpetuated than those of the philosophers of Athens and of Manchester. The nomenclature of science is perplexed by phrases of non-precision—as that Newton discovered gravitation, instead of a true explanation of the heavenly motions by means of gravitation—yet the first advanced the true theory of astronomy, which he did in one sense, and Copernicus in another; whence the provinces of the two are frequently confused. It must also be noticed that a mere opinion does not result of choice between one or other of which must have been taken, is confounded with the same opinion advanced and supported by reasons. Thus Philolaus and Aristarchus ascertained the motion of the earth, and Copernicus is said to have only revived their opinion. The difference between the two cases lies in this, that the antient philosophers merely asserted their belief, the modern one made his hypothesis the means of accounting for all the known motions of the heavens, diurnal, annual, and precessional.

The specification, to borrow a term, having been agreed upon, the next question is, what constitutes a claim to discovery? This is a priority of publication to me, as often happened, two persons should discover the same thing about the same time, the one who first publishes is universally recognised as the discoverer. Of course, if a fraud can be shown, to be satisfactorily done, i.e. that the first publisher stole his matter from another, he would not be allowed the advantage of his wrong: but the onus of proving the fraud lies entirely upon the asserter of it, and, until the evidence and the trial of the case, the priority of publication.

The reasons for this rule are not altogether those which exist for the rule in law. The objects of the latter are the protection of private rights and public peace; or rather the assignment of private rights in such a manner, as, in the long run, to promote the welfare of the community, and particularly its peace, without any great shock to the natural feelings of equity. It is not difficult to conceive a case in which men would be more easily satisfied with a small per cent difference between the just and the fraudulent, than a small per cent of punishment for a crime of this magnitude.

This rule, that first publication gives the right, until the contrary is proved, is adopted for the sake of its own probability, as a starting point. Selves, at hazard, the name of a result, and of its first announce; no doubt will exist in the mind of any one, used to the history of science, that it is at least fifty to one the name of the real discoverer is thus given. But if it be that the discovery was made too late, and, for that reason, if that fact can be established, the history of the human mind must not be falsified by adherence to a rule. If, for example, it could be made out, from internal evidence, that Archimedes must have known the principle of the lever and a difference of deference to the notions of his time prevented him from publishing, it would never do to let the formal claims of Leibniz and Newton prevent the allowance of that of Archimedes: for then would result the suppression of the actual fact, which, if true, would be of great consequence, namely, that the Greek mathematicians were powerful enough to lead their best minds to the discoveries of modern times. We insist upon this because we have observed a considerable tendency in writers of history to establish a rule on legal grounds of peace and convenience. There is also a confusion between two distinct things; the claiming of priority, and the claiming of the facts. The former demands true facts, the latter just appreciations of his merit. By a perversity of the human mind, Newton and Leibniz would lose fame to-morrow, more or less,—that is, more with some and less with other people, than if Archimedes had been left to turn up, showing that he possessed a formal differential calculus. We are apt to assign praise to mere priority, independently of originality, and to withdraw it on failure of proof. Priority is nothing, and the claim of the individual: the former demands true facts, the latter just appreciation of his merit. The same principle applies in this, that the earlier an invention or discovery is made the nearer are the methods and instruments, and the fewer the hints to which it is due. For example, D’Alembert re-invented a method of analysis [Pacioli in Opera, p. 192] in the year 1754, which he hand to the French Institute within a few weeks of each other, the pre-
IN V

presumption must be rebuffed by any one who desires to prove plagiarism. But as the observation becomes greater, the presumption, for as it is derived from time only, is weakened. In such a case, the internal evidence of the writings themselves must be carefully looked at. There is some difficulty in the nature of the subject in which different investigators arrive at, and even in which they state, the same conclusions: those who would do a dishonest thing might know this as well as others, and might endeavour to counterfeit it perfectly originally. To detect this base metal is not always easy: to prove its baseness is next to impossible. But it mostly happens that really independent investigators carry their results to different lengths; one will go further in one part than another.

As may be supposed, the most disputed cases are national ones; including in that term the schisms of different classes in the same country, as the scientific feuds of universities, of literary societies, &c. And between people of different countries and governments, the question arises in two distinct ways, not only as to the definition of the discovery itself, and the priority of publication, but as to the country to which the discoverer is to be said to belong. And here there seems to us to be a necessity for a distinction which is rarely made, and no wonder; national pride is the mortal enemy of discriminative argument. All people like to believe that their race is gifted by nature with talent, and that their public policy is calculated to draw it out. For proof of this they appeal to their great writers and thinkers, among whom they include all whom they have driven into their country, and all whom they have driven out. Many eminent men who have been induced to settle in a country not their own, may be a credit to the institutions, but can be none to the race, of their adopted country: while those who are driven away do honour to the race, not to the institutions of the land from which they are exiled.

Take the cases for instance of Lagrange and De Moivre. Lagrange, who, of many offers made to him when he left Prussia, preferred to go to the kingdom of France, resident there from 1787 till his death in 1813, was exempted from the expulsion of foreigners ordered by Robespierre, and received, during all governments from the old monarchy to the empire, every possible honour and aid,—is a greater credit to French institutions and feelings than if he had been born in their country. But as far as blood is concerned, he is almost wholly Italian, having been born, and established his first reputation, at Turin: it is said, we do not know on what authority, that his great grandfather was a Frenchman, which may entitle France to claim the eighth part of him. De Moivre, on the other hand, born of French parents and educated in France, was driven from his country by religious fanaticism, and none of his works were published either in France or in French. Whatever credit his talents may do to his race, he is but a foreigner in the institutions, as to which he never lived. Not that he received such encouragement here as would entitle us to say that the honour lost by France was wholly gained by England. While picking up a scanty livelihood, perhaps, by only walking, or writing, he could find time to read the Principia was by tearing it leaf by leaf, and carrying a leaf in his pocket to look at while walking from one pupil to another, or at any other chance interval.

There is much absurdity in the mode by which national processes in matters of discovery is tested. A few of the very first names are made the only subjects of comparison. There is some presumption, certainly, that the great names are best of many, and that the plants most abroad where the largest plants are found. But this presumption must not be urged when an attentive consideration will settle the question. *We take this opportunity to correct an insinuation against a statement made by Newton, which appeared in a letter to the editors of the Royal Society, as cited by Dr. Thomson and Sir David Brewster, the committee appointed to report on the dispute about the invention of fluxions consisted of Aristotle, Hill, Halley, Jones, and Machin, Burnet. This, we said, was very unjust, and brought in the names of different nationalities. We could thus suppose that the list in the Royal Society's own records was incorrect: nor that it could be supposed that Newton's name is inserted to discover an error. But in the life of De Moivre, written by 'Mr. Mary,' as he calls himself, but who must have known the vituperations of envy, of faction, of autobiography, and of the friend of De Moivre, we find it stated that the committee consisted of Aristotle, Hill, Halley, Jones, and Machin, Burnet. The life of De Moivre, written by the learned author of the life of David Hume, Roett (the principal Motteur), De Moivre, Aston, and Taylor (the learned editor of the Royal Society's Transactions) says that the Royal Society's statement is correct, and that the first five names were subsequently added. Newton was therefore justly incurring the consequences of his conduct, though the neglect of those who sought to have ascertained all the minutes which intervene between the first appointment of the committee and the report. That Newton has made his assertions of being the discoverer, and as such, is a subject of which he must have known the truth.*

without it. Archemedes was the greatest of the Greek mathematicians; but his fame is but little reflected in science of all the countries in which Greece had colonised. So far from it, that when in the sixteenth century, Maurolico lived and wrote, the following epigram was made upon him—

\[ \text{To gouge Zanella tint, Maurolico, se sit in uno Clara Syncrolo shea are on.} \]

The most difficult question of all is undoubtedly what degree of merit belongs to a discovery, and the settlement of the question where in the list it places its author. The public in general judges with utility; whereas it is notorious that many discoveries show more power of mind than others of much greater value to the world. The rule of utility is a good one for mankind in general; but it must be taken with modification by the historian of science. Who has most benefited his species, and who has shown himself most above all his species in intellect, are two different questions. The merit of the inventor, and his genius, are not comparable quantities. The former is determined by the study, the personal skill or inclemence which it was requisite to undergo, the patience and perseverance which must have been shown, and the goodness of the motive which appears to have attended it. The latter is the greater the less the pain and labour, and the wholly independent of moral considerations. A patient schoolboy who multiplies one number another with time and care, will have more merit than a wonderful youth who has appeared, and who can do it in their heads; but the first has far less mental power, in this one line, than the second. All these things are plain on the first statement; but they are far from receiving the same attention, and will so remain until the history of discovery is written without too much deference to popular reputation.

We may mention, as a thing to be guarded against, the disposition to depreciate a discovery because it is not something more than it pretends to be, which is frequently combined with a wish to judge of its merit by an arbitrary *a priori* standard of what it ought to have been. Sturm's theorem is a very pretty instance. Before it appeared, a purely theoretical and strictly certain method was eagerly sought after, and any such, however difficult, would have been held a great gain. The object is at last attained, but in a manner which is troublesome to use. To look at the way in which some writers now mention it, one would suppose they had entirely forgotten how many investigators of the first order had given up the subject without producing any method at all. INVESTITURE. [FREDA SWEERT, P. C.]

INVOLUTION AND EVOLUTION. In our article under this head, we gave an account, with instances, of the method of solving equations, which is commonly known by the name of the *Method of Computation, P. C. S.* is one of the best exercises in computation; and secondly, because of its meaning, and is generally understood, and the latter is very instructive. We suppose the reader of this article familiar with the one which preceded it.

The process of *involution,* as defined in the article cited, is the formation of the value of a rational and integral algebraical expression, such as \( (ax + b)^n \), by a succession of multiplications separated by additions, as in

\[ \{ (ax + b) (ax + b) + \} + \]
We first put down the coefficients as usual, not changing the order of the columns (which is only a matter of convenience, and does not alter any figure). The value of x being 121-23, we begin with 100, which, having two ciphers, we mark off by commas from the several coefficients 0, 3, 4, 6 places. We then proceed with Horner's process with the figure 1 (not 100), taking care to make commas fall under commas, or to use the commas as if they were decimal points (which they are in fact, though not unit-points). As soon as we have done the first 121-23, we go on in all that comes before the lines A, we learn as follows. Let 
\[ \frac{1}{2}x = 9z^2 - 3144x + 9000 \]
then, x being 100, \( \frac{1}{2}x, \frac{1}{2}z, \frac{1}{4}z^2, \frac{1}{4}x^2 \text{ and } \frac{1}{4}x^3 \) are severally 987176-301, 200971-609, 2669-850, and 9. We then write down the results again, after the lines A (which is not necessary in calculation), merely to show the new disposition of the commas. We are now to proceed with 20 (from the first 2 in 121-23), which, having one cipher, we mark off 0, 1, 2, 3 places in the several columns. Immediately before the lines B we learn that when \( x = 120, \frac{1}{2}x, \frac{1}{4}z, \text{ and } \frac{1}{4}x^2 \) are severally 150503481-181, 388046-169, and 3236-695. We then write down these results without any commas, and proceed with the second 1 in 121, from which we find that when \( x = 121 \), the functions are 15896563-209, 39456-867, and 3269-659. We then begin to provide for the decimal point, by annexing one, two, and three ciphers to the working columns, and taking the second 2 in 121-23 work with, and applying Horner's process, we find, when \( x = 121.2 \), that \( \frac{1}{2}x, \frac{1}{4}z, \frac{1}{4}x^2, \text{ and } \frac{1}{4}x^3 \) are severally (remembering that all the annexed ciphers are so many additional decimal places) 15079257-2176, 395835-51060, and 3269-5260. Finally, we annex the ciphers with the 2 and we find that \( x = 121.2 \) gives 15087533-760954100, 396049-8064400, and 3269-096000.

Let us now compare the trouble of this process with that of any other method of doing the same. If we throw out all the figures which we have written twice over merely for explanation, and also the last two and one lines in the second and third columns, which are only wanted to go on farther with, we have written down about 280 figures. The ordinary verification costs about 340 figures. It is true that every step is both a multiplication and an addition in one; but this can be done and ought to be done in the use of the second method, and is not done in the ordinary method. And we have not only the advantage of a purely mechanical method, in which the first arrangement causes the succeeding steps to require nothing except a look at the successive figures of the value, but the still greater advantage of being able, at the end of the process, to make any small alteration of value with ease. If, for instance, having discovered that 121-297 would do better than 121-23, we wish to get additional accuracy, we have but to rub out the last 3-process, and proceed with 9 and 7. In the ordinary mode, we must either repeat the whole process again, or correct approximately by substituting 121-23 - 008, which will require us to calculate \( \frac{1}{2}x^2 \), and perhaps also \( \frac{1}{4}x^3 \).

We will now exhibit a common multiplication, and the formation of a square: not, of course, that we attach any particular value to these simple cases, but that we may show the uniformity of the process. Required 14796 \( x^2 \) or the value of 14796 \( x + 0 \) when \( x = 32316 \). We repeat the lines as before, but not than is necessary, and makes this process look very long.

\[
14796 \quad 0.0000(32316)
\]

\[
443898.0000
443898.0000
473472.0000
473472.0000
4779108.0000
4779108.0000
47805870.0000
47805870.0000
478147536
478147536

Required the square of 279-46, or the value of \( x^2 + 0x + 0 \), when \( x = 279-46 \).
To what is said in *Involution and Evolution*, P. C., we may add the following remarks:—1. When the last term is positive, and would in the ordinary process be made negative, it is better, instead of changing the sign of the last coefficient only, to change the sign of all but the last. Thus in solving $a^2-11a+1=0$, the heads of the columns should be $-1, 0, 1,$ and $1,$ instead of $1, 0, -1,$ and $-1.$ Also, that if at any period of the process the divisor and dividend columns should become negative, the signs of all should be immediately changed.

2. In making the contractions, it will be advisable to make the figure which comes next after the separating line correct, to continue it, in fact, till the next contraction, and to use it to carry from, till it be not used in our main article (P. C.), but it is done in the instance in *Computation*, P. C. S., that in that instance, the following figures, seen one over the other in the last column but one, as follows $3, 5, -6, 9, 1,$ $-2, 3, 2,$ are figures cut off by the contraction, but made up from the second column to carry from into the fourth.

3. If, at the beginning of the process, all the heads of the columns be multiplied by 9, the root will not be altered, and, until the continuation begins, the verification by casting out nines is rendered easy, since every result in every column is divisible by 9.

We shall now show how the process works in some equations which have equal, and nearly equal, roots.

Let $z^2+6z+9=0$, which has two roots, each equal to $\sqrt{3}$.

The existence of equal roots, or of nearly equal roots, might be here suspected from the slow increase of the divisor column; but the method could not verify the fact of their being two absolutely equal roots. The column preceding the divisor column being large and negative, requires us to make trial of figures above, not below, those which the divisor column seems to indicate. But nearly equal roots may sometimes be detected, as in the following instance. Let $7z^2-10z^3-14z+20z=0$, of which it is known that one root lies between 1 and 2. The ordinary process gives

This root may be carried on without difficulty. But at the end of the second process, when the dividend is reduced to 8000, the divisor only 8000, and the preceding column as much as $-1940$, it may be worth while to try another figure.

This state of things gives a suspicion that there is another root in the immediate vicinity of the one in hand. If the three last columns be $a, b,$ and $c,$ and if we find that $pa-b$ is nearly $c-p$, which is the trial test of $p$ being a new figure of the root, we are sure that $(p+1) a-b$ will not be near $c+(p+1)$; and moreover $p(p+1)b-c$ has not two positive roots. The three last columns are $-a, b,$ and $c,$ and may very easily happen that $-pa = b,$ nearly $c-pq,$ and $b-pa = b,$ nearly $c+q$; for $(b-pa)=c$ has two positive roots. Perfect certainty, in the absence of an easy algebraical criterion, may be obtained by trying every figure. In the instance before us, finding $1-41$ succeed, with a presumption of a larger root, we try 1-43, beginning with $-7$ and $1940, 8400, 8000$...

There is now a difference of sign between the two last columns, but, looking at the second column, we see that agreement may be restored by the next figure. The figure 8 will do it, as follows:

<table>
<thead>
<tr>
<th>-7</th>
<th>1940</th>
<th>55600</th>
<th>-94800</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1968</td>
<td>-103408</td>
<td>-156726</td>
<td></td>
</tr>
<tr>
<td>-19636</td>
<td>-262864</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

and $26286400$ is not contain 10 times in $156726000$. All the signs being now negative, we may change them all. If we had tried 7 instead of 8, we should have had

<table>
<thead>
<tr>
<th>-7</th>
<th>196800</th>
<th>55600</th>
<th>-94800</th>
</tr>
</thead>
<tbody>
<tr>
<td>-196900</td>

<td>-396919</td>
<td></td>
</tr>
<tr>
<td>-191800</td>
<td>-222999</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

But now 29920000 is contained more than 10 times in 399619000, which shows that 7 is not high enough. If we try 9, we have

<table>
<thead>
<tr>
<th>-7</th>
<th>19800</th>
<th>55600</th>
<th>-94800</th>
</tr>
</thead>
<tbody>
<tr>
<td>-198000</td>
<td>-129547</td>
<td>1-39199</td>
<td></td>
</tr>
</tbody>
</table>

and a permanent difference of sign is established between the two last columns, whence 9 is too high. Proceed then with $1998800$ and $26286400$ ... for a root. The reader may watch the operation in the following equation:

$9a^2-66a+73=0$

the roots of which are $1-111$, $1-299$, and $1-238$...

Whatever common figures two roots of $a^2=0$ may have begun with, there must be a root of $\phi=0$ which begins with these figures. And whatever common figures three roots may begin with, there must be two roots of $\phi=0$, and one root of $\phi=0$ which begin with those figures: and so on. If there were a difficult equation having three roots nearly equal, no method of detecting them would be easier, of all those known at present, than solving contemporaneously the three equations $\phi a=0, \phi a=r, \phi a=0$, not making any step in one till all had been brought up; that is, one step of each first, then the second of each, and so on.

It may happen that a finite root is established, and yet that the process must be continued to obtain another root beginning with the same figures. For example,

$9a^2-66a+73=0$

It will be seen in the following process that 2 is a root, with a presumption, by the appearance of the divisor column and the one before it, that there is another root beginning with 2. And by trial 2-1111 is found to succeed.

We shall now proceed to a more account of the history of this problem, and of the controversies which have existed, and to some extent still exist. For a fuller account of it up to the time of Mr. Horner, see an article in the 'Companion to the Almanac' for 1839.

Before the time of Viet\ud322, resolution consisted in the rules for the performance of division, and extraction of the square and cube roots, in forms probably derived from the East. To him (VIET\ud322, P. C., p. 315) we owe the first publication of a numerical method of finding the successive figures of the root of an algebraical equation by means of the value of the function equal to zero in the equation. This method of Viet\ud322 is in fact that which Horner’s process now makes so easily practicable. If there be the equation, and a part of the root, it uses $\phi a$, and $\phi (a+1)-\phi a$ as a divisor. The process is so cumbersome, that Viet\ud322 does not attempt to apply it to equations having more than two figures in the root.

This method attracted but little attention on the continent;
but in England, where everything relating to numerical calculation has been always diligently studied, it was much noticed, and received extensions of power. In the posthumous work (1631) of Harriot (Liber Tertius, P. C.) examples of it are given with the improvements of certain figures of the divisors as were wanted; and he ventured upon roots of three places. In the second edition of Oughtred's 'Clavis Mathematicae' (1667) Vieta's method is given without Harriot's improvements. It did not find itself among the first who used Vieta's method to any great extent was Briggs, in the calculation of the sines, &c., in the 'Trigonometria Britannica.' In the preface the method is applied to equations of the third and fifth degrees. As partially described for the seventh and higher degrees: with examples carried to fifteen and sixteen figures of the root. It is for the facilitation of these solutions that the Abacoa exxpresvis is given, which some have incautiously laid called it 'l'art de la superficie.'

Lagrange's method of transforming the root is based upon a continued fraction ('Theory of Equations,' P. C.) does not need notice here, because it belongs to another mode of expression. But it ought to be noticed that Horner's process very much abridges the labour of Lagrange's method, as much indeed as it does that of Vieta's exxpresvis, and for the same reason. Mr. Exley, of Bristol, in the 'Imperial Encyclopaedia,' article Arithmetic, improved (according to Horner himself) the common method of extracting the cube root, so as toprecede Horner in this particular case. We believe more than one method has been given for finding the successive labour of the ordinary extraction of the cube root: we may mention one which is ingenious and effective, and almost exactly a particular case of Horner's method, given by Mr. A. Ingram, in his edition of Hutton's arithmetic. He gives the sixth, and Mr. Horner himself refers to an edition of Melrose's Arithmetic, by Mr. Ingram (the same, we suppose) as containing such a method.

Mr. Horner's paper was read to the Royal Society on the 1st of July, 1819, and was published in the current volume of the Transactions, on the 1st of December. These dates are of importance: the publication of the above paper was the signal for more than one instance to 'make a new claim to the invention. Mr. Horner was unfortunate in two points. First, he had not sufficient knowledge of antient algebra to be aware that his method contained the process of Vieta, and that his real claim consisted in the discovery of the beautiful process by which the labour is immensely reduced, and completely systematised. Secondly, he appears to desire to be the analyst rather than the arithmetician, and will not show anything except to those who can take all. It is true, beyond a doubt, that his method is adapted to every sort of equation, and that it is as great a help to the person who desires to solve \( \tan x = ax, \) or \( a^m = x, \) as to the other who wants nothing but a common algebraical equation. So far, then, it is more than Vieta's method simplified. But he is the same method as the inventor had proceeded from simple algebra to the more complicated cases, his merits would have been more rapidly appreciated. He did not well see that his mode of solution applies as well to the integral part of the root as to the fractional; nor did he fully comprehend how much of his own discovery consisted in the general mode of calculating the value of \( x \), as given at the beginning of this article. But that we may not do him injustice, and still more that we may enable those of our readers who have not access to the original paper to see how completely he had hold even of the most convenient arithmetical process, we give his solution of the famous Newton's equation, \[ x^3 + 2x^2 + 2x - 7 = 0, \] which is the root by 2, the heads of his columns are 1, 6, 10, and 1 (the first column, which is always vacant, he does not set down). He then annexes either dots or 'ciphers, and proceeds exactly as follows:

As soon as Mr. Horner's paper had been published six months appeared 'A New Method of Solving Equations,' by Theophilus Holdred, London, 1820, (preface dated June 1st) 4to. This was taken from Horner; and a supplement is added, which gives Horner's method. Both are claimed as independent inventions, and Horner's name is not mentioned. Mr. Holdred asserts that, after having had his method for forty years, he was led to that in the supplement* by a mistake; he committed in solving an equation sent him by one of his subscribers. We have given, in the article of the 'Companion to the Almanac,' already cited, our reasons for coming to the conclusion that Mr. Holdred did not see Mr. Horner's paper.
to the conclusion that Mr. Holdred took his first method from Horner, and his second from Horner's.

Mr. Nicholson was the first to publish in various places, which is quite futile. We acquire Mr. Nicholson (a highly respectable man, eminent in the application of mathematics to the arts) of all unfair intention: and we must remind our readers of a point without the knowledge of which the various controv-

ersial writings on this subject will be full of confusion. Hardly any one knew of Viete's Exegesis, which there is little doubt that both Horner and Atkinson reinvented. In fact, so complet-

ed had this expectation dropped out of sight, that even Dr. Peacock, in his short account of Horner's method ('Report on Analysis to the British Association') does not allude to it. Accordingly, all the re-inventors of Viete's method speak of quick and easy for the solution of equations, and treat Horner's process as a constituent part of one of the new inventions. But a person acquainted with the history of the subject finds nothing new except Horner's own. Viete had the main system, Briggs had the Newtonian divisor, Wallis had the method of contraction, Briggs had a method of making one disvisor help the rest: Horner had the method which must finally be adopted.

Budan, as we shall see, had only a particular case of that method, and did not apply it to any mechanical process of numerical solution.

Mr. Nicholson claims Horner's identical process, and fairly refers to the very place in which he says it is to be found. But on looking there (see the article already cited in the 'Companion to the Almanac'), we find that he has been deceived by a distant resemblance, and that, though he has given a new and useful process for a particular purpose, neither the process nor the purpose is Horner's. At the same time it is just to Mr. Nicholson to say, that in his 'Elements of Algebra,' London, 1819,' 3mo, he made as near an approach to Horner's method as could well be done, and applied it in the case of equations of the second and third degrees. The success of columns is seen, each column helps the next, and each step in any one column helps the next step. But the great simplification of which the controversy consists (the non-figure method, is wanting: so that this process of Nicholson's is perhaps hardly more than Briggs was in possession of. Mr. Nicholson had received Mr. Holdred's method, whose name he improperly mentions in the preface. This method had he greatly improved; and it seems he wished that Holdred should publish his amended methods; but he asserts (in the preface to his work on Involution and Evolution) that the latter refused, alleging that his own credit would be dimin-
ished, unless he could pass them as his own.

Dr. Peacock had never seen Holdred's tract, and his result, derived from the assertions of Mr. Nicholson and from Horner's paper, is that Nicholson, by a combination of the methods of Holdred and Horner, reduced the method to its present practicable form. But any one who will solve \[ x^{2} - 2x = 5 \] in the above manner, will see that the process is different from that form. Nicholson was, we believe, the one who first clearly saw that the method, in its simplest organization, ap-

dies as well to the integer as to the fractional portion of a root. All Mr. Nicholson's simplifications, as given in his latest writings, consist in doing in the head some of the things which Horner put down on paper. The form we give carries this still further; and those who can do what we have recom-

mended all arithmeticians to practise in Computation, P.C.S. can follow us: but there is no invention in this.

Some have been disposed to give a good deal of the merit of this system to Budan; and his claim must be considered. Two editions of the 'Nouvelle Methode pour la Resolution des Equations numeriques,' Paris, 4to, were published in 1807 and 1822. The basis of M. Budan's operations is the simple case of Horner's process in which the root of an equa-

tion is diminished by unity. This is done exactly in the mode by which Horner afterwards proceeded. Thus to lessen the root of \[ x^{2} - 2x = 5 \] by unity, Budan proceeds thus:

\[
\begin{align*}
1 & + 0 & - 2 & - 5 \\
& & & & 1 & + 4 & - 1 \\
& & & & 1 & - 4 & + 0 \\
\end{align*}
\]

Answer \((x^{2} - 2x = 5) = 0\) by unity, Budan proceeds thus:

\[
\begin{align*}
1 & + 0 & - 2 & - 5 \\
& & & & 1 & + 4 & - 1 \\
& & & & 1 & - 4 & + 0 \\
\end{align*}
\]

Answer \((x^{2} - 2x = 5) = 0\) by unity, Budan proceeds thus:

\[
\begin{align*}
1 & + 0 & - 2 & - 5 \\
& & & & 1 & + 4 & - 1 \\
& & & & 1 & - 4 & + 0 \\
\end{align*}
\]

\(x = 2 + \frac{1}{2} + \frac{27}{16} + \frac{16929}{20} = 0.4561481364\)

Budan's method is not then even of the same species as Horner's. In an appendix added to the edition of 1822, two years after Horner's paper, there is the method extended to the process for diminishing the root by \(n\) (Horner's process), but no use is made of it, and singly enough the only example given is one in which \(n = 1\). Mr. Horner ('Leyburn's Repository,' page 38, of part ii., vol. v.) denies ever having seen Budan's work until 1818, after his method was finished. This in one point of view, counts for nothing; for every discoverer has a right to have it supposed that those who come after him have used his works: that is to say, he would have a right to the credit thereof arising, even though it could be shown that subse-
quent discoveries were made without his aid. If a partial or unfinished method turn out to have a value of quite a new character when made complete, it is impossible to deny to its author the credit of having been further than his contempo-
raries on the road towards the complete method: conse-

quently, Budan must have, in one sense, the merit of having proposed a particular case of that which Horner afterwards used. But, as it happens, a contemporary of Mr. Horner, in trying to insinuate that he had taken his method from Budan, has furnished independent evidence to the contrary. Mr. Nicholson, in a note to the preface (p. 123) of his essay 'On Involution and Evolution' states: 'I am informed by Mr. Dickson that about twelve months ago he (Horner) purchased at his shop, in St. Martin's-le-Grand, an Essay on the Numerical Solution of Equations, by Budan; on which time he mentioned to me that the author was engaged in something of the same kind.' This called forth the preceding statement from Mr. Horner, who, had he had any unfair intention, and had he really been indebted to Budan, would have argued from the date of Mr. Nicholson's preface that he must have bought Budan only just time enough to insert the note about him in his paper before he sent it to the Royal Society. Instead of this answer, the most straightforward manner, that he bought Budan about July, 1818, nearly two years before Mr. Nicholson wrote; but avers that his method was then finished. And this we entirely believe; and also that it would have been impossible for him, fully engaged as he was in teaching a school, to have produced his method, so as to send it to the Royal Society in the spring of 1819, if he had only seen the first hint in the summer of 1818. But had he seen Budan's work, and had he then conceived the hint which he improved, his merit would not have been the less: Lagrange, the greatest writer on equations then existing, had seen it, Legendre had seen it; and both had closely examined it, and reported to the Institute upon the members of the Institute had seen it. Lagrange, too, knew of Viete's Exegesis. But no one,
except the Bath schoolmaster, ever brought forward Budan's method of consideration of it, either independently, to the improvement of Vieta. Fourier had seen Budan's book, and had invented a method of his own of solving equations; or rather had given his own mode of conducting the method of approximation; but this method is far below that of Horner.

We have written so much on the discovery of this method, because unfair attempts were made by claimants who had no title to it. In the first place we must give the author, whose name we have preserved, the credit of his genius, his rights over his own discovery. We refer to M. Holdred and Nicholson: though we do not believe the second was knowingly unfair. Mr. Atkinson, when he first saw the 'Mathematician's Magazine' (as some called this paper,) saw and said that it was a 'capital improvement.' We have written also because it can hardly yet be said that mathematicians are alive to the value of this grand completion of the systematic and regular method of approximation. It is a process which, at its outset, is not difficult; the Oxford and Cambridge elementary works do not yet recognise its existence. The fact is, that mathematicians dislike calculation, and are apt to form hasty opinions on numerical methods before they have given them sufficient trial. The first elementary writer who brought Horner's method into instruction was Mr. (now Professor) Young, in his Elements of Algebra, published in 1806.

In 1811, eleven years after this method was published, appeared Fourier's posthumous work on equations, containing an extended use of Newton's method. It amounts to employing $q_6$, $q_7$, $q_8$, $q_9$, etc., to calculate the value of $\phi(a-b)$, and of $\phi(a)$, respectively, to calculate $\phi(a+b)$; and so on. Fourier was an expert arithmetician, and in this very work he shows his power of suggesting new forms of arithmetical process; but he does not come near and does not like such an extension of the previous calculation of $\phi(a+b)$, which gives assistance to that of $\phi(a-b)$. The equation $x^3-2x=5$, which Wallis happened to take as his instance of Newton's method, has always been the example on which numerical solvers have shown their power. No one can be said to have carried a method beyond those which preceded, unless he has solved this equation to more places than they have done. Fourier went to thirty-two decimal places, which we do not know that any one had done before. Some students of University College, London, (and one of the College) done exceeding knowledge of years of age, carried Horner's process further still, their independent calculations giving, as the root to 52 figures:—

$$2.09465, 14815, 42226, 59148, 23965, 40579, 30296, 38575, 60105, 62863, 3$$

Mr. Nicholson gives, as the work of a young computer, the following solution of

$$4x^3+7x^2+6x^2+5x+3x+792$$

$$x = 2.05204, 21769, 76905, 36521, 40484, 12961, 20197, 34602, 75999, 54544, 17224, 14$$

We have left entirely out of sight all the irrelevant controversy relating to the method of finding the limits of the roots of such a process as these, when the roots are nearly equal or the same. The claim of Budan, Fourier, Horner, &c., are here mixed up in a manner which requires a sifting investigation. Very frequently the value of Horner's method is stated as depending upon points of this kind. When any of the doubtful cases arise, which we noticed at the beginning of this article, we find, for ourselves, that the ease with which repeated trials are made by Horner's process gives us more command of these questions than anything else; in the case of Fourier's theocrom (Sturm's Theorem, P. C.) is very easily brought to bear by means of it. But it must be admitted, that all methods which in any way include the Newtonian approximation, or any part of it, are much in my opinion equal, in having a better addition to the root already obtained than $-\phi(a)/\phi'(a)$. Let a better method come, and we have no doubt that Horner's process is more ready to make easy use of it than any other. A student who is very slow at finding out the true figures of common division, might with reasonable depreciate the rule of division altogether, as quarrel with Horner's method because there is now and then a difficulty in ascertaining when his work is correct. He might be more easily satisfied with the scholar applying the same process. The same difficulty must exist in every method, as matters now stand. In the meanwhile, we think the discoverer of the process, which is now beginning to take its proper place, should be received with the warmest and most respectful greeting. The name of Horner will be one of the household words of pure arithmetic, and himself looked upon as one of the greatest of its modern benefactors. Justice requires that his name should remain attached to his process.

INWOOD, the family name of three architects, father and two sons, who constructed many public and private buildings in London and elsewhere.

William INWOOD was born about the year 1771. His father, Daniel INWOOD, was half-fellow to Lord Mansfield, at Caen Wood, Highgate, near London. William INWOOD was brought up to the professions of architect and surveyor. He was employed as steward to Lord Colchester, was surveyor to a large number of persons, and several architects now living were instructed by him. He had two sons, one or other of whom was employed conjointly with himself in most of his larger works of architecture, and he was assisted generally in all his professional pursuits by both. He died March 16, 1843, aged about seventy-two. He was the author of 'Tables for the Purchasing of Estates, Freehold, Copyhold, or Leasehold,' a work held in repute by the Remuneration of Churches, Colleges, or other Corporate Bodies, for Terms of Years certain and for Lives, &c., London, 1811, 8vo.; it was written by Budan and Smart. It principally differs from previous works in its method of finding squares and quarters, as well as to decimals of a year; the former being intended for those who cannot read decimal fractions.

Henry INWOOD, the eldest son of William INWOOD, was born May 22, 1794. He was brought up by his father to his own professions. He was several years in Greece, and examined with great care the architectural remains of Athens and elsewhere, and made plans and drawings of them. He assisted his father in most of his architectural pursuits, especially in designing and constructing St. Pancras Church, and had he not suffered so much as he did for many years from ill health, would have been really a great eminence as an architect. His death is supposed to have occurred March 20, 1843, about which time a ship in which he had sailed for Spain was wrecked, and all on board perished.

Henry INWOOD published in 1827 'The Erechtheum at Athens, Fragments of Athenian Architecture, &c., illustrated with Thirty-nine Plates.' The work, which consists of 162 pages exclusive of the plates (engraved by Nicholson), is printed on elephant paper of very large size, and was published by subscription. He had also commenced a work entitled 'Of the Resources of Design in the Architecture of Greece and Other Countries, obtained by the Study of the Architects of those Countries from Nature,' 4to. London, 1834, with explanatory engravings. Two parts were published, but owing to ill health and his untimely death the work was never completed and the life of the author remains of antiquity, most of which are now in the British Museum.

CHARLES FREDERICK INWOOD, second son of William INWOOD, born November 28, 1798, besides assisting his father in his works, was the architect of the church of All Saints at Great Marlow, in Buckinghamshire, which was completed in 1825. He also built the St. Pancras Roman Catholic Church, in Southampton Square, a large plain brick building of little architectural pretension. He died in May, 1840, aged forty-two.

St. Pancras Church, New Road, London, which was the joint work of William INWOOD and his son Henry, is, in its kind and in its peculiar beauties unique among the churches of the metropolis. The building was commenced July 1, 1819, was completed May 7, 1822, and cost 70,767l. The exterior of the body of the church is, with certain necessary deviations, an imitation of the Ionic temple called the Erechtheum on the Acropolis at Athens (ERECHTEIUM, P. C.); the tower is a faithful imitation from the building, and the Tower of the Winds, also at Athens, which is properly the Horologistium, or water-clock, of Andronicus Cyrrhestes. The measurements and drawings of those buildings were made by Henry Howard, the author, and he fixed the spot. The east end of the church supplies the place of the straight west wall of the Pantheon, or temple of Pandrosus, which adjoined the Erechtheum at the west end. The two covered...
buildings which project from each side of the east end, form ing a porch, the caryatids are adaptations from the south portico of the Pandrosion. The caryatid figures, of which there were six, four in front and one at each side, were in the place of columns, and supported the porch. The portico on the upper west north portico had columns. There is one of the original caryatid figures in the Elgin Room of the British Museum. The sarcophagus beneath each roof indicates the purpose for which the projecting buildings were constructed. The two Ionic half columns engaged in the walls on both sides of the west end are additions made to form an apparent basis for the tower. The windows are adaptations modelled in accordance with the form of those of the Sophilos temple; and the material is gray Sulphur brick, with stone facings. It is quite plain except the front and the truncated angles which connect the front with the two ends. The front extends and the door to the entrance, to the entrance of the tower, which projects slightly and is a story higher than the two wings. The entrance is by a flight of stairs beneath a large stone porch constructed in three divisions with flat pointed arches, with the five windows, and the corbelled ornamental stone facings. Above the porch is an oriel window which extends to the height of the two upper stories; and at each of the truncated angles is an oriel window similar to the one over the porch. The tower is built in brick and brick, and divided into four equal compartments by a mullion and transom, but the two upper compartments are distinguished from the two lower by trefoil tracery at the top, and each window is surmounted by a weather-moulding. There are in 260 windows. The brick harmonizes well with the stone portico and dressings, and the general appearance of the front is very handsome. Perhaps the battlemented parapet may be objected to as inappropriate to the purposes of the building, and as less handsome than a parapet of open-work would have been, similar, for instance, to that of Westminster Abbey in the same tower. The deep stone battlements are supported by a wall of stone occupied by the old battlement. The interior arrangements and ventilation are excellent. There are 19 wards and about 250 beds.

William Inwood had the Regent Square Chapel, opened in 1826; the Camden Town Chapel, opened in 1824; and the London Chapel, in Seymour Street, opened in 1826, all of which are chapels of ease to St. Pancras Church. He also built numerous other structures, mansions, villas, barns, warehouses, &c.

(Written Communication; Companion to the Almanac; Knight's London; &c. In Library of Entertaining Knowledge.)

IOWA, a territory of the United States of North America, is bounded on the west by the Missouri river and the White Rock river; on the east, by the Mississippi and a line drawn direct from the centre of the Mississippi to the Lake of the Woods; on the north, by the parallel of 49° N. lat., which separates it from the British possessions; on the south, by the parallel of 40° 30' N. lat., which separates it from the United States. The capital is at a distance of 250,000 square miles, which is nearly four times the area of England, with the exception of Wales. Of the northern part of the territory a very large portion is covered with a vast area of forest, and high ground, called the Coterie des Prairies, which commences about 48° 30' N. lat., and terminates about 43° N. lat., extending in width more than fifty miles between 99° 30' and 100° 30' W. lat.; and the length of the huge mass, which is said to be to 10,000 feet above the surrounding country, has generally a rounded surface, with few irregularities, and is for the most part destitute of trees. East of the Cotcau des Prairies is an extensive valley, in which the Red River runs northward to Lake Winnipeg, and the St. Peter's River southward to the Mississippi. West of Coterie des Prairies is a broad valley of prairie land traversed by the James River, and this valley is separated from the Missouri by a high range of ground similar to the Coterie des Prairies. The number of small streams in this part of the country is extreme, but the upper valley of the river-valleys have been estimated to be more than 1000 feet above the level of the sea. The rest of the country between the Mississippi and the Missouri contains no mountains nor even hills of large size, but consists of rounded slopes with broad valleys in which rivers flow, the upland tracts being connected with the valleys by gentle slopes. Belts of forest occur near the rivers, especially contiguous to the Missouri and the Mississippi, but the flat lands of prairies is covered with bushwood. The south-east part of the territory, which is the only part in which the settlers are numerous, and where the lands have been sold by the federal government, is generally undulating, interspersed with timberlands and prairies, and abounding in springs and streams. This tract, which is very fertile, extends from the Des Moines River south to the Turtles River north, and westward from the Missouri fifty or sixty miles to the Indian boundary.

In Iowa there are numerous rivers, which rising in the elevated grounds of the northern parts of the territory, flow respectively eastward into the Mississippi, westward and southward into the Missouri, and northward into the British possessions. Those which flow into the Missouri are compared in length, breadth, and the number of the southwards of upwards of 400 miles, and falls into the Missouri where that river flows to the coast some distance below Grand Detour. Of the rivers which fall into the Mississippi, one of the largest is the Des Moines River, which is the an affluent of the Cedar River, the Wabashapinae River, the Great Macquenota River, the Turkey River, and the Upper Iowa, are also rivers of large size. Of the rivers which flow northward the Red River is the largest; it rises in the same valley as the St. Peter's River, in Lake Travers, which is near the Big-Stone Lake, and has a course of from 300 to 400 miles northward before it enters the Lieutenant positions, through which it flows to Lake Winnipeg. In the most northern and north-eastern part of the territory, though the elevation above the sea is not much less than 1000 feet, it is a vast and a swampy, and the small lakes. There is a lead-nine district in the south-eastern part of the territory, and considerable quantities of the metal are obtained.

There are no towns yet of sufficient size to require description; the largest are Burlington, Bloomington, Iowa city, Dubuque, and Fort Madison. There is a newspaper published at Burlington. Iowa, the capital, is in 41° 26' N. lat. and 9° 42' W. longitude, from Washington.

Iowa was constituted a territory by an Act of Congress, dated June 13, 1838, and the government commenced July 4, 1838. It was then divided into sixteen counties, and the population, according to the census, was 22,869; in 1840 the population was 43,112; in 1844 it had become 81,920, a rapidity of increase probably exceeding that of any other state or territory in the Union.

The legislative power is vested in a governor, a council of 13 members elected for two years, and a house of representatives consisting of 26 members elected annually. The governor's salary is $2,500 dollars a year, and the secretary who receives $1,500 dollars a year. The members have three dollars a day, and three dollars for every twenty miles of travelling. There are three judges, who are appointed for four years, and who receive $1,800 dollars a year; the territory is divided into three judicial districts, in which the judges perform circuit duties; the supreme court, composed of all the judges, meets annually in July at Iowa city. Congress voted $50,000 dollars for the erection of a building, at the seat of government, for which Burlington was first chosen, but it has been since fixed at Iowa city, where the legislative assembly meets annually on the 1st of December. Congress voted also $5000 dollars towards the purchase of a
The territory sends one member to the House of Representatives.

On the 5th of April, 1844, the people of Iowa passed a vote, by a majority of 2,400, for forming the Territory into a State, which they were entitled to do when the population reached a certain point. The act was adopted, and the Territory, afterwards submitted it to Congress, and claimed to be admitted into the Union as a State. A law was passed by Congress for that purpose, March 8, 1845, which fixed the boundary of the Territory thus:—From the mouth of the Des Moines River to a parallel of latitude passing through the mouth of the Munkato, or Blue-Earth River; thence west along this parallel of latitude to where it is intersected by a line from the mouth of the Mississippi River, W. from Washington, D. C.; thence due south to the northern boundary-line of the State of Missouri; thence east along that boundary to where it intersects the Des Moines River. The Blue-Earth River falls into the St. Peter's River near the point where the St. Peter's changes its course from south-east to north-east. The boundaries fixed by Congress not only very greatly reduced the size of the Territory, as was expected, but differed so materially from the boundaries proposed by the convention, that the people of Iowa refused to be formed into a State on the conditions laid down in the Act of Congress, and Iowa therefore remains still a Territory.

The quantity of public lands sold in Iowa from 1838 to 1844 (but including only the two first quarters of the latter year) was 1,402,624 acres, which produced to the public treasury of the United States 1,293,426 dollars, which is rather a dollar and a quarter per acre. There are still a great number of squatters.

The inhabitants of the Territory of Florida had applied for admission to the Union as a State; in January, 1835, but the application was not granted till March 3, 1845, when it was constituted a state by the same Act which would have admitted Iowa. Florida made no objection to the terms of admission, and is therefore now one of the United States of North America. The extension of the new country and other particulars is given under United States of North America, P. C. S.

IRIS, a genus of plants the type of the natural order Iridacae. It has a tuberous partheni with a petaloid membranous limb, the segments of the sepals revolute, often bearded, three of the petals erect and converging; three stamens, concealed beneath the lobes of the style; the style 3- parted near the upper end with petaloid segments overarching the anthers and bearing a two-lipped transverse stigma below their ends; the capsule 3-seeded, bursting through the cells into three valved coriaceous, with numerous flat or round and drisy seeds.

I. versicolor, Blue Flag, has sword-shaped striated leaves sheathing at the base, a stem two or three feet high, round on one side and flat on the other, and bearing from two to six flowers. This plant is a native of swamps and wet meadows in the United States. The rootstock has a nauseous acid taste. It acts as a cathartic, and its action is attended with great depression of the nervous system and prostration of strength. It also acts upon the kidneys, and is useful in cases where diuretics are indicated.

I. pendul-accus, Yellow Flag, has sword-shaped leaves; the stem round; perianth bell-shaped, its inner segments narrower and shorter than the stigmas. It is a native of wet places in Great Britain, France, Germany, and most countries of Europe. The rootstock is acrid and possesses an emetic and cathartic action. The seeds when roasted are sold to form a good substitute for coffee.

I. Florentina, Florentine Iris, has broad and somewhat falcate leaves shorter than the stem, the petals two inches long, bright yellow, red, and rose and red spotted towards the base. The dried rootstock is known in the shops under the name of orris-root. The plant is a native of the southern parts of Europe and the islands of the Mediterranean. The rootstock has a subacid taste, and is employed as a dentifrice. It enters into the composition of Ruppin's tincture and tooth-powder, and other popular dentifrices. It was at one time used in medicinal preparations, and in the middle ages the rootstock acts as a purgative, and was also employed as an expectorant in diseases of the chest. When dried and turned into small balls it is used for issue-pees. According to Subilhac and Thory, it is found in Greece, on the coast of the Troad, and it is called Hiero of the Persians, 2, 673) and the Ipsi (aphae) of Theophrastus (Hist. Plant., 7, 12).

I. petalodiscus, Stinking Flag, has sword-shaped leaves, but in the stem and leaf the plant has a disagreeable odor, and is offensive to animals; it is used as a purgative and aperient as long as the stigmas. This plant is a native of Great Britain and other parts of Europe. It has a peculiar small worm, which some have compared to roast beef, but which is remarkably imperfect in its external and less pleasant associations. It is the Ipsi (aphae) of Theophrastus (Hist. Plant., 9, 8) and Ipsi of Dioscorides (4, 12).

I. tuberosa has tetragonal leaves, the segments of the perianth broad, the flowers without filaments, the capsule elongated, and the seeds eaten in Siberia. I. edulis is eaten by the Hottentots of Africa, where it is called Ooja. All these species are cultivated in gardens on account of handsome showy flowers.

(Franc. Synopsis Florae Classicae; Lindley, Flora Medica; Subilhac, Flora Graeca; Buchanan, Manual of British Botany; Burnett, Outlines of Botany.)

IRISH MOSS. [Cladaria Islandica, P. C. S.; Sea Wrack, C. P. C.]

IRON RATS AND SHIPS. [Ship-Building, P. C., p. 395.]

IRRADIATION denotes, properly, the emission of rays from a luminous object, but the word is generally used to signify an apparent enlargement of the disc of a celestial body when this enlargement is being caused either by a deviation of the rays of light from a rectilinear direction, or by some illusion arising from the action of light on the eye.

When rays of light fall upon the surface of an object fall on the retina, there may be produced on the latter an agitation extending within short distances about the points to which the rays in the pensile are made to converge by the humours of the eye; hence there may arise a perception of a fringe or border about a luminous body, and consequently an apparent enlargement of such body. Thus the image of a star, when seen by the eye, appears to be a disc of sensible magnitude, instead of a mere point; which, on account of its remoteness, would be the case if the rays of each pencil produced no effect beyond their mathematical point of convergence; the disc of the sun or of the moon is conceived to be, in like manner, apparently enlarged; and thus, also, the part of the moon which, when the latter is nearly new, is enlightened by the sun, appears to be a portion of a sphere of greater diameter than the earth, on which is a mass of land which is more faintly enlightened by the rays reflected from the earth.

A species of irradiation is caused by the blending together, upon the retina, of the circles of light produced by the pencils from the different points; and if after rays in this manner convergent to a point; the humours of the eye not permitting that convergence to take place exactly on the membrane.

[ENLARGEMENT OF OBJECTS. P. C. S.]

Before the invention of telescopes, the apparent magnitudes of celestial bodies were very erroneously estimated; thus, Tycho Brahe made the diameter of Venus twelve times, and Kepler made it seven times as great as it is now known to be. Telescopes do not entirely remove the cause of such error, but, by diminishing the apparent brightness of the bodies, the error in the estimation of their apparent magnitudes is proportionally diminished. Du Séjour, Lexella, and other astronomers, on calculating the diameters of these bodies by the length of the contacts of the sun and moon in eclipses of the former have, in order to produce an agreement between them, found it necessary to diminish the apparent semidiameters of the luminaries in each; and on account it is supposed, of the effects of irradiation.

It is a consequence of irradiation, that objects which are in reality of equal magnitudes appear frequently to differ in size five or six times; in the day of the full moon there is no irradiation; and hence the large errors of Tycho and Kepler now no longer correct the calculations of their contemporaries. Sir William Herschel remarked (Phil. Trans., 1783) that when a bright circle was viewed together with a dark one on a bright ground, the latter always appeared smaller than the former. The new calculation of the erroneous estimate of the magnitudes of the objects about the earth is, when seen against a bright ground, it appears
that the antients made the thickness of the columns to increase proportionally to the distance between them. The reason assigned for this practice by Vitruvius (De Architectura, lib. 3, cap. 2) is that the columns with wide intervals, being more susceptible to the effects of heat and ponds in the summer, appear to be placed on account that is to be more slender: it must be observed, however, that the perceptions of magnitude depend partly on those of distance; and a contrary effect frequently takes place with objects viewed in the distance, as when concealed to be more remote than they really are.

ISATIS. [Walp, F. C.]

ISCYPOUS, a genus of fossil fishes included in Chimeridae.

ISNARDIA, a genus of plants named by Linnaeus in memory of M. Antoine Dante Isnard, member of the Academy of Sciences. It belongs to the natural order Orogynaceae, and has 4-cleft calyx, 4 petals, 8 stamens, and a filiform style, with a clavate or cruciform stigma. There is one British species of this genus. *I. palustris* has a procumbent rooting glabrous stem, opposite ovate acute leaves, terminating in a petiole axillary sessile flowers, with the petals absent. It is found in pools and marshes in Europe, Siberia, and Persia, and in Sussex in England.

*I. alterefolia* has an erect branched stem, alternate leaves, rather hoary and hoary beneath. It is a native of Virginia and Carolina, in marshy places, and has oval yellow petals. The root is used as an emetic, and is called 'peco.

None of the species of this genus possess qualities which entitle them to cultivation except in botanical gardens. They may, however, be reared in a hot-bed, and then planted in an open garden in a sunny place.

(Dow, Gardener's Dictionary; Bebbington, British Botany.)

ISOCROMATIC LINES are those coloured rings which appear when a pencil of polarized light is transmitted along the axis of a crystal, as mica or nitre, and is received in the eye after passing through a plate of tourmaline. If a plate of nitre having its surfaces perpendicular to the axis of the natural crystal is held in a horizontal line, and beneath it is placed one plate of tourmaline having its axes at right angles to another, and a lens of short focus be placed so as to transmit the light of the sky through the plates to the eye of the observer, that focus falling a little below the surface of the nitre, the rays of light will be polarized by passing through the first plate of tourmaline, and there will be seen a series of oval rings, about each of two points as poles, forming together figures which may be considered as resembling lemniscates.

By the nature of the lemniscate, the rectangle contained by the two lines drawn from the poles to any point in the curve is constant; and the curves have received their designation from the Greek word *lemniscus* (a rope or cord), as the equivalent of such rectangle for that curve: when the light is viewed through plates of nitre of different thicknesses, the tint depends also on the thickness of the plate.

The rectangle is also the average area of a sphere of which a point in the crystal is the centre; and when the optical axes of the crystal are at a considerable distance from one another, when the curves be projected on a plane, the tint in each curve will depend on the product of the sine of the angles subtended by two lines drawn from the poles to a point in its periphery, and also upon the length of the path described by a ray of light in passing through the crystal.

ISOCRINITES, a genus of Crinoids (Goldfuss).

ISOLETUS, a genus of fossil Crustacea (Trilobites) from the Silurian strata, especially of North America (Greev).

ISSUE PEAS are round bodies employed for the purpose of maintaining irritation in a wound of the skin which is called an issue. [Lucas, F. C.] It is a matter of indifference of what substance these are composed so long as they do not introduce poisonous matters into the wound. The seed of the common garden pea is frequently used. It is however more common to use the young unripe fruits of the common orange (Citrus aurantium). The fruits are dried and afterwards turned in a laths before they are used as issue peas.

The unripe oranges, dried, are sold under the name of orangettes or Carsons oranges. The rootstock of the Iris florentina is also formed into peau and used for keeping up the discharge from issues.

(Johannes, Flora Medica; Christison, Dispensatory.)

IULUS, a genus established by Linnaeus for such Insecta as belong to the Order Myriapoda as well as the Order Chilognatha, the first division of the Order Myriapoda in the arrangements of Leach and Latreille. The Chilognatha have crustaceous and usually cylindrical bodies, formed of numerous unequal segments. They have very short feet, with two joints, the anterior being curved. They have a rounded head, furnished with two mandibles, which are either thick and robust or united with the labium and elongated. They have no palp. The antenna is two, very short, either slightly thickened towards their extremities, or filiform throughout, and composed usually of seven, more rarely (as in the genus Spharopus) of six joints. Their eyes are smooth and vary greatly in number. They are predatory animals moving slowly and with a gliding motion. When disturbed, they roll themselves up spirally, or into a ball. They feed on decomposing animal and vegetable matter.

The position of the first part of the name is, of the Chilognatha, at the head of the Myriapoda, by Latreille and others, has been recently disputed by Professor Brandt and by Mr. Newport. The following remarks on this subject by the latter naturalist, of all living zoologists the most competent to decide in questions affecting this difficult class, are taken from his catalogue of Chilognatha in the British Museum, published in the *Annals of Natural History* for April, 1844, and afford in a brief compass much important and accurate information concerning these curious animals.

The Chilognatha have usually been regarded by naturalists as the first order of the Myriapoda, partly in consequence of the more compact form of the head, and its similarity to that of the Ants and Spiders, and also of the general form of their bodies being similar to that of the larve. This was the view taken of these animals by Latreille, Leach, Gervais, and some others, and very recently by Lucas. But a different and, as I believe, more correct view and arrangement...
ment have been followed by Professor Brindly, who regards the *Chilopoda* as the first, and the *Chilagnosta* as the second division of the class. Although I cannot entirely agree with Brindley in his division of the *Chilagnosta* into mastacating and sucking species, because, as Lucas has recently remarked, there are species even among the *Chilopoda* which have the external organs of nutrition fitted only for taking liquid food, as *Spirastreptus*; I cannot deny that, in the *Chilagnosta*, a pointment on one hand, and to the Arachnida on the other. The form of the head, in the two divisions of Myriopoda, seems to have reference chiefly to the particular habits of the species respectively. Thus, in the *Chilognatha* the greater part of the head is devoted to the mastacating and sucking habits; in the *Chilagnosta* the greater part of the head is devoted to the foot-jaws. In the *Chilopoda* the foot-jaws have the form of true mandibles, because the habits of the species require that compact form of jaw, which alone can be subservient, not to the seizing and piercing of living prey, but to the grinding or comminuting of more or less solid vegetable matter, on which most of the genera of Chilagnosta entirely subsist. In all other respects, both in their internal as well as in their external anatomy, and in their physiological and mode of growth, the *Chilagnosta* are decidedly inferior to the *Chilopoda*. They may be made to conduct us down to the Amelaidae from the vegetable-feeding features, as the *Chilopoda* do from the Arachnida to the same class.

The Chilagnostae: or Myriopoda are found in all parts of the world, certain genera, however, affecting certain geographical divisions. Thus the species of *Eremurus* are European; those of *Spirastreptus* and *Sphaeroenas* African and Eastern. The genus *Iulua*, in its most limited sense, includes European, Asiatic, and North American species. *Iulua terrstriss* is a familiar British example.

A synopsis of the genera of Chilagnosta will be found in the third part of the nineteenth volume of the "Linnean Transactions," appended to a valuable memoir on the Myriopa by Mr. Leidy. In a subsequent paper on these animals, published in the "Transactions and Proceedings of the Imperial Academy of St. Petersburg," Mr. Leidy says, a distinguished mathematician, born at Dundee, in 1765, and received the rudiments of education in the public schools of that town. At fourteen years of age he was sent to the university of St. Andrew's; his father was a watchmaker, in that town, to which he became a clergyman of the church of Scotland. In that university the young man remained six years, during which time he was occupied with the study of mathematics, languages, and philosophy; but the first of those subjects, from a natural inclination to that branch of science, particularly engaged his attention: he was encouraged and helped in his favourite pursuit by the Rev. John West, one of the instructors at the university; and his great progress, which is said to have excited considerable notice, gave early indications of the eminence which, as a mathematician, he was afterwards to attain. The two following years were passed in further pursuit of his studies; and Mr. Ivory, in company with Mr. (afterwards Sir John) Leslie, who had been his fellow-student at St. Andrew's, to the university of Edinburgh, where he spent one year in completing the course of studies required for admission to the office of minister in the Scottish church.

It is not known what circumstances prevented Mr. Ivory from carrying out the intentions of his father in this respect; but it appears that about that time he was appointed as an assistant teacher in an academy then recently established in Dundee, and he continued to fulfil the duties of that post during three years. At the end of that time he engaged upon a project of establishing a school in Doughterton in Forfarshire, of a factory for spinning flax; and of this association he appears to have been the principal person.

During fifteen years (from 1789 to 1804) Mr. Ivory was employed daily in operations apparently very unconnected with the taste of a man of science; but it may be presumed that all his leisure hours were devoted to the prosecution of scientific researches. There have been at this time, that, though residing in a retired district, he, with the aid of the English mathematicians, together with those of the illustrious foreigners whose works were in the public libraries of Scotland and in the same kind at other places. He was thoroughly acquainted with, the later productions of the mathematical sciences. It is scarcely to be expected that a factory carried on under the supervision of a man of greater part of whose time was probably spent in researches which require nearly a total abstraction of the mind from the ordinary concerns of life, should have succeeded; accordingly we find that in 1804 the company ceased to exist; and Mr. Ivory, who then obtained the appointment to a professorship of mathematics in the Royal Military College, quitted Scotland, and went to reside at Marlow, in Buckinghamshire, where that institution had, a few years previously, been founded. On the removal of the college to its present site (Sandhurst in Berkshire), Mr. Ivory accompanied it to the latter place, where he remained till his retirement from public service. He fulfilled the duties of his appointments so well as to obtain the respect of his superiors; his attention to the students who were placed under him was unremitting; and it should be remarked that, however irksome it might have been to a man of high attainments in science to compose the base materials of his work, the compilation of a translation of Mr. Ivory always evinced the utmost readiness to assist, by the most appropriate and familiar illustrations, in smoothing the path of science to the pupil. An edition of Eudox's "Elements," which is known to have been his work, though his name does not appear on the title-page, was prepared by him for the use of the students in the college; and the manner in which he has treated the book on proportion, and those which relate to solids, must have great advantage in elucidating the general ideas of learners in experience in acquiring a knowledge of those parts of elementary mathematics. In the beginning of the year 1819 Mr. Ivory, feeling his health declining under the great exertions which he made in carrying on his scientific researches and performing his duties as a professor, those duties leaving him but short intervals of leisure, was induced to resign his professorship and retire into private life. In consequence of his great merit there was granted to him the pension due to the full period which, by the regulations, the civil officers of the institution are required to serve previously to obtaining such pension; and which period he had not served before his retirement from Sandhurst, Mr. Ivory devoted himself wholly to scientific researches, and the results of his labours have been printed chiefly in the columns of the "Philosophical Transactions." In 1831, in consideration of the great merit displayed in his investigations, he was by Lord Brougham, to whom he had been known in early life, recommended to the king (William IV.), who, with the Duchess of Kent, made an Order of Knighthood, gave him an annual pension of 500L., which he enjoyed during the rest of his life; and, in 1839, the University of St. Andrew's conferred on him the degree of doctor in laws. He lived in great privacy in or near London till the time of his death, which happened September 21st, 1844, in the seventy-seventh year of his age.

Mr. Ivory's earliest writings were three Memoirs which he communicated in the years 1796, 1799, and 1802 to the Royal Society of Edinburgh: the first of these was entitled "A New Series for the Rectification of the Ellipse;" the second, "A new Method of resolving Cubic Equations;" and the third, "A new Method of resolving Cubic Equations, all of them radical results, and a mathematical solution of the problem;" all of them evinced great analytical skill, as well as originality of thought. He contributed fifteen papers to the "Transactions of the Royal Society of Edinburgh," nearly all of which related to mathematical and scientific researches, and mathematical investigations of the most refined nature. The first, which is entitled "On the Attractions of Homogeneous Ellipsoids," is in the volume for 1809, and contains investigations of the principal problems of astronomy, and in several instances within and on their exterior: the former case presents few difficulties; but the process used by Laplace for the solution of the other was very complex, and Mr. Ivory had the merit of reducing it to simpler form. A given point being on the surface of an ellipsoid, he hus-
glided another ellipsoid having the same centre and the same loci as the first to pass through the point; then taking, on the surface of the interior ellipsoid, a point so situated that the co-ordinates of the two points are in the ratio of the semiaxes to which they are parallel, he showed that the attraction in the direction of each axis is that of the two ellipsoids exercises upon a point on the surface of the other, is to the attraction of the latter body on the corresponding point at the surface of the first, as the product of the two other axes of the first ellipsoid is to the product of the two other axes of the second.

A direct investigation of this case has since been given by M. Poisson.

In the volumes for 1812 and 1822 there are three papers on the Attractions of Spheroids, in which Mr. Ivory substituted a refined analytical process for the indirect method of Laplace: the papers contain also some observations on the method employed by that great geometer in computing the attractions of spheroids of any form differing but little from spheres. The analytical skill shown by Mr. Ivory in these papers was frankly acknowledged by Laplace himself in a conversation which, in 1826, he had with Sir Humphry Davy.

The Transactions for 1814 contain an investigation, by Ivory, relating to the orbits of comets, on the supposition that these orbits are parabolical: the paper is entitled 'A New Method of deducing the first Approximation to the Orbit of a Comet from three Geocentric Observations.' And the volumes for 1823 and 1828 contain his investigations relating to Astronomical Refractions: in the first of these the temperature of the air is supposed to decrease uniformly with a uniform increase of height; and in the other the expressions are rendered general for all laws of temperature. The volumes for 1824, 1821, 1824, and 1839 contain, each, a paper on the equilibrium of fluid bodies; and in the volume for 1828 Mr. Ivory demonstrated that a homogeneous ellipsoid with three unequal axes may be in equilibrium when revolving about one of the axes: he also examined in detail the limitations of the proportions of the axes. The subject of planetary perturbations is treated by him in two papers which are contained in the volumes for 1832 and 1833; in the first he has simplified the theory of the variations of the elements, and in the other he has given some facilities for developing the eccentricities and inclinations. He has given in the 'Transactions' only one paper which is purely mathematical, and this is contained in the volume for 1831; it is entitled, 'On the Theory of Elliptic Transcendents.'

Mr. Ivory contributed several papers to the 'Philosophical Magazine': in the number of that work for August, 1821, he describes the method of finding the latitude of a ship by two observations of the sun's altitude, with the time elapsed between them; and in the volumes for 1825 and 1827 are his investigations relating to sound and heat. Several valuable communications from his pen are contained in Maureva's 'Scriptores Logarithmici'; in Leybourn's 'Mathematical Repository'; and in the Supplement to the sixth edition of the 'Encyclopedia Britannica.'

In estimating the merits of Mr. Ivory as a mathematician, it must be borne in mind that his researches were conducted by a most refined analysis at the time when even the notation of the differential calculus was not familiar to the English mathematicians; and that, when he wrote the papers relating to the attraction of spheroids, the volume of the 'Mémoires du Céléste,' in which that subject is treated, had probably not been read by anyone in this country except himself.

In 1815 Mr. Ivory was elected a fellow of the Royal Society of London: he was also an honorary fellow of the Royal Society of Edinburgh; an honorary member of the Royal Irish Academy, and of the Cambridge Philosophical Society; a corresponding member of the Institute of France, of the Royal Academy of Sciences of Berlin, and of the Royal Society of Göttingen. He received, in 1814, the Copley medal for his mathematical communications to the Royal Society; in 1826 one of the royal medals was awarded to him for his paper on Astronomical Refractions, published in 1823; and in 1839 he received another royal medal for his Theory of Astronomical Refractions, which was published in 1838.

(From the Marquis of Northampton's Address to the Royal Society, November 17, 1842.)

IVY. [Hedera, P. C.]

IZALCO is the name of a village in the State of San Salvador in Central America, and remarkable for a volcano situated about three miles from the village, and between eight and nine from the town of Zemeneate. This volcano is of recent origin. It is stated that it was formed about sixty years ago, and it is to be regretted that no particular account has hitherto been published of such a remarkable event. It broke out on the top of a hill of moderate elevation, which however since that event has been increased in size by the addition of lava, scoria, ashes, and other volcanic matter, and at present it may be called a considerable mountain. It is one of the few volcanos which are in uninterrupted activity, like the Stromboli of the Lipari Islands. The eruptions are almost continual, and whenever they slacken the country in its vicinity is subject to almost continual earthquakes. Sometimes the activity of the volcano is increased, and then large quantities of lava inundate the country at its base, the greater part of which has thus been changed into a stony waste.

(Burnett, Outlines of Botany)

JACKSON, JOHN, R.A., was born in 1778 at Lustingham, in Yorkshire, where his father carried on the business of a flour and meal dealer. He was brought up to the same business. He however hated his occupation; he had seen the collection of Lord Mulgrave, and the pictures at Castle Howard, and he had a strong inclination to become a painter. An attempt which he made without a patron by painting a portrait by Reynolds was shown by his schoolmaster to Lord Mulgrave, who receiving it in and others, notwithstanding their eminences, some talent, supplied Jackson with proper materials, and encouraged him to go on. Lord Mulgrave and Sir G. Beaumont purchased the two years of Jackson’s unexpired apprenticeship, and the latter in 1797 gave him an allowance of 50l. per annum, and an apartment in his house in town, to enable him to prosecute his studies at the Royal Academy.

Jackson soon obtained a name for his portraits in black lead-pencil and water-colours, but it took him many years to equal the successful oil-painters of that day. He first attracted notice in this department about 1806, and in 1817 when he was elected a member of the Royal Academy, his reputation was little inferior to that of Lawrence, though he was comparati

sombre but well-planned portraits, and in his portraits of the moderns and of the English nobility, they had the delicacy of the works of Lawrence: Jackson could paint five heads while Lawrence was painting one.

In the summer of 1819 he visited Rome in company with Chantrey, and painted for him there a portrait of Canova. Jackson astonished the Roman painters, says Cunningham, by copying in four days the Borghese Titian of ‘Sacred and Profane Love’ as it is called, a picture which many Romans required the other three months to copy; Passavan

...one of the three most remarkable portraits in the world.

Jackson exhibited in all, at the Royal Academy, between the years 1804 and 1830, one hundred and forty-five pictures; but his best works are the portraits of Mr. and Mrs. Lincoln, which he was sometimes paid for, and also for one of his fellow-academicians, but that of Flaxman, is in all respects the best; Allan Cunningham truly observes of this picture, that there is a 'sombre grandeur about it which answers one; it is certainly one of the finest portraits in the world.'

Jackson exhibited, in all, at the Royal Academy, between the years 1804 and 1830, one hundred and forty-five pictures; but his best works are the portraits of Mr. and Mrs. Lincoln, which he was sometimes paid for, and also for one of his fellow-academicians, but that of Flaxman, is in all respects the best; Allan Cunningham truly observes of this picture, that there is a 'sombre grandeur about it which answers one; it is certainly one of the finest portraits in the world.'

In November, 1812, the next year he greatly distinguished himself by a campaign against the Creeks. An account of it may be found in a message from the President (Madison) to Congress, dated 7th December, 1813, in which it is stated that the best hopes of a satisfactory issue of the contest were already warranted by the complete success of a well-planned enterprise against the Indians, executed by a detachment of the volunteer militia of Tennessee under the command of General Coffee; ‘and by still more important victory over the larger body of them, gained under the immediate command of Major General Jackson, an officer equally distinguished for his patriotism and his military talents.’ The Creeks were repeatedly afterwards defeated by Jackson. The war was not terminated by the Treaty of 1814, but the Indians agreed to lay down their arms. (Message of President Madison, dated 20th September, 1814.)

In 1814 Jackson was appointed a Major General in the service of the United States. After the conclusion of the hostilities, he succeeded in taking Pensacola on the 7th of November, and raised himself to the highest point of reputation and popularity among his countrymen by the famous repulse of the British in the battle of New Orleans, January 8th, 1815. The next military command which he held, was that of Andrew, his latest born, appears to have been his mother’s favourite; and the original destination of the future General and President of the United States was to be a clergyman, we are not informed of what denomination. With this view, after having finished his school education, he was sent to the Waxhaw district of South Carolina. After completing his theological studies for some years. When the war of independence, however, made all Americans soldiers, the young Jackson did not hold back. Andrew is recorded to have fought, along with his next eldest brother, Robert, under Sunbury in his attack on the British garrison at Rocky Mount, on the 6th of August, 1780; at which date he would be little more than thirteen. And from this time he is stated to have taken a part in the campaigns as long as the war lasted. Nor did he altogether escape the usual dissipated habits of a military life; but, with the decision of character which was his most remarkable characteristic, he suddenly changed his course before it was too late, and, collecting what remained of his means, put himself, in the winter of 1784, into the hands of Spence McCay, Esq., an eminent advocate and afterwards a judge, to be instructed in the practice of the law. This new study he prosecuted with so much success that in 1787 he was appointed solicitor for what was then called the Western District of North Carolina, and is now the State of Tennessee. The battle of the seven - days campaign in 1781, when he, if he had been so inclined, to throw off his military character, or to let the experience he had gained in camps and campaigns go to rust. Although the war with the mother country was over, the "virile" of the republican territory were still infused with another most troublesome enemy in the original occupants of the soil; and Jackson, although he would only serve as a private, is said to have so much distinguished himself in his first campaign with these natural rivals of his race, that he was honoured among them with the titles, or descriptive appellations, of "Starb Knife and Pointed Arrow." He continued to be thus employed till the year 1796, when, after having first acted as one of the members of the Convention for establishing a constitution for the state of Tennessee, he was, under that new arrangement, elected to a seat in the House of Representatives. The next year he was chosen a Senator; but he resigned his seat after holding it for one session. On this he was immediately appointed by the legislature of Tennessee Judge of the Supreme Court in that state; having also been shortly before chosen a Major-General of the state forces. But he soon resigned his judicial office; and, settling himself on a farm, a few miles from Nashville, on the Cumberland river, he resided there in retirement till the breakin...

JAC

the war against the Seminole Indians of Florida in 1818, for
the details of which the reader may refer to Mr. Monroe's Message to Congress of the 16th of November in
that year, and to the Report of the Committee of Senate on the
Seminole war, dated 24th February, 1819. Jackson's
proceedings in this, for which he obtained a tremendous
triumph, consisted of the force at the head of which he
placed himself was raised and officered not only without but
in direct opposition to the orders of the general government; in
carrying on operations, conduct of his government marked the
disapproval in the most emphatic manner, by the immediate
restoration of the places thus unwarrantably seized; but his
most extraordinary act was the execution of the two English-
men Arbutnot and Ambrister. Alexander Arbutnot was
taken in the Spanish Fort of St. Mark's, along with two
Indian chiefs, and Robert C. Ambrister, a few days after-
wards, on an excursion which the force made from that post
to destroy a neighbouring Indian village. The two Indian
chiefs were hanged at once, and without trial; the justifica-
tion urged being that by their own usual practices in like cases,
and by the general manner in which they carried on war, the
Indian nation had thereby passed over the two hundred and
twelve miles beyond the pale of the ordinary law of nations. Arbutno-
t and Ambrister were both, after a few days' confinement, tried
at St. Mark's by court martial; when Arbutnot was sen-
tenced to death, but, under the direction of the judge, he
further confided; but General Jackson annulled the latter
sentence, and Arbutnot hung and Ambrister shot.
There is no doubt that these persons were acting in concert
with the Indians, and, that being the case, it would perhaps
be difficult to show that they were entitled to other treat-
ment than those with whom they had associated themselves.
But even to take the lives of Indian prisoners of war was an
extraordinary proceeding, and one which would have appeared
unsuitable to the charge upon which the two Englishmen were tried was only
the very vague one of 'insecting the Indians to war'; in
circumstances it was certainly a startling exercise of military
power. The government, under the popular mayors of all
governments, to set aside the sentence of a court martial,
as was done in the case of Ambrister. Besides, the principle
upon which General Jackson took his stand was even less tenable
than the one we have just stated; he himself vindicated what
he had done, on the ground that Arbutnot and Ambrister,
by assisting in war against the United States while they were
at peace with Great Britain, became outlaws and pirates; thus
resting their liability to suffer death, when taken prisoners of war,
ot on the ground of their having united their forces with savages, but on that of their having been the
subjects of a power with which the United States were at
peace, on the ground, in short, that their actions were in utter
dissension of that place against the army of the Convention; his
second son, then a youth of fifteen, fought by his side. Being
bounced from the reduction of Lyon, they were both com-
pelled to fly, and they then joined the army of the Rhine.
His son was killed in it, and he was left without a friend
who would have been unable to support him in all this, for
how could he return to Lyon, where he had found his wife, whom he had been so
able to inform of his flight, earning her bread by plaiting straw,
in which humble occupation he was compelled by poverty to
exist. Lyon and his son attended tologgedIn repudiation of
the United States, and their artisans returned from Switzerland, Germany, and
England, where they had taken refuge. Under these circumstances,
Jacquard applied himself with renewed energy to the per-
fection of the beautiful apparatus for figured weaving which
bears his name, and which is described under Weaving, P. C.,
p. 178. He had conceived the idea of such an appa-
ratus as early as 1790, and it was so successfully, though but
imperfectly, in accomplishing his end. His machine
was presented, in September, 1801, to the national exposition of
the products of industry, the jury of which awarded him a
gold medal. In the following year he obtains a patent, or
brevet d'invention, for a term of ten years. He
set up a loom on his new principle at Lyon, which was visited by
Carnot and several of the statesmen who were as-
sembled at that city in 1802 to arrange the affairs of the
Chalaine republic.
About this time the attention of Jacquard appears
were have been directed, by the accidental perusal of a paragraph from
an English newspaper, stating that a new society in this country for the invention of such an apparatus,
the construction of a machine for weaving nets for fishing
and maritime purposes. From the account given by Dr. Bowring, who had written
his autobiography for himself, before a Select Committee of the House of Commons
on the silk trade, in 1882, and which is made the subject of

P. C. S. No 100

Vol. 11. 2.
article in No. 56 of the 'Penny Magazine,' published in 1833, this would appear to have been Jacquard's first mechanical invention. It is more correctly accounted for in his 'Supplement' to the 'Biographie Universelle,' to which we are chiefly indebted for the materials of this article, shows that such was not the case. He accomplished the desired object by one of those ingenuity which his friends with some contrivance, he threw it aside. His machine-made net, however, fell into the hands of the prefect at Lyon, and the result was that, according to the arbitrary fashion of the time, he and his friends were placed under arrest and conveyed to Paris, where the invention was submitted to inspectors, upon whose report a gold medal was awarded to him in February, 1804. On occasion of this forced visit to Paris, Jacquard was introduced to Louis Bonaparte, who, in the latter, understanding his mechanism, roughly asked him if he were the man who pretended to do that impossibility—to tie a knot in a stretched string. Jacquard, not disconcerted at such a reception, explained the action of his machinery with simplicity, and convinced the incredulous minister that the supposed impossibility was accomplished by it. He was then employed for a time in repairing and putting in order the models and machines in the Conservatoire des Arts et Metiers, and while there he produced some ingenious improvements in weaving machinery, one of which was for producing ribbons with a velvet face on each side. He also contrived some improvements for Vaucanson's loom, and with this new mechanism, improvements have been stated to be the origin of the Jacquard machine. According to the French authority above referred to, however, this improvement upon Vaucanson's loom may have been combined with his greater mechanism; that is to say, a very complex, its application limited to very small patterns, its action slow, and its cost very great, it is considered to belong rather to the class of curious than useful machines.

In 1804 Jacquard returned to Lyon, where he was long engaged in superintending the introduction of his inventions for figured weaving and for making nets, in which he was protected by the firm of the illustrious Jacquard brothers in that city. Through his assistance, a commission of manufacturers was appointed to report upon the first-named invention, and eventually an imperial decree, dated Berlin, October 27, 1806, was issued to authorize the municipal administration of Lyon to purchase his invention for the use of the public. In the same year the Academy of Sciences and Arts at that city presented him with the prize medal founded by the consul Lebrun. For some years Jacquard had to struggle against much opposition and prejudice on the part of the Lyonnais weavers, who conspired to discourage the use of his machinery, willing to spoil their work to bring it into discredit, and, through the Conseil des Prud'hommes, to which he was appointed, to watch over the commercial interests of the city, had it publicly broken up and sold as old materials. Even his personal safety was at times endangered. At length, however, under the influence of foreign appetites, the value of his inventions was acknowledged, and it was brought very extensively into use, not only in France, but in Switzerland, Germany, Italy, America, and, according to the 'Biographie Universelle,' "it has been introduced into China.

Jacquard was solicited by the manufacturers of Rouen and St. Quentin to organize their factories of cotton and batiste, and he received a tempting offer of a similar nature from England; but he preferred remaining at Lyon, where he continued to exert himself in promoting the use of his great invention until, having lost his wife, he retired to Oullins, a village near Lyon, where he spent his latter years in retirement, and died on the 7th of August, 1834, at the age of eighty-two. During his life he received the cross of the Legion of Honour, and in 1849 a public statute was raised to his memory. His 'Elcoge Historique' has been published by M. de Fertis.

The name of Jacquard, observe the writers of his memoir in the 'Biographie Universelle,' 'has become, so to speak, a term in the dictionary of old and new words, and a synonym of the inventors of the Vaucansom, who, like him, was engaged at Lyon in the improvement of weaving machinery. Jacquard has invented a simple and cheap machine, coming with a history of its introduction, as some learned the humble weaving art, which forms a memorable epoch—a new era—in the textile art.' By its agency the richest and most complex designs are produced with facility at the most moderate price; and, so far from an impediment, as some have stated on its first introduction, it has, according to the writers just quoted, increased the number of workmen in the manufacture in which it is used.

JALNA (Jalnapoor), a town of Hindustan, capital of the district of Jalna, is included in the province of Agra. The district of Jalna is comprised chiefly of two large valleys, one of which is watered by the Pouna and the other by the Jalna. Jalnapoor is a fortified town of considerable size. It was taken from the Maharattas by Colonel Stephens in November, 1803, in the course of the military operations which immediately preceded the battle of Assaye, and was afterwards ceded to the Nizam.

JAMESONE, or JAMESONE, called by Walpole the Vandyck of Scotland, was the son of Andrew Jamesone, an architect, and was born at Aberdeen in 1686. Jamesone and Vandyck were about 1618 fellow-pupils of Rubens at Antwerp. When Charles I. visited Edinburgh in 1616, he set to Jamesone, and presented him with a diamond ring from his own finger. He was probably in Italy, for his portrait is in the painter's portrait gallery at Florence; he travelled in company with Sir Colin Campbell of Glenorchy. Many of the conditions of his life are given by R. Reilly, 'Memoirs of Sir Colin Campbell,' but the greatest collection is at Taymouth, the seat of the Earl of Breadalbane. Sir Colin Campbell, the earl's ancestor, was Jamesone's first and chief patron. In a manuscript containing several portraits painted by Jamesone for Sir Colin, with reference to the history of the family, there is mention of several Jamesone's pictures also in the two colleges of Aberdeen. There is a portrait of Jamesone by himself at Cullen House; he appears to have often painted his own portrait, and he always painted himself with his hat on, which he may have done either in imitation of Rubens, or on being granted that privilege by Charles I. when he sat to him.

Though the pupil of Rubens and the companion of Vandyck, Jamesone's works have neither the finish nor richness of the former, nor the vigour of the latter; they are however painted very thinly and with much nature, but there is a sharpness in his outline which reminds of a very different school from that of Rubens. It is called, says Walpole, 'a light rate.' There are several of Jamesone's pictures also in the two colleges of Aberdeen. There is a portrait of Jamesone by himself at Cullen House; he appears to have often painted his own portrait, and he always painted himself with his hat on, which he may have done either in imitation of Rubens, or on being granted that privilege by Charles I. when he sat to him.

JAMESON, JOHN, D.D., is best known as the author of the Scottish Dictionary, but he published many other literary works, and for many years held a position in the metropolitan and provincial press. He left, also, in Edinburgh, a manuscript entitled 'Recollections of my Past Life,' a collection of his writings. He brought to the world a number of other works of the same kind, and among the most noticeable of these was the 'Memoir of the Life of the Younger Mr. Bruce,' which was published in 1798.

Forfarshire, 1798, Jan.

Minstrelsy in its session as a literary work, was brought into existence by the Rev. Robert Bruce of Garston, a young clergyman, who was ordained to the ministry of the Church in Forfarshire. He was also a friend and supporter of the Seceder movement, and was associated with Jameson in the publication of the Scottish Dictionary.

For the last quarter of a century, his time was devoted to the study of literature, and in addition to the works already mentioned, he published a number of other works, among them a 'History of the Seceders,' in two volumes, and a 'History of the Scottish Church.'

Jameson was a man of great learning and ability, and his works were widely read and admired. He was a man of wide knowledge, and was well acquainted with the literature of the world.

Jameson was a man of wide knowledge, and was well acquainted with the literature of the world.

Jameson was a man of wide knowledge, and was well acquainted with the literature of the world.
Sea, lying between 70° 49' and 71° 19' N. lat., and between 7° 20' and 8° 44' 20" W. long. It extends from south-west to north-east, and is in no place above nine in breadth; at some places it is less than two miles. On the northern extremity, where the island is widest, stands the mountain called Beerenberg. By Beerenberg, a peak rising to 6870 feet above the sea-level. It frequently shows its snow-capped summit above the clouds, and rests on a rocky mass 1800 feet high. In other parts the rocky masses appear to amount to elevations of between 1500 and 2000 feet. A large portion of the island is composed of lava and other volcanic matter, and two craters have been discovered on the eastern side; smoke and fire have been observed in these points.

Even in the beginning of August all the high lands are found covered with snow and ice, and the low lands in those valleys and deep cavities where large beds of snow have been collected, retain part of their covering to the very border of the sea. At the foot of the Beerenberg there are three very singular glaciers: they occupy recesses in the cliff where it is more than 1000 feet high, and nearly perpendicular. They are very rough on the surface, and a greenish grey colour. They present the appearance of immense casuets suddenly arrested in their progress and congealed by the power of an intense frost. Like cascades, their prominent greenish colour is answered by the white matchless patches resembling foam, which, deeply contrasted with the jet-black points of the most prominent rocks peeping through their surfaces.

The coast has several roadsheets with good anchorage in five or six bays of water, black sand, and also shingled shore; but no harbour for a ship, all the anchorages being open to the sea in an angle of at least ten points of the compass. The soundings about the island are very irregular, and the bottom generally consists of rocks or black sand. The western navigation of Jan Mayen is preferred to the eastern, as being less encumbered with ice and less subject to calms, squalls, and whirlwinds, which are often encountered in passing to the east of Beerenberg. The northern island is generally surrounded by ice in the spring of the year; but in autumn, and even in summer, the ice sometimes sets so far to the westward that it is not visible from any part of the land.

There are foxes and white bears, and perhaps also reindeer. Water-fowl are numerous, especially burgomasters, fulmars, puffins, guillemots, little auk, kittiwakes, and terns. Several estaceous animals abound, principally of the species Baluma Physalis. The vegetation is very scanty, and limited to a few species scattered widely about among the volcanic minerals. Iron has been observed at several places.

The island was discovered in 1611 by a Dutch navigator called Vos, who, to abate much fire on account of the great number of whales, which, however, afterwards retreated to other parts of the Arctic Sea. In this time (1613-1614) seven Dutch seamen wintered here, probably for the purpose of engaging in trapping a bear and sealing. They prepared a regular journal. But on the arrival of the Dutch fleet in the following June all were found dead in their huts. From the journal, however, it appeared that they had not been killed by the whale, but by their scarcity of food and want of fresh provisions. Their journal terminated on the 31st of April.

(J.A.V., An Atlas of the Arctic Regions.)

JARDYN, KAREL DE, one of the best of the Dutch landscapists, pastoral, and genre painters, and the most distinguished of N. Berghem's scholars. He was a native of Amsterdam, and lived some time in Rome, where the Flemish painters gave him the nickname of Bokkehaert (goat-beard). He died at Venice in 1678, aged about forty. There are many spirited etchings by his hand.

(Houbraken, Groote Schouburg, &c.; Bartsch, Peintres-Graveurs.)

JASIONE, a genus of plants belonging to the natural order Capparidaceae. It has a 4-leaved rotate calyx, anthers cohering at the base, a hairy trifid style, 2-celled capsule opening by a large and somewhat valvular pore at the base. There is but one British species of this genus.

J. montana has a simple root, bluntish oblong wavy leaves, and yellow flowers. The stamens are from six inches to two feet long, pliöse, simple, or branched; leafy below, bare and glabrous above, and ascend from the crown of the root. The flowers are small, in terminal bracteate heads, having a light blue color.

(Rabbing, Manuel of British Botany.)

LAVOLPUS PRISCUS, a Roman jurist, from whom there are a few curiosities in the Digest. His period is not certain. He is said to have been a successor of Caeasus Sabinus, and he succeeded to the Sabini; and some writers place him in the time of Nerva and Hadrian. He was the master of Sulpicius Julianus. It may be supposed he lived between 160 and 200 A.D. (Zonar, 40, tit. 5, 6), that Javolpus sometime held the offices of governor of Syria and Africa. He is probably the Javolpus Praecis mentioned by the younger Flinn (Ep. vi. 15), who stopped by a timely answer Sulpicius Julianus from inflicting a sentence on him. Javolpus is mentioned by Capitolinus in his Life of Antoninus Pius as one of the jurists who were the advisers of the emperor. But this would extend his life beyond probable bounds. He was also the master of Minorus, who was the master of the Edicen Perpetuum under Hadrian, could not have been one of the advisers of Antoninus Pius. According to the Florentine Index, Javolpus wrote fifteen books on Cassio, that is, Cassius Longinus, fourteen books on Epistole, and five books on Plautius. He was also the author of an Epitome of the Libri Posteriorum of Laberio; and made notes on them (Ep. 40, tit. 12, x. 42).

HENKINSON, ANTHONY, or AINVIA, P. C. S.]

JEREMIE, SIR JOHN, was born in Guernsey, August 19, 1725, and was the eldest son of the late John Jeremie, a distinguished advocate of the Royal Court of that island. At his birth, an extraordinary prodigy, for, after the commencement of his public life, he distinguished himself before the royal commissioners, sent over to Guernsey to correct certain abuses in the laws and administration of justice in that island. He was afterwards retained in many different cases, both civil and criminal, and soon acquired a high character for independence and energetic zeal in the discharge of his professional duties. On more than one occasion he was chosen to plead causes in the Privy Council, where his talents and eloquence found a larger stage for their action, and brought him before the notice of government.

In October, 1834, he was appointed to the office of Chief Justice of S. Lucia, in the West Indies. 'At the time the offer of an appointment was made to him,' he observes, in his Essays on Colonial Slavery, 'he was unacquainted with a single individual in the service of the colonial department, and his political opinions were rather opposed to the then existing government. On the question of slavery he was thoroughly indifferent; indeed, it was so remote from his usual pursuits, that he may fairly say he had never given it a thought. In the intervals of his official duties, he devoted himself to the abolition of slavery, and in this capacity, he hoped that he was not only doing a good work of charity, but was contributing to the abolition of the system.

It was under this impression that he went to the colonies, and the candid expression of his feelings on the subject of slavery, which we have quoted, must acquit him of any bias in favour of its abolition, and prove that his subsequent devotedness to the great cause of emancipation was the entire result of a conviction pressed upon him by an actual knowledge of the evils of the system. No sooner, indeed, was the slave law of 1825 promulgated, and the slave enjoyed the liberty of freely communicating with his protectors, than numerous examples of revolting cruelty, brought before him in his official capacity, produced a rapid but lasting change in his opinions. In proportion to the extent of his inquiries was the depth of his conviction that the only remedy to the evil of slavery was the gradual emancipation of the slaves. His views on this important subject are fully put forth in his 'Four Essays on Colonial Slavery,' which he published on his return to England in 1831; in them he describes the general features of the slave communities, and the beneficial effect of the ameliorations already adopted, and he proceeds to show what he believes to be the only future system. The principle by which he was actuated in publishing these essays will be seen from the following extract. 'Such then,' he observes, 'is the unanimous and uniformly formed the West Indian communities; nor can they complain that they are anonymously misgained, that they are
suggested for ameliorating the condition of the liberated slaves that, undeterred by the perils of a pestilential climate, he accepted, in October, 1840, the important office of Governor and Captain-general of Sierra Leone, in the West Indies, and he has repeatedly from the judgement-seat in the sternness of duty, with the still stern serenity before him. They are now published, neither vindictively nor in anger, but because, having availed every other method, he has acquired a personal conviction that publicity alone can lead to a thorough reformation.

In the year 1839, he was appointed to the office of Procurer and Advocate-General of the Mauritius. He had there to contend not only against objections of a personal nature, arising from his known opinions on the slave question, but against national and deep-rooted antipathies of a population almost entirely of French origin, and strongly attached to French institutions. The office, moreover, which he held presented peculiar difficulties to one who was determined conscientiously to perform the work imposed. It was ever so as to assimilate it to that of an English attorney-general; they are only so far similar that they both fulfil the duties of a public prosecutor. The procurer-general, among the French, is something very magistrate, and has to enforce the decrees of the courts, and he has under his control the police force of the country. When the disaffected party at the Mauritius heard of Mr. Jeremie's appointment to an office which, we believe, had been recommended to the political committee to the legal system of democracy, they broke out into an almost open rebellion. On his arrival before Port Louis, so great was the fear entertained for his personal safety by the British authorities, that all access to the shore was cut off to the admiral, who had petitioned the governor altogether to prevent his landing: their request being refused, after a detention of two days he went on shore, under the protection of the whole naval and military force in the island, and on the same day was sworn into office, at a meeting of the legislative council.

The many scenes of violence which ensued are fully detailed in a pamphlet entitled 'Recent Events at the Mauritius,' which he published in vindication of his conduct. It is but necessary to mention that the governor thought it advisable, for the security of the public peace, to order him to return to England, believing he had previously declined to do so, except a written assurance was given him to that effect. On his arrival in London he immediately reported himself to the colonial office, adding, that he was ready to resume his journey back to the Mauritius at an hour's notice. His request, though delayed, was granted, and his return to that island preceded by an additional military force. The feelings, however, originally excited against him did not easily subside, and his residence there, which terminated in 1836, was embittered by a series of painful events, affecting his own striking language, and character. 'Within three years,' to use his own words, 'he had travelled fifty thousand miles, encountered the Asimain on shore and the pirate at sea; for ten years had it been his fate to face, in the service of the Mauritius, the storm and sunshine, and whether from the ocean, from climate, or from the hand of man.'

In the year 1836, he was appointed to the office of puisne justice of the Supreme Court of Ceylon, and during the same year he received a gratifying proof that his devoted zeal in behalf of emancipation had been fully estimated by the British public. A valuable plate of plate was presented him by the Anti-Slavery Society; the inscription upon it testifying that 'by his disinterested, able, and energetic exertions in most critical and painful situations, both at home and abroad, negro freedom had been largely advanced, and the negro character raised to its just and natural public estimation.'

His residence during four years at Ceylon was the only tranquil period of his eventful life. Early in the year 1840, he published a 'Letter on Negro Emancipation, and African Civilisation,' addressed to Sir T. F. Buxton. In it he describes the present, and shows what he considers will be the future effects of emancipation in the colonies, and gives a short outline of the progress which has been in the process of development. Mr. Jeremie says, 'we must look for the regeneration of Africa. To a reduct of the west upon the east, in moderate numbers, and managed with caution, must we look for the civilisation of the continent.'

It was to carry into effect the measures which had been
JOHN, KING OF SWEDEN. [CHARLES XIV.]

JOHNSON, DR. ARTHUR, the fifth son of an ancient family possessing estates in Aberdeenshire, was born in that county in 1687. At an early age he went abroad for medical education: and the degree of Doctor in Medicine was conferred on him at Padua in 1710. He traveled in various parts of the continent, and resided for twenty years in France, marrying twice in the course of that period. He returned to his native country before the year 1736, and was soon after wards appointed physician to Charles 1, probably through the influence of Land. After this appointment he must have resided chiefly in the neighbourhood of the court. In 1741 he died at Oxford, while on a visit to a daughter married there. Johnson's name is preserved in the memory of scholars by his Latin verses. He was the most extensive contributor, and is not unusually called the editor, of Sir John Scott's collection of Latin poems, the 'Dellitae Poetarum Scoitarum hujus Evi Illustrium,' Amsterdam, 1607, 2 vols. 12mo.; and besides several other volumes of compositions in Latin verse, he was bold enough to measure lines with Buchanan in a version of the Psalms, 'Paraphrases Poeticae (Scottis amicis abac. Mus.,' Edinburgh, 1667, 2 vols. 8vo. This ambitious attempt led, many years afterwards, to a protracted controversy on the merits of the rival versions. The history of the dispute is related, and Johnson's views of the subject are fully exposed in Dr. Moxon's 'Lives of Scottish Writers,' 1839, 3 vols. 8vo. It is enough here to say, that Johnson's high rank among modern writers of Latin poetry is universally admitted: and that, although in Scotland his poems have usually been estimated much below Buchanan's, the justice of this sentence has been questioned by critics of authority, of whom Mr. Halkam is one.

JOHNY (French, Mémorial) is the art of joining in the making of buildings, for making articles of furniture, and for numerous purposes requiring greater neatness of workmanship than the operations of the carpenter. [Carpenter, F. C., p. 392.] As carpentry is the practice of making, erecting, and working in wood, and a joiner is a person versed in this art, so the term 'joinery' is applied to the use of joints in the frames of buildings, to the making of articles of furniture, and to the construction of various types of objects in wood. The term 'joinery' is used to describe the work of a joiner, who is a person who works in wood, and who is usually employed in the construction of buildings, for making articles of furniture, and for numerous purposes requiring greater neatness of workmanship than the operations of the carpenter.

JOHNSON, Dr. Arthur. Life of. See life of John, King of Sweden.)

JOHNSTON, JOANNE. Munich, 1680. The account of the JODE, printed in Munich, 1680, was the first edition of the Psalms, and was issued in a large folio, with a dedication to the Elect of his own paper. The elder, the son of Gerard de Jode, also an engraver, was born in 1570. He was the pupil of Goltius, and worked in Italy and at Paris, and died at Antwerp in 1634.

De Jode engraved many plates in a good style, among them the remarkable picture of the Last Judgment, by Cranach, and the two St. John's, making altogether about thirteen square feet, each four way: it is one of the largest prints in existence.

The younger de Jode, or Petrus de Jode, Junior, as he signed half of his prints, was born Antwerp in 1606, and was instructed in engraving by his father, whom he soon surpassed in execution, especially in the nude, and equalled in correctness of drawing. He worked with his father in Paris. His works after Vanderlynck, his best works, among them are his own, and those of Jordaens, Pouchet, Suellina, De Coster, and others, printers of Antwerp. He executed also some good prints after Rubens. The date of his death is not known.

ARNOLE DE JODE was the son of the younger Pieter, and was born at Antwerp about 1636. He is said to have been in London in 1687, and then to have engraved a print after the picture by Correggio, which belonged to Charles 1., and is now in the National Gallery. Scarcely anything is known of him personally: as an engraver he was inferior to his father and grandfather.

[Manuscript du Roy des Géants; Hubert, Manuel des Amateurs, &c.]

He returned to his native country before the year 1636, and was soon after wards appointed physician to Charles I., probably through the influence of Land. After this appointment he must have resided chiefly in the neighbourhood of the court. In 1641 he died at Oxford, while on a visit to a daughter married there. Johnson's name is preserved in the memory of scholars by his Latin verses. He was the most extensive contributor, and is not unusually called the editor, of Sir John Scott's collection of Latin poems, the 'Dellitae Poetarum Scoitarum hujus Evi Illustrium,' Amsterdam, 1607, 2 vols. 12mo.; and besides several other volumes of compositions in Latin verse, he was bold enough to measure lines with Buchanan in a version of the Psalms, 'Paraphrases Poeticae (Scottis amicis abac. Mus.,' Edinburgh, 1667, 2 vols. 8vo. This ambitious attempt led, many years afterwards, to a protracted controversy on the merits of the rival versions. The history of the dispute is related, and Johnson's views of the subject are fully exposed in Dr. Moxon's 'Lives of Scottish Writers,' 1839, 3 vols. 8vo. It is enough here to say, that Johnson's high rank among modern writers of Latin poetry is universally admitted: and that, although in Scotland his poems have usually been estimated much below Buchanan's, the justice of this sentence has been questioned by critics of authority, of whom Mr. Halkam is one. [Carpenter, F. C., p. 392.]

JOHNY (French, Mémorial) is the art of joining in the making of buildings, for making articles of furniture, and for numerous purposes requiring greater neatness of workmanship than the operations of the carpenter. [Carpenter, F. C., p. 392.] As carpentry is the practice of making, erecting, and working in wood, and a joiner is a person versed in this art, so the term 'joinery' is applied to the use of joints in the frames of buildings, to the making of articles of furniture, and to the construction of various types of objects in wood. The term 'joinery' is used to describe the work of a joiner, who is a person who works in wood, and who is usually employed in the construction of buildings, for making articles of furniture, and for numerous purposes requiring greater neatness of workmanship than the operations of the carpenter.
practice the French joiners are very inferior to our own.

Their work, he says, 'is rough, slovenly, and often clumsy, and the look is that of a dirt unskilful hand.' 

On the other hand, the officers of the London Society, in a recent report, speak of the work of the Parisian colleague as 'neatness, and accuracy which is so common to every part of the works of an English joiner, is scarcely to be found in the works of a French one.' 'The little correspondence,' he adds, 'which exists between the manufactory and the forest, leads us to think that their theoretical knowledge is confined to architects, engineers, &c., instead of being diffused among workmen, as it is in this country.'

In the second place, is of primary importance to know the peculiar properties of the material that is used. This subject is briefly noticed under Carpenter, P. C. S., p. 292, and some information bearing upon it is given in Experiments, P. C., p. 120, is an explanation, illustrated by sectional diagrams, of the manner in which woody matter is formed, and of the arrangement of the component parts of the trunk of a tree.

Tredgold gives much information relative to various kinds of wood in his 'Elementary Principles of Carpenter,' and, in his treatise on joinery in the 'Encyclopædia Britannica,' he gives the results of some important experiments on those peculiar properties of wood which lead to its warping and cracking.

Of these the first in order was made by T. A. Knight, Esq., and communicated by him to the Royal Society in 1801 and 1817; and they appear to be opposed to some generally received opinions of the kind of timber best suited to the subject, printed in the ninety-first volume of the 'Philosophical Transactions' (p. 344, &c.). Mr. Knight observes, 'that there is in every kind of wood some workmen call its grain, consisting of the inner and more shrinkable portion of the wood, itself and its pith, &c.' The former, he explains, consists of those concentric circles which mark the annual increase of the tree; and the latter is composed of very thin laminae, diverging in very irregular veins from the medullary line, the parts being so near, that close adhesion to each other at any time, and less during the spring and summer than in the autumn and winter, whereby the greater brittleness of wood in the former season. His observations on this property of English oak, but they are, he says, more or less applicable to every other kind of wood, the wood of exogenous plants only, of course, being included in this remark.

The truth of his observations is illustrated by the fact that in drying whole trunks it is impossible to prevent the wood from splitting more or less, the cracks being in all cases directed towards the centre, thus indicating that the wood shrinks in a greater ratio in the direction of the circumference of the trunk than in the direction of its diameter, and that the radiating or diverging laminae of what Mr. Knight styles the true or silver grain will readily separate from each other, whereas the wood of the true trunk, as Mr. Knight observes, 'is usual to cut it as much as possible, into what are called quarter-boards, which are so named because the tree is first cut into quarters. In a perfect board of this kind, the latter will consist in part of the outer circle on which the tree most readily divides when cloven; in this case the lamina of the silver grain lie parallel with the surface of the board, and a board thus cut, when properly laid in the floor, is rarely or never seen to devote from its true horizontal position.'

An American machine for cutting up trunks so that all the boards produced may possess this quality is noticed under Saw-Mill, P. C., p. 481. 'If, on the contrary, to resume Mr. Knight's observations, one be sawed across the silver grain, it will, during many years, be incapable of bearing changes of temperature and of moisture without becoming warped; nor will the strength of numerous nails be sufficient entirely to prevent the inconvenience therein arising. This surface of a board of this kind which grew nearest the centre of the tree will always show a tendency to become convex, and the opposite one concave, if placed in a situation where both two edges, being abutted against the floor from the same tree; and the latter consequently contract more longitudinally in drying than the former, and the edge of every board (that has been cut with surfaces nearly parallel with the line of the converging cellular processes) which lay nearest the medulla in the tree will therefore in drying become convex, whilst the opposite edge will become concave.'

From these remarks it may be presumed that while, where flatness of surface is the principal object, a piece of wood cut like BD, Fig. 1, is preferable to one cut like AC, the latter would be preferable where the permanent straightness of the edges is of the greatest importance, because the fibres near its two edges, being relatively distant from the pith or medulla, will shrink equally, while in BD those at the edge B will contract more than those at the edge D.

By paying due regard to such circumstances in the selection of wood, the joiner may arrive at a great degree, evade the inconvenience arising from irregular variations in the dimensions of his material. As an illustration of the application of such knowledge we may refer to the method described in Dods's 'British Manufactures,' series 4., p. 211, in Knight's 'Weekly Volume,' as occasionally adopted in the formation of large deal table-tops, for veneering with mahogany or rosewood. Owing to their great weight, in various circumstances, such boards or slabs are peculiarly liable to warping but the tendency is guarded against by selecting those as free
as possible from knots, and sawing them longitudinally into pieces four inches or four inches and a half wide. These are glued together side by side, an edge which has been nearest the heart of the tree being joined to an outside edge. With the glue thoroughly set, the whole compound board, thus produced is again cut up into slits, by sawing it longitudinally midway between the joints, and these slits are rejoined, with a further change in the order of placing the pieces. The result of all this is that the pieces are not more than two inches wide, so arranged as mutually to counteract any inclination to warping. A due regard to the laws of warping and shrinkage is also very necessary in the construction of large doors for drawer decorations, which are commonly built up, and were, of several distinct pieces of wood. In making wooden columns, for example, several pieces must be fitted together to form a hollow cylinder, in preference to using one large post; or, where large posts are used, they must, if appearance is to be regarded, be surrounded by a number of narrow pieces. Small columns may be made of a single piece, and prevented from splitting by boring a large hole down their axis.

The original shrinkage of wood in drying is not however the only change of dimension to be provided for, since, from its hygroscopic properties, changes in the state of the atmosphere occasion even old and seasoned wood to vary in size from time to time. Of this we have a familiar illustration in the fact that doors, especially garden doors, which open and shut with facility in dry weather, frequently swell so as to become impossible to a housekeeper of the atmosphere. From experiments made by M. Rondelet, quoted by Tredgold, it appears that in wood of a mean degree of dryness the extent of contraction and expansion produced by the usual changes in the state of the atmosphere was, in fir-wood, from 4\(\frac{1}{10}\) to 4\(\frac{1}{2}\) part of its width, and in oak, from 4\(\frac{1}{10}\) to 4\(\frac{1}{5}\) part of its width, showing a mean variation equal to 4\(\frac{1}{2}\) part of the width in fir, and 4\(\frac{1}{5}\) part of the width in oak. At this mean rate of variation the difference of width produced by the above cause alone in a fir board about 12\(\frac{1}{2}\) inches wide would be \(\frac{1}{8}\) of an inch, an amount abundantly sufficient to cause the board to split or crack, if it were fixed immovably at both edges.

For the above reasons it is always necessary to insert panellings in the framework in which they are mounted, in such a manner as to allow free motion at one or both edges. An ordinary framed door, such as that represented under Doors, P. C., p. 86, affords a good example of panellled work, and one in which this peculiarity may be readily observed. In this kind of door the styles, marked 2, 2, in the cut referred to, the rails, marked 4, 4, and the mouldings (or, as they are frequently called by workmen, the moldings), marked 6, 6, 6, constitute a strong framing of thick but comparatively narrow pieces of wood, the rectangular openings of which, marked 1, 1, 1, 1, and 3, 3, 3, 3, would have been cut in a paneled door of the thickness of the framing. The panelling are slid, before the framing is completely put together, into grooves, ploughed or cut, about half an inch deep, in the inner edges of the framing, which grooves these are made to fit with sufficient accuracy to prevent shaking or rattling, yet not so tight as to prevent their sliding a little in the grooves, as the panel shrinks or expands. The usual practice is to fit them just so tight that a little force applied to the edge of the panel with the palm of the hand, is sufficient to drive it into its place. In new houses it may often be perceived, by the appearance of the paint towards the sides, or rather edges, of the panelling and windows, that, even when not more than nine or ten inches wide, they have shrunk at least one-eighth of an inch since the completion of the painting, notwithstanding the care taken to season them previously; and the shrinkage, if properly made with sufficient accuracy, it would be found that the amount of shrinkage appears to be greater or less according to the state of the atmosphere. The addition of glue or nails to hold the panel in its place would occasion a similar shrinkage, but if it be made with sufficient accuracy, it would be found that the amount of shrinkage appears to be greater or less according to the state of the atmosphere. The addition of glue or nails to hold the panel in its place would occasion a similar shrinkage, but if it be made with sufficient accuracy, it would be found that the amount of shrinkage appears to be greater or less according to the state of the atmosphere. The addition of glue or nails to hold the panel in its place would occasion a similar shrinkage, but if it be made with sufficient accuracy, it would be found that the amount of shrinkage appears to be greater or less according to the state of the atmosphere.

In some cases partitions, wainscottings, and other pieces of joiner's work are framed and panelled in the same way as ordinary doors, the panels themselves being, when too wide to be cut out of a single board, composed of two or more pieces of wood, the joints of which are by no means free from warping. However, that such panels should never be made more than fifteen inches wide and four feet deep, and not so large if it can be avoided. A similar construction is also adopted in superior doors for the frame of the panelling, and in the cases, &c., as the plan is more effectual than any other for the exclusion of dust. By dividing the width of the back into two or more portions, it reduces the amount of possible shrinkage at any one joint; and if the panels be made to enter the grooves of the framing only a quarter of an inch at each side, each panel may shrink nearly half an inch without producing any aperture between the panel and the framing. A simpler but less effectual mode of attaining the same object, which is often adopted for the backs of furniture, and for some other purposes in which an extended surface of boarding, is required at less cost than is involved in framing and paneling, is to fix a series of narrow boards side by side, securing them with a few nails only, without glue, in order that they may retain as much freedom of motion as possible; and rebating the adjoining edge, as shown at a, a, Fig. 2. By this arrangement a considerable amount of shrinkage may take place without producing any opening between the adjoining boards, and, if the nails be not fixed too near their edges, sufficient play may be allowed to prevent the wood from cracking.

The appearance of such boarding may be improved by forming a head with a moulding-plane along one edge of each board on the visible side, as at b, b, Fig. 2, because by that means the open joint is in some degree masked by the firn or wide groove on the opposite side of the boarding. The same means of avoiding the disfigurement of the opening joint is adopted in some doors and shutters which are framed and panelled in the usual manner, but in which the panels are made two-thirds instead of one-third of the thickness of the framing, and are therefore cut out to obtain the thickness of an ordinary panel, and the rebated portion alone is inserted in the grooves of the framing, while the unreduced portion of the panel is brought flush or even with the surface of the framing. This mode of construction is often adopted for external doors, as it allows them to be made strong without any great thickness of framing. At c, c, Fig. 3, is shown another mode of jointing boards side by side, which is called match-paneling, and is applicable to doors, or stuff, or of exceeding half an inch in thickness. This plan is frequently adopted for the kind of inferior doors called lensed doors, which, to avoid the expense of framing, are made of narrow boards placed side by side, and held together by transverse pieces called ledges or battens, to which each of the boards is nailed. The joint, as shown in the cut, where it is represented as masked by a bead, consists of a tongue cut in the end of one of the boards, receiving a projecting tongue formed on the edge of the adjoining one. Planes called match-planes, made in pairs, one for forming the groove and the other for forming the tongue, are made to facilitate the fitting of the joints, and are occasionally do with a noise sufficiently indicative of the irresistible force with which the change of dimension takes place. In superior doors the edge of the framing and the face of the panel is occupied by a moulding, put in with mortised joints, which are explained below; in such a case, the use of the tongue is not necessary, and the joints may be made to enter the framing only a quarter of an inch at the edges, without touching the panels. In bad work they are often driven carelessly into both, and the almost inevitable consequence is that the panels crack, in consequence of their freedom of motion being interfered with.

As indicated by its name, a very important department of the art of joinery is the formation of strong and accurate
The joints hitherto noticed are not intended so much for holding together the pieces of wood united by them, that objects be held perfectly rigid, as for the purpose of forming a surface, or making the wood serve as a frame for various purposes. By the framing in works of joinery depends wholly upon the joints.

The simplest mode of uniting two pieces of wood is to cut the meeting surfaces so as to fit each other accurately, and to cement them together with glue. (p. 278.)

When the glue is good and properly applied a glued joint is surprisingly strong—stronger, indeed, in some cases, than the wood itself; if, for example, two boards be glued edge to edge, as for forming a panel, the wood will break, if sufficient force be applied, without the joint giving way. In forming such a joint the adjoining edges must be planed perfectly straight and smooth, which may be readily done by the use of the simple contrivance called a shooting-board, which is a flat board with a perfectly straight edge, and with a cross-piece fitted on one end at right angles with that edge. The cross-piece being on the board, the panel is laid down upon it, with its end against the cross-piece, and the plane, which is laid on its side on the bench, is rapidly slid or shot along, being guided by the edge of the shooting-board, and so fitted to the edge of the panel, being thus made true, are smeared with hot glue, and one edge rubbed backwards and forwards a few times over the other, to distribute the fluid glue equally, to force it into the pores of the wood, and to squeeze all that is superfluous out of the joint.

This done, the boards should be set aside until the glue is perfectly set. To prevent the possibility of any strain which might tend to open the joint while the glue is soft, it is well in such cases to fix the board edge ways, so that the weight of the uppermost piece may tend to keep the joint close.

In many other kinds of joint the hold of glue is less perfect, and a greater impossibility of applying the rubbing-downs necessary for the purpose above mentioned; and in such cases it is necessary to secure the parts united by it, in their places by screwing the article up in an iron cramp, by weighting, or by wedging. From a carefully conducted experiment by Mr. B. Bevan, of which, as well as of his experiments on nails, which are referred to below, an account is given in the article 'Adhesion' in Herbart's 'Engineer's and Mechanic's Experiments and Appendix on the Theory of Machinery and Mechanic's Magazine,' it appears that the adhesion of glue, under favourable circumstances, is equal to a force of at least 715 lbs. per square inch. In the experiment referred to a frame was formed of two pieces of beech, each four inches in thickness, and each piece was fitted into a rectangular box, the sides of which were formed of two separate cylinders of dry ash-wood, the ends of which presented a surface equal to 1·76 square inch, and which were glued together end to end, and allowed twenty-four hours to set. The box was then put into a horizontal position, three minutes before the joint gave way; and it was found, on examining the separated surfaces, that the glue was very thin, and had not entirely covered the surface. The cohesive strength of the glue appears therefore in this experiment to have been rather more than 715 lbs. per square inch, while the cohesive strength of the wood thus united, in a lateral direction, was found to be only 659 lbs., thus showing that, if the joint had been between the sides instead of at the ends of the pieces of wood, the wood would have gone way before the joint. In this, however, the glue was newly made, and dried very fast; while in some former experiments, made in the winter season, with glue which had been frequently made, with occasional additions of glue and water, the cohesive force indicated was only from 350 lbs. to 500 lbs. per square inch. In all these experiments, Mr. Bevan found the cohesive force of solid glue to be equal to 4000 lbs. per square inch, from which it may be inferred that its application as a cement is capable of such improvement as to show a more active action, and a greater thickness of the joint than in the experiment above described.

Glue that has been made a long time and kept in store is found to possess greater tenacity than newly-made glue; and for the use of the joiner pale-colored glue is preferred, as it is paler new and has a less apparent joints. Owing to the use of a darker material, and the less frequent employment, at 2½ lbs. in joints exposed to the

eyes, the colour of his glue is a matter of less importance to the cabinet-maker.

Next to the formation of joints by the simple interposition of glue between the meeting surfaces, we may note the use of nails or pins of metal, so inserted as to enter both pieces, and to bind them together with a force equal to that required for their extraction. Mr. Bevan's experiments on the adhesion of nails, and of screws, which are often used in the various kinds of nails, driven into dry Christiana deal, at right angles with the grain of the wood—

The amount of power required to force a sixpenny nail, of the dimensions above given, into Christiana deal, by simple pressure, which affords the most accurate test of the resistance to be overcome, when working with a single inch and a half of deal, is—

One quarter of an inch, a pressure of 24 lbs.
Half an inch                         76 lbs.
One inch                              235 lbs.
One inch and a half                   490 lbs.
Two inches                            650 lbs.

In the above experiments, it must be remembered, the nails were driven transversely, or across the grain. The same nails, driven endways, or longitudinally, in the same wood, required a force of only 87 lbs. to extract them from a depth of one inch, and 267 lbs. from a depth of two inches; showing that a nail driven endways into deal has rather less than one-third the adhesion that it has when driven across the grain. In dry elm the hold of the same kind of nail was found to be greater than in deal in both directions, but especially when driven along the grain; the force required to extract it from a depth of one inch, when driven transversely, was 287 lbs., and when driven longitudinally 257 lbs., the relative adhesion in the two directions being in this case rather less than as 3 to 4, whereas in deal it was more than 2 to 1. Experiments with the same kind of nail, driven also to the depth of one inch (transversely, we presume) into dry oak, showed that the force required for extraction was 507 lbs.; in dry beech, 687 lbs.; and in green sycamore, 312 lbs. Mr. Bevan's experiments on nails, and screws, and the effects of different grains, and modes of finishing, are referred to in the 'Philosophical Magazine,' vol. xxii. p. 168, appear to have been made with wrought nails, which, for the ordinary purposes of the carpenter and joiner, have been in a great measure superseded by wrought nails driven directly through from thin sheet metal, and subsequently headed by a separate machine. Such nails are cheaper than wrought nails, and, owing to their greater accuracy of form, their sectional form being a perfect rectangle, with sharp defined angles, they are better held in the wood. They are stronger than wrought nails; but, being softer and more easily bent, they are not adapted for using with hard woods. The simplest method of forming an angular joint, to be held together either by glue, or by nails or screws, or by a combination of gluing with nailing or screwing, is by the arrangement shown at a, Fig. 5, where, however, if nailed, can only be nailed in one direction. For rough work such a joint may do very well, although it is unsightly in consequence of showing the end of the grain of one of the members of the joint, and of the liability of the joint to a little shrinkage and warping. The appearance of such a joint may be in some measure improved by the introduction of a small bead on the shutting piece, as at b, Fig. 5, or, by converting the whole joint into a shell-joint. Bevelled edge, as at c, Fig. 5, a plan which is often adopted, with very good effect, in the interior fittings of a house. The kind of joint marked at Fig. 5, which is called a shell-joint, is no better than the other; it is merely more or less fine, for the joint is nowhere exposed to view, and it allows nailing in both directions; but it is not so secure, and, owing to the
The tendency of the inclined faces to slip upon each other, it is difficult to form it with accuracy. It is the joint used for the angles of picture-frames, and for many other purposes in which the joint is exposed to view in the same manner; and in such cases the strength of the joint is often increased by inserting, in a saw-cut made for the purpose in a sloping direction, a thin slip or key of hard wood in the direction indicated by the dotted lines. This key is inserted with glue, and when that is dry, the superfluous corners are cut off. At e, Fig. 3, is shown a mitred joint at an obtuse angle, to show that this form of joint is applicable to any angle, the plane of the joint being in all cases made to bisect the angle. To facilitate the accurate formation of mitred joints, joiners employ a contrivance called a mitre-box, by which they are enabled to saw and plane, or smooth, the inclined faces exactly to the required angle. The last joint represented in Fig. 3, that marked f, is a combination of the overlapping with the mitred joint, much nester, where the angle alone is visible, than the former, and stronger than the latter, to which it may be nailed both ways.

Fig. 4 illustrates an arrangement almost too simple to need explanation, by which the strength of a nailed joint of the over-lap kind may, with very little extra trouble, be greatly increased. Simple as it is, however, it is very rarely practised in this country, and, indeed, has never been seen by the writer existing in tobacco-cheese or packing-cases from America. For nester purposes it might be worth while to divide each joint into four or more portions, instead of two only, as in the cut, by which means the tendency of the joint to open by the warping of the wood, or in consequence of external violence, would be still further resisted, owing to the more frequent changes in the direction of the nails.

In all the angular joints above noticed, the two pieces of wood which form the members of the joint are held together by the glue, nails, or screws applied to connect them; but in the higher operations of the joiner and cabinet maker, the wood is so cut as in some degree to hold the construction together independently of the writer. In the joints shown in Fig. 5, for example, where a represents a joint adapted for external angles, and b a joint for internal angles, such as those of the skirtings of a room, the form of the joint alone would hold it together, irrespective of any fastenings. The same object is attained far more perfectly by the various modes of dovetailing, the simplest of which is illustrated by Fig. 6, in which a is present, in isometric perspective, a portion of two boards, such as two sides of a box, or the back and one side of a drawer, cut ready for fixing together by an ordinary dovetailed joint, and c shows the joint as it appears when fitted together. It will be evident that, when thus united, the wedge-shaped projections from the end of the piece a (from the transverse sectional form of which, somewhat resembling that of a dove's tail, the joint takes its name) must powerfully resist any strain tending to separate the joint, unless that strain happen to be exerted precisely in one direction; while the accu-

rate fit of the parts, aided by the glue, and in some cases by nails or screws, renders the joint so strong even in that direction that, if properly made, the wood will sooner break than separate at the joint. The small dovetail-shaped projections in the piece a are called pins, and the openings cut in the end of b to receive them, holes. When the boards which constitute the members of a long dovetailed joint are composed of two or more pieces glued together at the edges, it is well so to arrange the dovetailing that the glue is not arranged corresponding with a in the cut, shall fail in one of the pins, and not all of them, and if in the piece a in one of the intervening solid spaces between the holes, and not in the hole itself; because by such an arrangement the driving up of the dovetail tends to hold the glued joint together, while it might otherwise tend to split it open. In connecting the front of a drawer with its sides, it is desirable to conceal the joint entirely on the front face. This is done by the kind of joint shown in Fig. 7, which is termed a dovetail blind of one eye.

In the piece forming the front of the drawer is made thicker than the sides, and the pins, which are formed on the front piece, are made only as large as if were of the same thickness as the side, and the intervening spaces are not cut through the extra thickness of the wood. Similar to this is the dovetail blind of both eyes, or mitred dovetail, in which both piece are of equal thickness, and the pin-holes, as well as the pins, are stopped about one-eighth or three-sixteenths of an inch from the outer or visible surface of the wood, the extra thickness of the wood thus left uncut being mitred; so that the joint is very secure, but the means by which it is rendered so are completely invisible. Such a joint of course requires very accurate workmanship, to enable all the parts to fit closely without being so tight in any part as to need injurious force in knocking it into its proper position. The only other kind of joint that claims notice here is the mortise and tenon, which is the kind of joint usually employed for connecting the several members of the framing of a door or similar piece of panelled work, as well as for many other purposes. A mortise is a deep and narrow groove cut in one member of the framing to receive a corresponding projection called a tenon, or, improperly, a tenant, formed on the end of another member of the framing which abuts upon it, usually at right angles. Tredgold recommends that the thickness of a tenon, and consequently the width of the mortise to receive it, should be about one-fourth of the thickness of the framing, and that the width of the tenon should never be greater than five times its thickness. A more general rule, however, is to make the tenon one-third the thickness of that part of the framing which it is to enter. When the members of the framing are wide, the tenon is divided by the intervening space into two parts, by which the necessity for weakening the frame by very long mortises is avoided. In Fig. 8, a represents a divided tenon of this kind, and b is what is termed a double tenon, which is sometimes used in very thick framing, especially in the framing of doors which are to receive mortise locks, or locks inserted in the thickness of the door, in which case the lock is placed in the interval between the two tenons. In some cases, where a single tenon is used in thick framing, a small projection called a cross or feather-tenon is formed on each side of it like a very short tenon, as in c. Fig. 8 shallow grooves or mortises being cut on each side of the principal mortise to receive them.
Clamping is an expedient resorted to by the joiner when he wishes to secure a broad board, whether formed of a single piece, or of two or more glued together at their edges (in such a case, if the wood be thick, dored, or pins inserted half-way into each of the adjoining pieces, may be used to aid the glue), from liability to warping. It consists in fitting on to each end a transverse piece, as at Fig. 8, the grain of which runs at right angles with that of the board. The connection between the board and the clamp is effected by a tongue formed on the end of the board, visible at the edge in the cut, and entering a groove ploughed in the edge of the clamp. In addition to this tongue, which extends across the whole width of the board, two or three tenons, which may or may not pass completely through to the external edge of the clamp, are frequently formed on the end of the board, in which case the joint is termed a mortise clamp; and in some cases where special neatness is required the ends of the clamp are mitered into the board, as at e, Fig. 8, which is called a miter clamp, and in which both the tongue and the tenons, if tenons are used, may be made invisible.

Where it is necessary to curve boards by softening them, by boring or steaming, and forcing them into the required shape (in which they are retained by gluing blocks underneath them and by other means), upon a saddle or mould, Tredgold observes that the process may be improved by saturating the convex side, while the wood is still confined to the mould, with strong glue, which may dry and harden in the extended pores, and thereby tend to keep the wood in the required shape when it is removed from the mould.

The plan of this article does not admit of much more than a passing reference to the large subject of geometry as applied to the joiner's art; a subject which is treated at great length in the practical treatises of Nichol and Tredgold; nor does it allow of any detailed explanation of the modes of executing the various departments of his work, which, together with a full account of the tools employed, may be found in Nicholson's 'Architectural Dictionary.'

The Joiner and Cabinet-maker, alluded to near the commencement of this article, will be found an admirable preparative for more expensive works: explaining, as it does, by a few familiar examples, in terms easy to be understood, most of the ordinary operations of the joiner, and some of those of the cabinet-maker. Of some of the principal tools used in joinery account are given under Saw, P. C., p. 476; Domino Instruments, P. C. S., p. 225; and Beyer, P. C. S., p. 192.

Of the other tools commonly employed, planes, of which a great number adapted for different uses are required, are the most important. An ordinary plane may be described as a broad and very sharp chisel mounted in a large block of wood in such a manner that it is always kept at a certain angle (varying according to the purpose to which it is to be applied, but commonly about 45°) with the face of the stock, which, by sliding along the board to which the plane is applied, keeps the blade always in the right position for cutting, and prevents it from digging too deep into the wood. The weight and size of the stock also enable the workman to apply the tool with greater effect and steadiness than he could a chisel held in the hand. The degree of projection of the blade from the face of the plane is capable of regulation, and the blade is held in its required position, by a wedge, which may be loosened and the blade caused to rise a little into the stock in case it should become too prominent, or technically, too proud, by striking the heel or hinder end of the stock with a hammer, or by striking in like manner on the upper surface of the front end of the stock. In planing a board to a smooth surface the work-

man commonly uses three planes: first, a coarse one, which takes off thick shavings, called a jack-plane; then one adapted for taking off very thin shavings and having a very long stock, called a try-plane. The author of 'Joiner and Cabinet-maker' thinks that this name means trueing plane; the object of the instrument being to make the surface perfectly flat or true; but the ordinary name is still more applicable, since the workman when using this plane is continually trying where, by any undue prominence in the wood, he can take off a shaving; the length and straightness of the stock, with the angle of the face, permit the tool to work as with a straight-edge, prevent the plane from bitering or cutting where the board is hollow. So soon as the workman finds that he can take a continuous shaving off the whole length of the board with the plane he knows that the face is rendered sufficiently flat. The third plane used for ordinary work is a small short-stocked plane, called a smoothing plane, adapted for application in various directions to parts in which the grain may run irregular, and for planing up small parts of the work for which the other planes are unsuitable owing to their large size. For such operations as rebating, grooving, or ploughing, and cutting beads and mouldings, other kinds of planes are used, in which both the cutting edges of the blades and the faces of the stocks are so formed as to be exact counterparts of the shape of the rebate, groove, head or moulding required. In many planes of this character, which have an immense amount of work, both in the making and using, the joiner to perform work which even a skilful carpenter could not do so well by hand in ten times the time required with the use of the plane, the blade or irons is so fixed as to cross the face of the stock obliquely, that it may the better clear itself of shavings.

In planing a piece of deal or any similar soft wood, it is necessary to avoid meeting the grain, which would cause the plane to stick; and when this inconvenience is felt, it may almost always be avoided by turning the wood, and planing in the opposite direction. In planing mahogany and some other hard woods, it is more difficult to avoid meeting the grain, as it will not be found very conveniently the part of the board and another way in another. 'To remedy this inconvenience,' observes the author of 'The Joiner and Cabinet-maker,' 'the cabinet-makers' planes are furnished with a double iron; that is, an iron with a flat dull edge is screwed on the face of the cutting-iron so as to prevent the shavings chipping up against the grain.' The more cross-grained the wood is, he adds, 'the closer does the cabinet-maker bring down the dull iron towards the edge of the sharp one, and the finer are his shavings in consequence. The joiner's try-plane and smoothing-plane, if not his jack also, are likewise furnished with these double irons to be ready to use with hard and cross-grained woods; but when he met a truly cross-grained deal, he keeps the dull iron at a good distance, perhaps an eighth of an inch, from the cutting edge, so that the shaving comes off without touching it.' The cabinet-makers' planes are made of a tapering iron, for the better holding of the joint; and among the planes peculiar to his business is the tooling-plane, which has a nearly vertical blade with a notched or serrated edge, for the purpose of levelling the iron. It is used principally for roughening the surfaces of veneers and of the wood upon which they are laid, to give a better hold to the glue.

Of turning, though a totally distinct occupation is an essential adjunct to the art of cabinet-making, an account is given under Turning, P. C., p. 418; and veneering, which is an important branch of the cabinet-maker's business, is briefly noticed under Veneering, P. C., p. 206. The last-mentioned process, as applied to the large surface of the top of a chest of drawers, is minutely described in the 'Joiner and Cabinet-maker,' in which work, as well as in the fourth volume of Dodd and Mitchell's Manuscript, in the previous column, details are also given respecting polishing with linseed oil (called furniture oil, when coloured dark to match the mahogany, to which it imparts a darker hue); beeswax and turpentine, especially French, as well as lamp black, which is usually made of gun-shell, gum-seedlac, and Venice turpentine, mixed in various proportions and dissolved in spirits of wine; but as those matters do not, strictly speaking, belong to the art of joinery, an incidental reference to them in this place is sufficient.

Jones, John, LL.D., was born in the parish of Llandin-egat, in Caernarthenshire, where his father was a respectable farmer. He was educated at a grammar-school and afterwards became a student at the University New-
In 1792 Mr. Jones was appointed classical and mathematical teacher in the Welsh Academy, Swansea, which situation he held about three years, and then settled at Flymbury, near the University place, where he remained two years. He then became the pupil of the Unitarian congregation at Halifax in Yorkshire. In about three years he removed to London, where he resided during the first five years of his life, chief of his committee, and teaching, and preaching occasionally in the place of others: he never took charge of a congregation. Soon after he came to London he married the daughter of Dr. Abraham Hume, of the Free Church in the Strand, but issue out of that again, and had two children. He died January 10, 1827, in Great Coram Street, London, and was interred in the burying-ground of St. George's Bloomsbury. A few years before his death he received the diploma of LL.D. from the University of Aberdeen, and was soon afterwards elected a member of the Royal Society of Literature.

Dr. Jones was the author of several works, some of which are religious, chiefly in support or defence of the evidences of Christianity. Of these one of the most important was, 'Illustrations of the Four Gospels, founded on circumstances peculiar to our Lord and the Evangelists.' London, 1806, 8vo. In 1803 he published a short Latin Grammar for the use of schools; in 1804, a Greek Grammar, which has been frequently reprinted, but the year before his death he removed and changed the title of 'Elements of Greek Grammar.' In 1812 he published a Latin and English Vocabulary, which he republished in 1825 as 'Anthologies Latinae, or a Development of the Analogies by which the Poets of Greece have been Covered from each other.'

The success of Dr. Jones' Lexicon was great, and a large impression was soon disposed of. The work, as might be expected, was not without its faults, and was roughly treated by the learned. The name of the author was, however, a guarantee to the communicative and the initiatory.

Dr. Jones' chief work, to which he devoted a great many years of his life, was his 'Greek and English Lexicon,' which was published in 1826, in one volume, 8vo, and again in 1826. Dr. Jones was one of the first to introduce into this country the practice of teaching Greek through the medium of English instead of Latin; and the first Greek and English Lexicon for general use was Dr. Jones'.' He afterwards abbreviared the medium for schools, 'The Tyro's Greek and English Lexicon.'

There have been several Greek and English Lexicons, not only in England, but in America. Soon after Dr. Jones' came out, Schrevelius' Lexicon was translated into English, and published by Valpy, a new edition of which came out in 1831. In 1826 Dr. Donnagan's Greek Lexicon appeared, and since that of Groves, Ewing, Dunbar and Barker; Hill's small School Lexicon, and lastly the Lexicon of Liddell and Scott, which is in one volume, 4to, in small type, with many thousands of references, and has already (1845) reached a second Edition. It is based on the German work of Littell.

The success of Dr. Jones' Lexicon was great, and a large impression was soon disposed of. The work, as might be expected, was not without its faults, and was roughly treated by the learned. The name of the author was, however, a guarantee to the communicative and the initiatory.

Josquin, Desprez—the name which it appears to us, after having collated various authorities, is the true one of this celebrated composer of the most ancient school of par-music—was, there seems little reason to doubt, a native of the Low Countries, though the honour of his birth is indirectly claimed by many Italian writers, while its date still remains a matter of inference; M. Fayolle thinks that the year 1450 may be assumed as the period at which he was born, and we are not inclined to differ from this opinion.

Josquin was a disciple of John Ockenheim, 'the eldest composer in parts on the continent,' says Dr. Burney, 'to whose works I have been able to find any remains,' and much of whose reputation arises from his having been the instructor of the songs by which it is known; the master and scholar were relatively to each other as Blow and Purcell. On the monument of the former, in Westminster Abbey, it is recorded that he was 'master to the famous Mr. Purcell.' It is probable that Josquin went into Italy with another of the same name, and there improved himself in the knowledge of his art; and this may have led to his having been thought a native of that country, a supposition to which the frequent addition to his name of Italian, or the word "del," may be attributed. It is certain that he was a singer in the pontifical chapel in the time of Sixtus IV., who sat in the papal chair from 1471 to 1484, for Adami speaks of him, in that capacity, in high honour, as well as of his conduct, calling him 'uomo sparse, per 'l invenzione.' Quitting Italy, he was, according to Grassepain, appointed Maître de Chapelle to Louis XIV., for whom he composed much music (containing, whose many amusing stories are told), and a motet or two or three was contrived for the dedication at the King's performance. Louis had made him a promise of a benefice; but neglected to redeem it. To remind the king the composer produced a motet beginning 'Memor esto verbi tu,' &c. This was not written by a less gifted than Josquin, for, on the words, 'Foroio me non est in terris viventibus;' Louis then took the hint, bestowed a benefice, and the composer expressed his gratitude in a third motet, commencing, 'Bonitatis maxime dedicato.' But the motet's remarks that desire proved more inspiring than gratitude, for the two first works very much surprised the past. The time of Josquin's decease is not known. He was buried in the church of St. Gudule, at Brussels, where his effigy and epitaph are, we believe, still to be seen. He was a very voluminous composer, and many of his works remain to attest his learning and genius. Hawkins gives a synopsis of them; Burney names more than one example; and several are to be found in the British Museum. 'He may,' says Dr. Burney, 'be justly called the father of modern harmony, and the inventor almost even of counterpoint.'

JOUVENET, jean, a celebrated French painter during the reign of Louis XIV., was born about 1644. He was first instructed by his father Laurent Jouvenet, but completed his studies in Paris, where he soon attracted the notice of Lebrun, who in 1673 procured him his election into the Academy of Painting, for a picture Father before Abbeau, which is one of the best paintings of the Academy collection. Jouvenet had obtained considerable distinction two years previously by his picture of the Lasso Man painted for the so-called Duc de Seville, or Le tableau du Mal of 1675. The May Picture is a painting which was formerly presented on the 1st of May of every year to the Virgin, in the cathedral of Notre Dame, by the Goldsmiths of Paris; the practice ceased in 1709. Jouvenet became successively professor, director, and perpetual rector of the Academy, and he was granted a small pension by Louis XIV. He died in 1717.

The French bust of Jouvenet, as of Le Sueur, because he never visited Italy; and it is for the same reason, according to some, that he is censured by Count Algarotti, who, they say, had no faith in an excellence that could be acquired out of Italy. The style of Jouvenet is perhaps more of respect or even attractive, yet they possess all the greater merits of a picture in more than an ordinary degree. His style resembles that of Nicolas Poussin, especially in composition. The works of Jouvenet are chiefly in light and shade, but in expression he was never great.

Jouvenet's last work, the Visitation of the Virgin, or Le Magnifique, in the cathedral of Notre Dame, was painted with his left hand in 1717. He had a paralytic stroke in 1713 and lost the use of his right hand, but upon the first trial he found his left as good as if the right had been; one of the many proofs that, in art, it is not the hand but the mind that requires the education.

There are ten of Jouvenet's pictures in the Louvre, some of which are his best works, as the Miraculous Draught of Fishes, the Resurrection of Lazarus, the Sellen driven from the Temple, Christ in the House of Simon the Pharisee, and the Descent from the Cross. The first four have been worked in tapestry of the Gobelin, and they have all been engraved, as have also numerous Journeys best works, by some of the best French engravers—by H. S. Thomasin, J. Audran, E. Picard, L. Desplaces, A. Loir, A. Trouvain, and others. There are works by Jouvenet in many of the churches of Paris, and many pieces. Of his mural paintings the principal are the colossal frescoes of the Apostles painted on the dome of the church Des Invalides.
sib: success, and was at an early age admitted a member of the Society of the Jesuits. He devoted himself chiefly to history, and is the author of the 6th part of the history of the Jesuits from 1591 to 1616, which was published at Rome in 1710. Though an agreeable writer, from the purity and elegance of his style, his facts are not to be impudently relied on. So he has only produced the 3rd part of the history of the Jesuits, an apology of the Jesuit Guignard, who was executed in the reign of Henry IV. of France, on account of his participation in the attempt made against the life of that monarch by Jean Clouet. He was convicted of the crime by the evidences and censured writings of Guignard. An abridgment of his history was published at Liege in 1716, which is now rarely to be met with. The other works of Jouvenel are—1, A Collection of Cases, in the Courts of Law and Equity, consisting of 3 volumes, published at Paris. 2, A Collection of Cases in the Courts of Law and Equity, consisting of 2 volumes, published at Brussels, 1709, 1710. These include some cases, but contain too superficial an abridgment of mythology. 3, A Collection of Notes on Horace, Persius, Juvenal, Martial, and the 'Metamorphoses' of Ovid, which is considered his most valuable production. He died at Rome in 1718, while engaged in the continuation of the History of the Jesuits. His name is mentioned in the art. Jansenists, P. C., among the distinguished members of that Society.

JUDGE (from the French juge, which is from the Latin iudex). [Dixc: P. C.] A judge in England and Wales is a man who presides in a court duly constituted, declares the law, explains ambiguous terms of an act, interprets precedents, pronounces sentence or judgment according to law. There are judges of the three Superior Courts of Law at Westminster, judges in the Courts of Equity, a judge in the Court of Bankruptcy, judges of the Insolvency Court, judges in the Ecclesiastical and Admiralty Courts, and some others. Some judges are called Recorder, and there are other names, but the name does not alter the nature of the office. When the judges simply are spoken of, the judges of the superior courts of common law are meant. There are fifteen judges of these courts: five in the Court of Queen's Bench, five in the Court of Common Pleas, and five in the Court of Exchequer. There are at present five judges in Equity. [Courts, P. C.; Equity, P. C.]

The judges of the superior courts of law are appointed by the crown. They hold their office during good behaviour, but they can be removed by the crown on the address of both houses of parliament (13 Wm. III. c. 2). Formerly their commissions ceased upon the demise of the crown, but by the 1 Geo. III. c. 23, they continue to hold their offices during good behaviour notwithstanding any demise of the crown, and their salaries are paid. They are also paid allowances out of the office. The judges of the courts of Equity are also appointed by the crown. [Chancellor, P. C.; Chancellor, P. C.]

By various acts of Parliament retiring pensions of a determinate sum are given on retirement of the judges of the three superior courts of law, and to the judges in Equity. The lowest retiring pension is 3500L, and this amount may be given to all saline judges of the three courts. The highest retiring pension of 10000L is given to the judge of the Exchequer, the lord chancellor, or the chief justice of the common pleas, on his demise, and is paid by the crown to the lord chancellor upon his resignation. But to be entitled to these pensions all the judges of the superior courts of law, and the judges in Equity, except the lord chancellor, must have held the office for fifteen years, unless bad health has prevented them from holding office so long. Judges of Courts of Record [Courts, P. C.] are not liable to prosecution for anything done by them as judges, but they may be prosecuted in parliament. Nor are they liable to action for any error in judgment or for wrongful imprisonment, at least when they are acting within their jurisdiction. Judges are punishable for bribery, by loss of office, fine, and imprisonment.

The powers and duties of judges would form the subject of an elaborate treatise. It may be sufficient to observe that in England the judges of the superior courts are so well protected in the discharge of their trusts as to make them entirely independent of all political and private influence, and they are paid well enough to secure them against all temptation of lucre. Accordingly an instance of negligence, error, or crime, is generally found in a judge who holds a high office, is now seldom or never heard of. The only question that can be raised is, whether the most competent persons are always appointed, and whether persons who are not all or any one wholly and lately incompetent, are much less competent than others, and sometimes hardly competent. The danger is somewhat limited by public opinion, and particularly by the opinion of the members of the House of Commons. It is that the incompetent persons being appointed is not great. But as the appointment of the judges in the superior courts of law, and the judges in Equity, is really made by those who for the purpose have a direct interest in the subject, there is a danger of favoritism. These appointments are made by the minister, and are so made that the appointments are made by the minister, and are of the minister. This evil, so far as it exists, is increased by the constitution, and is probably a much less evil than any other mode of appointment that could be suggested. The nature or form of the judgment varies according to the nature of the action, the plea, the issue, and the manner and result of the decision: 1st. If the issue be for the plaintiff. If it be an issue at law arising upon a dilatory plea, the judgment is, that the defendant or the court over him, is called a respondent. Upon all other issues in law, and generally in fact, the judgment is that the plaintiff do recover, which is called good recovery. 2nd. If the issue be against the defendant. The issue being on a dilatory plea, whether of law or fact, the judgment is, that the writ or declaration be quashed or the plea be bad. If the issue be upon a demurrer, or in the judgment is that the plaintiff take nothing, which is called a judgment nil capiat. When judgments are given by default, or confession without issue, if for the plaintiff, they are good subsequent, if for the defendant, nullum. Besides the question at issue being decided by the judgment, the costs of the suit are generally directed to be taxed
and paid by the party against whom the judgment is de-
delivery, to the party who is the plaintiff, when given of
the plaintiff, orders that the defendant 'be in mercy,' that is,
amended or fined for his delay of justice; and when for the
defendant, that the plaintiff 'be in mercy' for his false claim.
A writ called, a writ that is not liable to be taken in execution by a judgment creditor for debt or damages. The remedy was extended by the 13 Edw. I. stat. 1, c. 18 (West. 2), to the creditor over a mortgaged interest of the debtor, for which a bond called a writ called an elegit was created, including all freehold estates and interests which the debtor held in securi-
ity, or in common, and all rent charges; but copyholds were held not to be liable to be taken in execution under this writ. By a fiction of the law, judgments were considered to take effect from the first day of the term in which they were signed, and therefore a purchaser might have his estate en-
cumbered by a judgment acknowledged subsequently to the purchase. To remedy this injustice it was enacted by the Statute of Frauds (29 Car. II. c. 3), that any judge who should sign judgments, should at the time of signing set down the names of the defendant, and that such judgments should operate from the date appearing on the margin. As, however, this did not compel the plaintiff to bring in the writ of elegit, which was only a writ of elegit before the court would listen to any application to re-
move the legal impediment. Upon the same principle that it assisted the creditor who had no relief at law, the court of equity did not permit a judgment against a trustee, though a law be given in the year to affect the beneficial interest of the usufructue.

As under the last mentioned clause of the Statute of Frauds a judgment did not affect the landlord in the hands of the trustee, until the writ was absolutely deposited in the hands of the sheriff, a purchaser of the equitable estate without notice might by getting in the legal estate protect himself against prior judgments; but if the purchaser bought with notice of the judgment, no acquisition of the legal estate would protect him. Rights of redemption were decided to be not such trust estates as to be included by the Statute of Frauds, the debtor not having the sole beneficial interest.

In the case of lands contracted to be sold, the purchaser is relieved in equity against judgments entered up subsequently to the contract; and also where land is conveyed to trustees for sale, whose receipts are to be sufficient discharge, the pur-
caller will not be bound by any subsequent judgments of which he has even express notice.

But when passing the acts of 1 & 2 Vt. c. 110, 2 & 3 Vt. c. 111, 3 & 4 Vt. c. 89, the law of judgments remained in the main unchanged. By these decrees and orders of Courts of Equity and rules of Courts of Common Law, and orders of the Lord Chancellor in matters of bank-
ruptcy and lunacy, were given the security of the creditor has been extended from a moiety to the whole of the debtor's lands, including copyholds, making leaseholders bound in the same manner as freeholders. And as all lands are included by the acts, over which the debtor may have a disposing power, judgments against a tenant in tail are binding on his issue; for the tenant might at any time have aquired the entail. So also were equitable of redemption and trust estates, in which the debtor had only a partial interest. After passing this act a question was raised whether stock was comprised, in which the debtor had only a partial interest, but the stock was to be regarded as taken in by a clause of the writ of elegit, if the goods and chattels of the debtor were to be taken in execution, or the writ of elegit to his real estate, thereby changing that which was before a naked right into an equitable interest, limited nonetheless to the amount of the debt or damage for which judgment was originally en-
termed.

A judgment at the time of entering up became a general lien upon all property, real and personal, which the debtor then held or subsequently acquired, and gave to the creditor a legal right, so long as the judgment remained on the records of the court and unstayed, to enter upon and reduce into possession of the property, by bringing out the writ of elegit, if the goods and chattels of the debtor were to be taken in execution, or the writ of elegit to his real estate, thereby changing that which was before a naked right into an equitable interest, limited nonetheless to the amount of the debt or damage for which judgment was originally en-
termed.

As to personal estate, it was enacted by the 16th section of the Statute of Frauds, that the goods and chattels of the debtor shall be bound by a judgment only from the time of taking out execution. And on the interpretation of this clause it was held that chattel interests in lands were included under the term 'goods and chattels,' and were still liable in the case of a fraudulent assignment after entering up judg-
ment and before execution, a court of equity would assist the
of any estate whatsoever, at law or in equity, or over which he may have any disposing power. All judgments are made binding on the persons against whom they are entered up, and against their assigns. The judgment creditor being entitled to the same remedies in a court of equity as if the debtor had by writing agreed to charge the lands, &c. The creditor is not however to proceed in equity to enforce whatever judgment he may have obtained against a principal creditor, until one year from the time of entering up such judgment; and in case of bankruptcy, the judgment, unless entered up one year, is to give no preference to the judgment creditor beyond creditors, the joint owners, or the confiscation of the debts of the bankrupt, with such other security as may be required. The extent of such additional security is to be fixed at the rate of four per cent. on the judgment debt, as well as to the debt itself.

Old dockets which existed since the 4 & 5 W. & M. are now finally closed, and no judgment, decree, or order, by virtue of the 1 & 2 Vict. c. 110, can affect purchasers, mortgagees, or creditors, unless and until a memorandum or minute of the judgment, &c., with the person's name against whom and the date when it was recovered, is left with the senior master of the Common Pleas at Westminster, who is to enter the same in a book kept for the purpose, in an alphabetical order by the name of the persons whose estate is to be affected.

In order to keep alive old docketed judgments, it was made necessary to register them according to this provision before a certain time fixed by the act, or they would be deemed satisfied.

Under the old law a purchaser was bound by undocked judgments of which he had notice, and it would seem that an undocked judgment is now entitled to the same consideration as an undocked judgment was, it being expressly provided by the late acts that the judgment creditor shall not take advantage of the extended remedies unless the judgment be duly registered according to their provisions. [Nottc., 1 & 2 Vict. c. 110].

The transfer of property is also greatly reduced, for the 2 & 3 Vict. c. 11 requires all judgments to be re-registered every five years from the date of the last registry, otherwise they shall be treated like mortgages, and be chargeable as such upon the lands, and creditors. But here again it may be presumed a purchaser with notice of a registered judgment more than five years old will be bound by all the remedies to which recourse might have been had by the judgment creditor previous to the passing of the late statutes. The provisions for registration, it must however be remembered, refer to the remedies which the judgment creditor may have against purchasers for valuable consideration with notice; but as between the creditor and the debtor, or his representatives or volunteers, the judgment remains in full effect until twenty years from the time of entering up or last register, or in general of judgment creditors among themselves before the late acts depended on the time when they respectively sued out execution; but in a suit for the general administration of assets the judgment creditors took priority according to time of the entering up their judgments. Now as they are entitled to such remedies in equity as if the debtor had by writing charged his land, they take priority in respect of their judgments from the times of registration. It has been questioned whether a subsequent judgment creditor without notice having used out his writ of execution is not entitled to priority over an equitable mortgagee, but the point has been decided in favour of the latter, upon the ground that it must be presumed the judgment creditor had no notice of the title, and therefore liable to all prior equities. (Whitworth v. Gaugain, 3 Hare, 461.) By these statutes judgments of the courts of the counties Palatine of Lancaster and of Durham, machinists and other judgment creditors are given in the courts of Westminster. But no judgment of those courts is to affect lands in the hands of purchasers, mortgagees, or creditors, unless a memorandum of such judgment for that purpose be filed in the county court by the person who is to register the same, in a book kept for the purpose.

Judgments or orders of inferior courts of record, in which a barrister of not less than seven years' standing shall preside, may receive the same effect for the purpose of removing a debtor from a court by a judge's order to remove them into a superior court. But until execution be actually issued, they will not affect lands in the hands of purchasers, mortgagees, or creditors, except as far as they would affect them as judgments of an inferior court.

In criminal proceedings, after trial the defendant can move in arrest of judgment at any time before judgment is pronounced, but this can only be done upon error appearing on the face of the record, and no motion of this sort can be made in the defendant's absence unless a verdict is found in which the jury reserve a point for the consideration of the court. After the judgment is recorded, a writ of error is necessary before it can either be reversed or altered. Formerly no judgment affecting the liberty of the individual could be deemed pronounced in his absence, but this has been altered by the 11 Geo. IV. & 1 Wm. IV. c. 70, which authorizes the filing of informations upon trials for felonies or misdemeanours; judgment may be pronounced whether the person affected be present or absent, and in that case the judgment is recorded.

The judgment of the court extends to the life and liberty of the offender according to punishment decreed to the offence against which the judgment is delivered. In some cases it extends to the compensation for forfeitures of lands or goods, or both, of the offender; others induce a disability of holding offices or fix a lasting stigma on the offender; and a large proportion are merely pecuniary by stated or discretionary fines.

On the subject of judgments see Chitty's General Practice; Stephens, On Principles of Proceeding in Civil Actions; Sudgen's Vendors and Purchasers; Frideaux, On the Law of Judgments as they affect Real Property.

JUGGARNAUTH, TEMPLE OF, in Hindustan, is situated in the province of Orissa and district of Cuttack, in 19° 47' N. lat., 85° 55' E. long., about 45 miles south from the city of Cuttack, and 811 south-west from Calcutta, direct distances. The temple, which is named after the Hindu god Jagannath, is 350 feet high, and is placed within it, stands on the coast of the bay of Bengal, and is a huge architectural mass, a sort of pyramidal tower, 200 feet high, built of coarse red grout, and covered with a rough coating of yellow clay. The temple is divided into three stories, and encloses an angle of space within a high stone-wall, each side of which is 650 feet long. It is a very conspicuous land-mark, and is of considerable importance to navigators on the east and uniform coast where it is situated. The country, to the distance of about a mile from the sea, is a waste of deep lood sand; farther inland it consists of low sand-hills covered by a thick forest of dwarf trees. The quadrangular enclosure is at the end of the principal street of the sea port town of Pooroo, or Jagannathpoor, a place of considerable size, but ill-built and dirty. The temple has no claim to very high antiquity, and 1n the year 1676 or 1677 the temple was destroyed by the English for purposes of trade.
It is customary for numbers of congregated persons to throw themselves under the wheels, and even fathers and mothers with their children in their arms. The chariot passes on, as if it had been deserted, and evidently unprepared to convey them immediately to heaven. On this passage Professor H. H. Wilson, in his new edition of Miller's work, has the following note (vol. i. p. 416):—"It is not likely that so many people throw themselves under the chariot wheels. Mr. Stirling, who was resident in Orissa for four years, mentions, that during that period there were no more than such instances. The cause of the accident was not known, whilst the other two were cases of painful and incurable disease. But this practice is modern: Jagnannath himself is modern, and has no place in the Visnudva Paranam. It is not infrequent that those who have reached repose are struck whilst a place of pilgrimage no longer ago than a century" (that is, in 1740).

(Hamilton, East India Gazetteer: Emma Roberts, Scenes and Characters of Hindustan; Rennell, Maps of a Map of Hindustan; Mill, History of British India, by Wilson: Wilson, Sanskrit Dictionary.)

JULIANUS, SALVIUS, was probably a native of Milan. He was the great-grandfather of the Emperor Didius Julianus. (Aelianus Spartanus, Deditus Julianus.) Julianus was twice consul, and also Prefectus Urbis. He mentions his own consalship and office of Prefect Urbis and he also speaks of the manner he conducted all his laws and writings. Julianus was a distinguished jurisconsult, and one of the Consistiat of Hadrian; and he may probably have obtained the honour of the consalship under this emperor. Lactantius (c. 3) speaks of the Doctor Jurisconsultus Julianus for the Doctor jurisconsult Julianus, who was professor and authority on the jurisconsult, and he speaks of the jurisconsult Julianus, who was professor and authority on the jurisconsult, and he speaks of the jurisconsult Julianus, who was himself killed in the reign of Antoninus Placcus. The seculum of the jurisconsult was on the Via Lavicana, five miles from Rome, according to Sp Artius, and his descendant the Emperor Didius Julianus was buried in the same tomb. (Didius Julianus, c. 8.)

Salvius Julianus was a pupil of Joveneus Priscus, and therefore one of the Sahithiani. His authority was very great among the Roman jurists, and he is often cited by another writer by the Roman jurists, even more frequently than Labeo. The great work with which his name is connected was the Edictum Perpetuum, which was compiled in the time of Hadrian. [Educal Law, P. C. S.] His principal legal work was Ninety Books of Digests. There are 457 excerpts from Julianus in the Digest of Justinian, and chiefly from the work just mentioned. There are also mentioned, in the Florentine Index, Six Books Ad Minorum, Four of Fishianum, and One Book On Amilquities (De Ambiguities).

JURIEU, PIERRE, was born in 1857, and was the son of a Protestant minister at Mess, in the diocese of Blois, and nephew of Charles, Bishop of Rives and Bishop of the department of Indre, who, on the approach of age to enter the ministry, succeeded his father in his pastoral office. His reputation for leaning afterwards obtained for him the situation of Professor of Theology and the Hebrew Language at the University of Westminister. When his colleagues were deprived of the permission to give public instruction in that town, he retired to Rouen, and from thence went to Rotterdam, where he was appointed Professor of Theology. In that city the ardour of his zeal soon drew him into controversy with Bayle, Basnage, and Saurin; in the heat of which he manifested the same rancour which unfortunately disguises most of his polemical writings. He allowed himself likewise to fall into various errors by too much indulging a natural and lively imagination in the interpretation of prophecy. In his Commentary on the Apocalypse he even predicted the establishment of Protestantism in France during the year 1686. These errors, which he derived from his infidelity, were not surprising. When the great character for learning and piety, he treated with a most unbecoming severity. Grous and Hammond, perhaps the two greatest theologians of their age, because they differed from him in their opinions, however high their character for learning and piety, were treated with a most unbecoming severity. Grous and Hammond, perhaps the two greatest theologians of their age, because they differed from him in their opinions, however high their character for learning and piety, were treated with a most unbecoming severity. Grous and Hammond, perhaps the two great...
guardians of the realm, during his absence; and similar appointments were very frequent under the early Norman and Plantagenet kings. When a king was in need of a great revenue, as was the case of King John, in his reign, he sold it to the highest bidder. One by Edward I. to the Earl of Pembroke describes the powers of the office in terms which imply that it had long been familiar, as extending over all the things which the crown could do (dictum in dicta custodia pertinet); and the same words are common in subsequent commissions. And down to the present time similar officers have been appointed under various names, and with various jurisdictions. The regent, Protector, lieutenant, or locum tenens, and regent, have been among the other names by which they have been known. Regents and councils of regency, during the monsoon of the king for a time, with the crown, are sometimes possessed of the crown; but in modern times such arrangements have been usually made by statute. Coke remarks (4 Inst. 68), that the methods of appointing a guardian or regent have been so various, that 'the surest way is to have him made by authority of the great council in parliament.'

The most familiar case of the appointment by the crown of a representative executive power, not in a colony or dependency, is that of the appointment of a governor for Ireland, who has commonly borne the name of the Lord Lieutenant or the Lord Deputy; or of a council of government, known as the council of the realm.

The governor-general of Ireland under the crown has been styled at different times custos (keeper or guardian), justiciary, warden, procurator, seneschal, constable, justice, deputy, and lieutenant. The last of these names has been most during the last 200 years. Formerly, upon the avoidance of the king's lieutenant for Ireland by death or otherwise, the privy council there was authorized to elect a successor, with the restriction that he should be an Englishman and no spiritual person, who hold office till the king appointed another. The antient powers of this officer were almost regal; he performed every act of government without any previous communication with England, and which he thought was not to the interest of the crown. From about the time of the Revolution, however, till after the commencement of the reign of George III., the lord-lieutenant resided very little in Ireland; in several instances the person who was appointed was never over. In other cases he went over once in two years to hold the session of parliament; and the government was very often left in the hands of lords justices, without a lord-lieutenant at all. In modern times the appointment of lords justices for Ireland has been taken place on the occasional absences of the lord-lieutenant, and during the interval which has sometimes occurred between the demise of one lord-lieutenant and the appointment of another. That which has been thus tolerated is the result, not of any conduct of the lords justices, but of their duty to the crown, the chancellor, and the commander of the forces.

In England lords justices and regencies have been repeatedly appointed since the Revolution, on occasion of the king going abroad. When the crown was left vacant by his having been made by royal letters patent under the great seal, in the same manner as the lords-lieutenant or lords justices of Ireland have always been appointed. In some cases, however, the queen has appointed the person without the royal warrant, as in the case of Mary. When King William went over to Ireland, in 1688, he of his own authority appointed the administration of the government to be in the hands of the queen during his absence out of the kingdom, not; however, we suppose, by letters patent, but merely by declaration at the council-table; and at the same time an act of parliament was passed, 1 & 2 Wm. and Mary, sess. 2, in the preamble of which that declaration of his majesty's pleasure was recited, and it was enacted, that whensoever and as often as his majesty should be absent out of this realm of England, it should and might be lawful for the queen to appoint and administer the regal power and government in the names of both their majesties, for such time only, during their joint lives, as his majesty should be absent. This act was considered to be necessary or expedient, in consequence of the regent having always in which the queen was placed by the Act of Settlement, which had declared that the entire, perfect, and full exercise of the regal power and government should be only in and executed by his majesty in the council of regency, or in the council in which the queen was annexed, shall be in his majesty only, as if this act had never been made. After the queen's death lords justices were repeatedly appointed by King William, on occasion of the possession of the crown shall go out of the dominions of England, Scotland, or Ireland, without consent of parliament.' This clause, however, was repealed in 1716, by 1 Geo. I. stat. 2, c. 51. The words 'without the consent of his majesty' are altered to the words 'whose impudence to visit his German dominions,' says Coke in his Life of Walpole, i. 77, 'now became so great as totally to overcome every restraint of prudence and suggestion of propriety, and he absconded to the mere insinuation of the ministry,' continues the historian, 'were considerably embarrassed on this occasion; and drew up a strong remonstrance, representing the inconvenience which would result from the projected journey. The remonstrance, however, not only failed of success, but so far exasperated the king, that he declared he would not endure a longer confinement in this kingdom.' It was thought more respectful to his majesty to obtain a repeal of the restricting clause at once, than to ask parliament merely for the leave of absence; and the bill passed through all its stages in both Houses without a dissentient voice, the Tories, Sir Robert Walpole, and the Whigs, being all in favour of the measure. King George II. was so animated by the same spirit, and his Majesty, who was at variance with his oldest son, now interposed another difficulty, refusing to intrust the government to the crown prince, and to admit persons with him in the commission, and also limiting his authority by the most rigorous restrictions. Upon this point, however, he yielded at last to the representations of the ministers, who concluded a long expedition of reasons against his leaving the kingdom at all at that crisis by stating, 'upon a careful perusal of the precedents, finding no instance of persons being joined in commission with the Prince of Wales in the appointment of a regency, &c. and few, if any, restrictions upon such commissions,' they were of opinion that the constant tenor of antient practice could not conveniently be receded from. (See the paper in Coke, ii. 51-64.) Upon this the king submitted to give the prerogative to the execution of affairs; 'yet,' says Coke, quoting from the work called 'The Political State of Great Britain,' 'he appointed him Guardian of the Realm and Lieutenant, an office unknown in England since it was enjoyed by Edward the Black Prince.' In point of fact the title given to the prince in the original Latin commission was Custos Regni nostri et Locum tenens, which were the same words that had been commonly used in all such commissions down to the reign of Henry VIII., with this difference only, that one of the two titles (more frequently Custos Regni) was alone employed. The earliest use of the term regent appears to have been in the commission from Henry VIII. to the Protector Somerset, in 1544, and it is styled Rectrix et Gubernatrix Regni nostri. Queen Mary, the wife of William III., whose case is the next that occurs, seems, as already stated, to have had no commission of office; and perhaps, if the crown in her own right, she was not even popularly styled regent.

When George I. went abroad the next time, in May, 1710, he intrusted the government during his absence not to a regent, or any single person, but to thirteen lords justices, namely, the Archbishop of Canterbury and the principal officers of the state. A translation of the commission issued on this occasion, or rather, of the warrant to the attorney-general to prepare the commission, has been printed in the report of a committee of the House of Commons which sat in December, 1788, and affords us probably the most complete information to be found, in a printed form, on the subject of the present article. The committee state that they had four or of any earlier commission, except of the one issued in 1695, and that that was nearly the same with this of 1719, which appears to have been also the basis of a subsequent one, issued in 1729. The commission begins by reciting that his majesty had determined, for divers weighty reasons, speedily to go in person beyond the seas.' The persons commissioned are appointed to the several offices. 'His majesty, as is annually done by (Justiciar) must be the Latin term) of our said kingdom of Great Britain, and our lieutenants in the same, during our absence out of our said kingdom, till further designation in that behalf from your highness, the authority given to the justiciar, and his deputy's, to perform the functions of a justiciar, to execute the office and place of guardians, &c., and to order, do, and perform all and every act and acts of
government and administration of government, and all other matters and things whatsoever, which, by virtue or by reason of the nature of their place, have been lawfully ordered, done, or performed. Power is afterwards specially given to keep the king's peace, to cause the laws and customs of the kingdom to be specially observed by all, to create and appoint persons to the parliament there the power to exist, and to continue, prorogue, and dissolve it, and likewise to summon and hold another parliament and other parliaments, and the same to continue, prorogue, and dissolve; also to direct such authority to the lieutenant, or justices and general governors, of the kingdom of Ireland for the time being, to summon, hold, prorogue, and dissolve the parliament and parliaments in the said kingdom, and likewise to prepare and transmit the bills which may be proposed to be enacted in such parliaments, according to the laws and statutes of the kingdom of Ireland; to summon and hold the Privy Council, and to appoint committees of the same; with the advice of the Privy Council, to issue proclamations, 'and to do and perform all other things which have been usually done, or may be done, by us, by or with the advice of the same; to appoint and authorize persons to treat with the ambassadors, consuls, and ministers of kings, princes, republics, or states, and to make and conclude treaties, conventions, and leagues thereupon; to confer, grant, and present, to all his subjects, dignity, and ecclesiastical promotions, whether ancient or in the creation; to appoint and remove his officers, appoint, and ordain, and to discharge officers, to the proper service of the kingdom; to appoint and to ordain, and to discharge from all offices at the disposal of the crown; to grant pardons for high treason and all other crimes and offences; and finally, to do all those things in Ireland as well as in Great Britain.

This enumeration is probably the most authentic compendium that has been published of the powers of government ordinarily exercised by the crown. It does not, however, profess to be an enumeration of all the powers resident in the crown; and it will be especially observed, that (besides, perhaps, some appertaining to the office of supreme head of the church) the power of creating peers and conferring honours is not made over to the lords justices. That is a power which, we believe, never has been delegated, or attempted to be delegated, if we except only the case of the grant by Charles I., in 1644, to Lord Herbert (better known as the Earl of Pembroke) of the office of the king's private secretary, which, after his flight, was compelled to resign by the interference of the House of Lords.

In the Lords justices, there is a further restriction in the commission of 1719, in the execution of their powers, punctually to observe his majesty's will and pleasure, as it might be from time to time more clearly and distinctly expressed in instructions signed by the royal hand; and the commission was accompanied by a set of instructions, also printed in the Report of the Committee of 1778, and stated to be nearly the same that had been issued, as far as was known, on similar occasions before and since. The rules prescribed are twenty-one in number, the most important things directed in which are, that no livings or benefices in the gift of the crown which may become vacant shall be disposed of without his majesty's directions as to the persons, to be signified from beyond the seas under the sign manual; that no orders or directions concerning the disposition of money at the treasury shall be given before his majesty's pleasure shall have been signified thereupon; and that there must be no exercise of the power of dissolving the parliament, or calling a new one, without special signification of the royal pleasure. The same restriction is put upon the exercise of the power of pardoning, and some other executive powers. In case however they should hold it necessary to issue proclamations for the public safety, the Lords justices are authorized to fill offices immediately, and also to suppress crimes; and they are permitted to continue the sitting of parliament by short proroguations, until they should be otherwise directed under the sign manual, and to summon the privy council to meet as often as they shall see occasion.

The government was in the same manner intrusted by George I. to Lords Justices when he again went abroad in 1720, 1725, 1726, and 1727. It is strange that the Report of 1788 should notice only the second of the several regencies of Queen Caroline, in the reign of George II. Her majesty so long as she lived was always intrusted with the administration of the government when the king went abroad; which he did in 1729, in 1732, in 1736, 1739, 1742, 1746, 1749, 1752, and 1755. 'To enable her majesty to be regent of this kingdom, during his majesty's absence, without taking the oaths,' on the 15th of May thereafter, according to Salmon's 'Chronological Historian,' the council passed the great seal constituting her guardian and lieutenant of the kingdom during the king's absence; and the same authority states her to have been appointed guardian in 1732, and regent on the two other occasions. On the 10th of April, by the 2nd anne, 1st and 2nd anne, 1752, and 1755. On all these occasions the commissions and the accompanying instructions were nearly the same with those issued in 1719.

George III., during his long reign never left England. When George IV. went to Hanover in September, 1821, nineteen guardians and Lords Justices were appointed, the Duke of York being the first. In an important article which forms the conclusion to the present part of this work, we have quoted from the writer, after stating that Lord Eldon considered it indispensably necessary that Lords Justices should be appointed upon that occasion, adds: One good effect arose from their appointment, that the king during his absence signed an immense number of military commissions and other documents, which had been accumulating since his accession to the throne. This writer contends that the king's regular appearances in the English parliament might be exercised in a foreign country. 'We take it,' he adds, 'to be quite clear, that a patent sealed with the great seal in a foreign country would be void. To guard against any such irregularity, the law requires that the patent shall state the place where it is signed and sealed as opud Westmonasteriam.'

Nevertheless, no provision existed for the absence of the sovereign on such occasions was made for the exercise of the executive authority, either when her present majesty made her short excursion to the French coast in 1844, or when she made her late more extended visit to Germany (in August and September, 1845). In 1848, upon the creation of the regency, the queen was appointed regent during the minority of her son, and the intention was that Lords Justices should be now appointed? the lord chancellor, however, replied that the government had no such intention. 'On the occasion of her majesty visiting the king of France,' his lordship is reported to have said, 'the then law officers of the crown, the present lord chief baron and the late Sir William Follett, had been consulted. . . . And after mature deliberation, these learned persons gave it as their decided opinion that it was not at all necessary in point of law that such an appointment should take place. . . . In the present instance also, the law officers of the crown had been consulted as to whether it was necessary in point of law for her majesty to appoint a regency during her absence, and their reply was that it was in no degree necessary; an opinion in which he entirely concurred.' Both the speech with which Lord Campbell prefaced his question, and the subsequent article in the 'Morning Chronicle,' will deserve to be consulted.

It ought to be mentioned that the seven persons appointed in 1706 by the 4 & 5 Anne, c. 6, and again in 1707, by the 2 & 3 Anne, c. 2, and in 1710, by the 4 & 5 Anne, c. 13, to assist the king, were other persons whom the new king or queen should have named, in case of his or her absence at the time from the kingdom, are styled Lords Justices in the act, although called regents in the act. Accordingly, these Lords Justices (twenty-six in all), who actually came into office on the death of Queen Anne, 1st August, 1714, and continued till the arrival of the king on the 8th of September, enjoyed more extensive powers than any others that have
been appointed, at least in modern times. They were authorized, in the name of the successor, and in his or her stead, to use, exercise, and execute all powers, authorities, matters, and acts of government, and administration of government, in as full and ample manner as such next successor could use or execute the same if she or he were present in person within this kingdom of Great Britain, until such successor should arrive, or otherwise determine their authority. The only restrictions laid upon them were, that they were not, without direction from the 'queen or king,' to dissolve the parliament; and that they would subject themselves to the pains of high treason if they gave the royal assent to any bill or bills for repealing or altering the Act of Uniformity, or the Act for the Establishment and Maintenance of the Presbyterian Church Government in Scotland.

We are not aware that these facts have ever before been put together. The most important of them have been derived from the Report of the Committee appointed by the House of Commons in 1788, 'to examine and report precedents of such proceedings as may have been had in the case of the personal exercise of the royal authority being prevented or interrupted by infancy, sickness, infirmity, or otherwise,' which is printed in the Journals of the House, vol. xliv. pp. 11-42. See also, besides the other sources that have been already referred to, an article 'On the Regency Question,' in the Edinburgh Review, No. XXXV. (for May, 1831), pp. 46-80. And some particulars may be gleaned from the accounts of the proceedings in the two Houses of Parliament on occasion of the king's illness in 1788, as reported in the 'Parliamentary History,' vol. xxvii. pp. 653-1297; and from the discussions on the Regency Bill from the beginning of November, 1810, to the middle of February, 1811, which nearly fill the 15th volume of the 'Parliamentary Debates.' One of the speeches which attracted most attention on the latter occasion for its argument and research was afterwards published in an authentic form; that delivered on the 8th of December, 1810, by John Lesch, Esq. (afterwards Vice-Chancellor).

JUSTICIARY COURT in Scotland. To render the historical article on this subject under the head of JUSTICIAI |

P. C. J fully intelligible, it may be mentioned that the High-Court of Justiciary is the supreme criminal court in Scotland. It consists of the Lord Justice General, Lord Justice-Clerk, and five other judges of the Court of Session. It sits at Edinburgh, from time to time during the year, according to the extent of business to be transacted. Offences committed in Edinburgh and within the district of the Lothians are tried before this court, and in cases where in other parts of the country waiting for the next Circuit Court would create too much delay, or where there is any other ground of expediency, the trial may proceed before the Central Court. Other trials in the provinces proceed before the circuit courts. These are held in spring and autumn, each by two judges deputed by the High Court of Justiciary. The southern circuit is held at Jedburgh, Ayr, and Dumfriess; the western, at Glasgow, Inverary, and Stirling; and the northern at Perths, Aberdeen, and Inverness. An additional circuit is held at Glasgow in winter. Questions may be certified from the circuit courts to the High Court of Justiciary, that is to say, before being decided the matter may be reserved for the consideration of that court. But it is a peculiarity both of the central and circuit courts of Justiciary, that no decision once given can be reconsidered either by the court pronouncing it or a Court of Review. This principle is liable to many objections, but it is productive of one benefit, that no trial is thrown away by the subsequent discovery of flaws in initial procedure. Before the case goes to a jury, a judgment is pronounced 'finding the indictment relevant,' and virtually declaring that the initial procedure is regular; that the charge is properly laid, and that the offence if proved is punishable. If there be any objections to the regularity of the proceedings, they must be stated before this judgment, which when once pronounced is final. All cases before the Court of Justiciary are tried by a jury of fifteen, a majority returning the verdict where they are not unanimous. It has jurisdiction in all the more serious offences except high treason, which is adjudicated in the English manner by a Court of Oyer and Terminer.

JUSTIFIABLE HOMICIDE. [MURDER, P. C.] JUVENTIUS CELSUS. [CELUS, P. C. S.]
KAFFA, a country in the eastern parts of Africa, of which we have only lately got some information, and which hitherto has been considered by any European traveller, so far unknown. It is said to be of considerable extent, larger than Shoa (Arsiminta, P. C. S.), and appears to occupy the space between 3° and 5° N. lat. and 30° and 34° E. long. It contains numerous high mountains, which are separated from one another by wide valleys. Numerous watercourses drain the country, and all of them join the Goshop, a large river originating in several branches to the south and west of Kaffa, which probably falls into one of the rivers whose embouchures have been recognised on the coast of Zanguebar. On the north of Kaffa is Enarea, and on the west a wilderness, in which numerous herds of large quadrupeds (elephants, giraffes, &c.) are found. The country is fertile, and partly well cultivated. Cotton is grown to a great extent. The coffee-tree is there, as well as in the neighbouring country of Enarea, indigenous and a forest-tree. It is not stated that coffee is an article of export, but it is thought that the coffee raised in these parts grows has derived its name from this country, as the Arabs assert that it has been transplanted to Yemen from that part of Africa.

The capital is Soocne, a town which, according to the accounts of African travellers, has between 6000 and 7000 inhabitants. This place and some others are visited by the merchants of Enarea, who exchange their goods (rock-salt, copper, and some Indian cotton) for Kaffa, brought from Gondar, for cotton, cotton-cloth, which is made in the country, and slaves; this is the only way by which the inhabitants dispose of their produce and obtain foreign goods. The inhabitants of it is in small numbers, are call themselves Christians, but none of the practices by which the Abyssinian church is distinguished are in use among them.

(Kraft, Bericht von dem Flusse Goshop und den Ländern Enarea, Kaffa und Dicho, in the Monatsschriften der Berliner Gesellschaft für Erdkunde.)

KAIN, LE. HENRI-LOUIS, a French actor, so often spoken of in the memoirs of French literature in the middle of the eighteenth century, that some account of him may be useful. He was born in 1728, and died in 1778. He was a protegé of Voltaire, who observed the natural strength of his histrionic genius, and removed him from an humble operative profession. He acquired his chief celebrity in the characters of Voltaire's plays; yet, owing to a singular series of events, that author never saw him on the stage. He was unable to make his début until fifteen months after Voltaire's departure for Prussia, in 1750, and on the author's return, after an absence from Paris of twenty-eight years, he found the actor about to be buried. Louis XV. stamped the reputation of Le Kain, by saying that "il m'a fait pleurer; mais qui ne pleure gagne." Like Étienne-Georges, whose figure bears a great resemblance, he was small in person, and his success arose from his power of representing deep passion and vehement emotion. The character of his acting was novel, and while it fascinated the audience, it did not at first satisfy the critics, who termed him le consolateur. He was critical and accurate in costume, and attended minutely to its topical and chronological applicability.

(Biographie Universelle.)

KALEIDOSCOPE, a name compounded of two Greek words (kalein and sopein), and denoting the exhibition of beautiful forms, is the designation of an optical instrument which was invented by Dr. (Sir David) Brewster, and made public in 1817.

About three years before that time Sir David Brewster, being engaged in making experiments on the polarization of light by reflexion from plates of glass, observed that when two plates were inclined to one another, and the eye of the spectator was nearly in the produced line of the common section of the planes of the two plates, the two extremities of the plates were multiplied by successive reflexions so as to exhibit the appearance of a circle divided into sectors, also that the several images of a condole near those extremities were circularly disposed about these rays in the same manner, which were suggested to him the construction of an instrument of the kind above named.

It may be observed, however, that the multiplication of the image of an object by successive reflexions from mirrors inclined to one another had long before been a subject of investigation in treatises on optics; and both Baptista Porta and Kircher had given descriptions of instruments consisting of mirrors united at two of their edges, which, being opened like two leaves of a book, were capable of multiplying the images of objects. Bradley also, about the year 1717, constructed an instrument consisting of a plane of glass inclined to one another, which being placed on a drawing, with the line of section perpendicular to the paper, exhibited to the eye several images of the figures, disposed by successive reflexions about a centre. But the optical investigations alluded to are very remotely connected with the properties of the kaleidoscope; and the application of the latter to objects which may be movable and situated at any distances from the observer, render Sir David Brewster's instrument very different from and far superior to the simple contrivances of Porta, Kircher, and Bradley.

The essential parts of the instrument consist of two plane mirrors of glass, having their posterior surfaces blackened in order to prevent any reflexion of light from thence; mirrors of polished metal would, however, be preferable: each mirror is from six to ten inches long, and of a trapezoidal form; the longer end about an inch and a half long, and the shorter end about three-quarters of an inch; and the two are placed in contact with one another at a long end of each, as to form a dihedral angle, the like ends being placed together: the subject to be viewed is disposed contingently to the larger ends, and the eye should be near the opposite extremity, but a little above the line of contact. The effects produced by the reflexions of the light may be understood from the following considerations:

Let A, B, C, in the first of the figures, be the two extremities of the mirrors on the side farthest from the eye of the observer, which is supposed to be near the opposite extremity of the line of section passing through C perpendicularly to the plane of the paper. These lines A C, B C, and the sectorial space between them (which in the figure is one-eighth part of a circle), will be visible by rays coming directly to the eye; and, at the same time, rays from the line A C falling on the mirror B C at an equal angle of incidence will, after reflexion, give rise to the image C B of the line. These, with the intermediate rays, produce the first reflected sectors B C a and A C a. Other rays from the sector A C B at the surface of the mirror A C will fall on the mirror B C; and, while a portion of them arrive at such angles of incidence as to be reflected to the eye and produce the perception of the sector a C B, another portion of them will be reflected back to the mirror A C at such angles of incidence as to be reflected to the eye and cause the perception of the sector a C B'. In a similar manner the rays first reflected from B C a will, by subsequent reflexions, give rise to the perceptions of the line B C a'.

Thus it is easy to perceive that an object, as M, on A C, with its immediately reflected image M', will give rise to the appearances of similar figures at m, m', m''; and an object, as P, on A C, with an immediately reflected image N, will give rise to the appearances of similar figures at n, n', n'' also an object, as P, between A C and B C, will appear by reflexion similarly situated in all the other sectors.
If the angle A CB be 2 of four right angles, in which as is any term in the series of even numbers 4, 8, 10, &c., the number of grid, of the object will be equal to A C B, while C Y, the appearance of the line in which the mirrors meet each other, will, as in the figure, bisect the angle which is opposite to A C B; also if m be any term in the series 9, 5, &c., the number of the sectors will be m, and each of them will be equal to A C B, while C Y will coincide with the line in which the two lowest sectors join one another. It may here be easily understood that if a sector be placed in the sector A C B which is plane perpendicular to the mirrors, have its bounding-lines similarly situated with respect to A C and B C, the reflected images will be similar and equal to the original object; and the whole will be of a symmetrical pattern; but if the values of m be odd or even; but if the bounding-lines are not similarly situated with respect to A C and B C, the reflected images will not, in the two lowest sectors, unite so as to correspond to the images in the other sectors, unless m be an even number.

The second figure represents a pattern produced by the object represented in the sector corresponding to A C B in the first figure.

In order that the whole pattern in the field of view might possess perfect symmetry about the centre C, it would be necessary that the eye should be exactly in the direction of the line in which the glass plates meet one another; but in such a situation the reflected images would not be visible: if the eye were far above the line of meeting, the visible field of view would be sensibly elliptical, and the brightness of the field would be considerably less; it follows, consequently, that the eye should be near the smaller ends of the mirrors, and very little above the line of their junction. Again, it may be readily understood that, in order to permit the reflected images of objects to be symmetrically disposed about the centre of the field of view, the objects should be exactly in a plane conjugate to the mirrors at the extremities which are farthest from the eye; for in the line in which the planes of glass meet each other, there are a number of objects contained in the central part of the field of view, placed in the common centre of the visible sectors, if the object were placed on that line of junction, and either between the eye and those extremities or beyond the latter, it is evident, the eye being above the line of meeting, that the apparent or projected place of the object would not coincide with that common centre, but in the former case would appear below, and in the latter above, that centre. The length of the mirrors should be such that the object in the sector A C B may be distinctly visible; the eye may, however, if necessary, be assisted by a concave or convex lens.

The first kaleidoscopes constructed by Sir David Brewster consisted simply of the two mirrors, which were fixed in a cylindrical tube; the objects were pieces of variously coloured glass attached to the farther ends of the mirrors and projecting on the sectorial space A C B; or the objects were two glass plates of very thin glass, placed between two mirrors and held by the hand or fixed in a cell at the end of the tube. In some cases these plates were moved across the field of view, and in other cases round the circumference of this tube. The pieces of coloured glass or other objects which were situated in the sector A C B were, by the different reflections, made to appear in all the other sectors; and thus the field of view presented the appearance of an entire object or pattern, all the parts of which were disposed with the most perfect symmetry. By moving the glass plates between which the objects were contained, the pattern was made to vary in form, and pleasing variations in the designs were produced by moving the instrument so that the light of the sky or of a lamp might fall on the objects in different directions. When the objects in the sector A C B are confined near its upper part, the instrument evidently form an annular pattern; and, on placing the two mirrors parallel to one another, the successive reflections of the objects produce one which is rectilinear.

Sir David Brewster subsequently found means to obtain multiplied images of such objects as flowers, trees, and even persons or things in motion: and thus the importance of the instrument was greatly increased. For this purpose he caused the mirrors to revolve about a horizontal axis, and thus a new series of images was contained in another from which, like the eye-tube of a telescope, it could be drawn at pleasure towards the eye: at the opposite end of the exterior tube was fixed a glass lens of convenient power, by which there were formed images of distant objects at the place of the sector A C B. These images thus became objects which, being multiplied by successive reflections from the mirrors, produced in the field of view symmetrical patterns of great beauty.

Some kaleidoscopes have been executed in such a manner that the two mirrors may be placed at any required angle with one another, by which means the images in the visible field of view may be varied as much as desired. This expedient is also of being constructed so that the multiplied image may be projected on a screen, and thus made visible at one time to many spectators. In order to obtain this end, the rays of light from a point source, as, for example, a lamp, fall upon the object in A C B at the farther extremities of the two mirrors; and at the edge of the instrument is placed a lens of such focal length that the rays in each of the emergent pencils may converge upon the screen, so as to produce on the latter a magnified image of the whole pattern. The tube containing the glass plates is frequently mounted on a stand having a ball-and-socket joint, on which it may be turned in any convenient direction; and the instrument being thus supported, the figures in its field may be easily sketched by a skilful artist, who by means of such an apparatus may be greatly assisted in describing beautiful patterns.

Sir David Brewster's account of his invention is contained in his 'Treatise on the Kaleidoscope' (Edinburgh, 1819): but Dr. Roget has shown ('Annals of Philosophy,' vol. xi.) that the proportions of the instrument may be greatly extended by employing, instead of two, three, and even four plane mirrors, united together at their edges so as to form a hollow prism, or a frustum of a pyramid, the reflecting surfaces being turned towards the instrument. Thus if there be three, of which AC B, Kaleidoscopes, the instruments constructed with three plane mirrors appear to produce the most pleasing effects; the mirrors may be disposed so that a section perpendicular to the mirror AC B shall be a triangular prism, a right-angled triangle, or a right-angled triangle having its two acute angles equal to 30° and 60°. The first disposition of the mirrors affords regular combinations of images in three different directions which cross each other at angles of 60° and 120°; and to instruments of this kind Dr. Roget gave the name of Triascope. With the second disposition the field is divided into square compartments having the hypotenuse of the triangle for their side, and these are called quadrilateral compartments. This disposition exhibits a field of view divided into hexagonal compartments; and hence the instrument is designated a Hexascope.

Sir David Brewster obtained a patent for the kaleidoscope, and several opticians of London and other places were duly authorized by him to execute and sell them: but the refinements of taste are too often disregarded in the purchase of works of art; and, apparently, the public did not adequately encourage the manufacture of the instruments of a superior kind; while, in violation of the patent, imitations of the kaleidoscope, rudely and inaccurately constructed, were sold for a trifle, by persons who tell the public that it is doubtful whether the distinguished philosopher to whom optical science is on many accounts so highly indebted derived any pecuniary advantage from his invention.

KALENDAR, REVOLUTIONARY. It has been pointed out that there is a mistake in the commencement of the French revolutionary years as given in Year, P. C. On examination we find that not only the article cited, but many other works give an account of this calendar which is more or less incorrect. The decree of the National Convention, which fixed the new mode of reckoning, were both vague and insufficient; but it is no wonder that many detailed accounts agree neither with each other nor with the truth. To learn what the truth was, we have recourse to a French work, in its sixth edition: 'Concordance des Calendriers Républicains et Gregoriens,' par L. Rondonneau, Paris (Gérin edition), 1830, 8vo. This work gives two days of each year, from an A.D. II. to An XXII. both inclusive, opposite to its day of the Gregorian calendar: it also gives the decrees of the National Convention.

By these decrees it appears that the year is to begin at the midnight of Paris Observatory which precedes the true annual equinox. It is to consist of 365 days, with 12 months of 30 days each (the 80 days being 0 decades of 10 years each). This year was to be divided into 366 days, the 365th being called saniesudities (a name afterwards repealed). A sixth complementary day was to be added, not according to any rule, but selon la déclaration de l'Empereur le conscript: and although it was stated that it would be necessary to add this 366th day once in four years, yet it is not even stated in what particular coming years the necessity
would arise. The first decree, dated October 5, 1798 (the new month not having been introduced), declares the year then current to be the second year of the French republic, and enacts that An I began with September 22, 1792, and An II with September 22, 1793, and so on. The second decree, fixing the months, is dated the 4th of Frimaire, An II. (November 24th, 1798). The Gregorian reckoning was restored from and after January 1, 1806, by an imperial ordinance, dated 22 Fructidor, An VIII. (September 9, 1805).

It is to actual usage then that we must appeal to know what the decrees do not prescribe, namely, the position of the leap-years. For though every period of four years was a Frimaiced, and the last year of the Prairial (March 23, 1799) is described as a leap-year (having six complementary days), yet in fact An IV., An VIII., &c., are not leap-years. The following list, actually made from the work above mentioned, must be used as a correction of that in Yass, P. C. For various matters connected with the public-debt, &c., it was necessary to construct the table up to An XXII.

When the Gregorian year is not leap-year the beginning of the months are as follows, according as the republican year begins on September 22, 23, or 24:

- Vendémiaire is Sept. 22, 23, 24
- Brumaire is Oct. 22, 23, 24
- Frimaire is Nov. 22, 23, 24
- Nivose is Dec. 22, 23, 24
- Pluviose is Jan. 22, 23, 24
- Ventose is Feb. 22, 23, 24
- Germinal is March 22, 23, 24
- Floréal is April 22, 23, 24
- Prairial is May 22, 23, 24
- Maisondieu is June 22, 23, 24
- Thermidoria is July 22, 23, 24
- Fructidor is Aug. 22, 23, 24
- Jan. is Niv. 12, 13, 14
- Feb. is Pluvi. 13, 14, 15
- March is Vent. 14, 15, 16
- April is Germ. 15, 16, 17
- May is Flor. 16, 17, 18
- June is Prair. 17, 18, 19
- July is Therm. 18, 19, 20
- Aug. is Thermid. 19, 20, 21
- Sept. is Germ. 20, 21, 22
- Oct. is Flam. 21, 22, 23
- Nov. is Brum. 22, 23, 24
- Dec. is Frum. 23, 24, 25

But when the Gregorian year is leap-year the beginning of the months are as follows, according as the republican year begins on September 22, 23, or 24:

- Vendémiaire is Sept. 22, 23, 24
- Brumaire is Oct. 22, 23, 24
- Prim. is Nov. 22, 23, 24
- Nivose is Dec. 22, 23, 24
- Pluviose is Jan. 22, 23, 24
- Ventose is Feb. 22, 23, 24
- Germinal is March 22, 23, 24
- Floréal is April 22, 23, 24
- Prairial is May 22, 23, 24
- Maysolidieu is June 22, 23, 24
- Thermidoria is July 22, 23, 24
- Fructidor is Aug. 22, 23, 24
- Jan. is Niv. 12, 13, 14
- Feb. is Pluv. 13, 14, 15
- March is Vent. 14, 15, 16
- April is Germ. 15, 16, 17
- May is Flor. 16, 17, 18
- June is Prair. 17, 18, 19
- July is Therm. 18, 19, 20
- Aug. is Thermid. 19, 20, 21
- Sept. is Germ. 20, 21, 22
- Oct. is Flam. 21, 22, 23
- Nov. is Brum. 22, 23, 24
- Dec. is Frum. 23, 24, 25

For instance, what is 14 Floréal, An XII. The republican year begins Sept. 24, 1803, so Floréal falls in 1804, which is Gregorian leap-year. Look at the third Table, and when the year begins Sept. 24, the first of Floréal is April 21; consequently, what is 14 Floréal May 4, 1804. Again, since it lies by 1800, in the French calendar? The year is not Gregorian leap-year; and An VIII. contains it, which begins Sept. 23. Look in the second Table, and in such a year it appears that June 1 is the 12th of Prairial; therefore June 17 is Prairial 28.

Kalugew is a considerable island in the circle of Mesen, in the Russian government of Archangel, and situated on the north of the polar circle of, and they are between 68° and 69° 40' N. lat., and 47° 30' and 48° 10' E. long., and is about 60 miles in diameter. The surface is undulating; it has some low mountains, which rise in the centre, two small rivers, and several brooks of fresh water. The surface is covered, as in Mesen, with mosses; there are extensive morasses; the ground bears nothing but berries, some antiseptic plants, and stunted bushes. The surrounding sea is shallow, but swarms with fish; the coast abounds in seals, walruses, and other such animals. The cliffs are covered with an incredible number of sea-birds; the interior is full of polar bears, foxes, &c. Except a few Samoïdes there are no settlements of men in this island, and none but themselves here in the 18th century: but soon left the island. At present it is only frequented by fishermen and seal-hunters from Mesen and Archangel. The little island of Ploki-Bulak, Korsakov, and some others are near to it, but not in this year, and the natives are always industrious. (Hassel, Handbuch, vol. xi.; Cunnath, Lehrbuch.)

Kalumia, a genus of plants named by Linnaeus in honour of Peter Kahl, professor at Abo in Sweden. It has a small five-leafed, rather glandular corolla, with an angular or open limb having ten niches in its sides. The capsules five-celled and many-seeded. The species are evergreen shrubs with alternate or verticillate leaves.

K. laefolius has its leaves on long petioles, scattered or throng in a whorl, smooth and green on each side. It is a native of N. America from Canada to North Carolina, on the sides of stony hills. It has various names in the United States, Blue-wood, Calico-wood, &c. The flowers are red, and when in blossom have a very elegant appearance. The leaves of this species are said by Barton to be poisonous to man and beast, but their action can be feeble and unimportant, for animals are known to feed on the plant without any evident effect. Bigelow however states that the flesh of pheasants having eaten this plant has produced some cases of severe disease attributable to this cause alone. The flowers of the K. laefolius cause a large quantity of sweet nectarous juice, which is greedily collected by bees and wasps, but the honey formed from it is injurious to man, and the juice, if swallowed itself, will produce an intoxication of an alarming kind. Its leaves, when dried which adheres to the shoots and branches is used as a staunching remedy by the Americans.

K. angustifolia, Haulm-leaved Kalumia, has petiolate leaves, scattered or three in a whorl, oblong, obverse, rather rusty beneath, with several lateral, broad, lance linear, those at the base clothed with glandular pubescence. It is a native of North America from Canada to the Carolinas, in bogs and swamps, and sometimes in dry mountain lands. It is a shrub one or eight feet in height, with dark red flowers. It is called Shoon-Laurel in North America, as it is supposed to be very injurious to sheep. Several varieties of this plant with lighter and darker yellow flowers have been described. There are several other species, all of them natives of North America. They are all remarkable for the irritability of their stamens, and each of the stamens has a little cavity formed for it in the corolla, to serve as a protection to the anthers.

They are handsome shrubs when in blossom, and are great favourites in gardens and shrubbery. They grow best in a peat soil, or they may be planted in a very sandy loam or vegetable mould. They may be propagated by layers or seeds. When the seeds are used they should be sown early in the spring in flat pans or pots filled with peat earth, and very slightly covered over; the pots may be then set in a close frame, or in the front of a hot-house, till the plants come up, which may be transplanted to other pots, which should stand in a close frame till they have struck root; they should then be hardened to the air by degrees.

(Bom. Gardener's Dict.; Burnett, Outlines of Botany.)

Kather. Guy, an English mathematician of some eminence, and an excellent practical philosopher, was born at Bristol, April 16th, 1777. But of his early life very little is
K A T

135

KEA

known. He obtained a commission in the army; and in
1805, while holding the rank of lieutenant in the 12th regiment
(Cape Regiment), he became a member of the Royal Military
College, Sandhurst. During his residence at that institution
he was promoted to a company in the 62nd regiment; and on quitting
the College he received a certificate of his having passed the
first class. He was afterwards made brigade-major of the
eastern district.

Captain Kater was first engaged in making experiments to
determine the relative merits of reflecting telescopes con-
structed of an inch of glass, and in 1781 he published his
conclusions and his conclusion was that the ratio of the illuminating
power of the former to that of the latter kind was as 24 to 1. On this
subject he wrote two papers, entitled 'On the Light of the Cassiopes,
Large One and Small One' which were published in the 'Philosophical
Transactions' for 1781.

The determination of the precise length of the seconds
pendulum, an object of such importance in physical science,
engaged the attention of Captain Kater during several years.
The methods which had previously been employed to deter-
mine accurately the centre of oscillation in an irregular and
heterogeneous body vibrating as a pendulum were found
totally inadequate to this purpose; but Captain Kater suc-
ceded in surmounting the difficulty by availing himself of a
property of that centre which had been demonstrated by
Huygens, viz., that it was equal to the point in a suspended
body be made the point of suspension, the body will perform a vibration about it in a time equal to that
in which it performs a vibration about the original point of
suspension, if the rotation of the earth is considered. Experiments
mentally obtained, is evidently equal to the length of a
mathematical pendulum vibrating in the same time as the
given pendulum. The knife-edge mode of suspension of the first use
by his friend Dr. Farewell; and the details of the
construction of the pendulum are contained in a paper
which was published in the 'Philosophical Transactions' for
1818. (Pennell, P. C., pp. 408, 409.)

A bill having been introduced into parliament for estab-
lishing a uniform system of weights and measures in this country,
Captain Kater distinguished himself by the experiments which
he had made to ascertain the length of the seconds' pendulum, for
the purpose of assigning the physical value of the English
foot; and these experiments gave for the length of such pen-
dulum, in London, in vacuo and when reduced to the level of
the sea, 39-13999 inches. At the request of the Royal Society
of London, Captain Kater proceeded, with the instruments,
in July, 1818, to Dunmose in the Isle of Wight, to Arbory
Hill, Clifton, Leith Fort, Portsoy, and the island of Unst,
which he had with an adventuress of the more important
presumably for those places the several lengths of the
seconds' pendulum: an account of the experiments, with the
computed results, was published in the 'Philosophical Trans-
sactions' in 1819 and 1820. Here is said of Clairaut's
dimension, the diminution of terrestrial gravity from the
deck to the equator; and the great accuracy with
which the force of gravity may be determined by means of
his pendulum suggested to him the hypothesis of
a Swedish count: as the story, however, though often repeated, does not appear
to be sufficiently authenticated, an allusion to it is sufficient.
The account of 'her which appeared in Huber's 'Manuel des
Amateurs,' &c.'

In 1819 Captain Kater received, by the author of
the 'Philosophical Transactions', a small MS. volume entitled
'the Principles of Mechanical Science,' a work
published generally. To these attractions must be attributed
her success, for as a painter she did nothing of value beyond
an elegant female portrait, or an occasional female figure.
Her compositions are deficient in every essential quality of
art; in drawing she was extremely feeble, and her male
and female characters are not otherwise different than in costume.

(Goethe, 'Winkelmann und seine Jahnhunderl; Florilo,
Geschichte der Zeichnenden Künstler in Deutschland, &c; 
Nagler, Künstler-Lexicon.)

KEAN, EDMUND, was born about 1787, in London. His
father, Edmund Kean, seems to have been a stage-carpetenter;
his mother was Miss Ann Carey, daughter of George Savile
Carey, and grand-daughter of Henry Carey. (Carry, 
Henry, P. C. S.) George Savile Carey, who was born in
1745 and died in 1807, supported himself by dramatic public
lectures interspersed with the publication of various papers,
&c. He was the author of many songs and nine dramatic pieces. Miss
Carry was an actress at minor theatres and with strolling
players and in shadow shows. The Gordon's father shocked
her, and in 1808 he was married to Miss Carey, took
her name, and, probably from this circumstance, was
reported to have been his mother. He was sent to one
or two day-schools in London, but, as may easily be supposed,
KEA

KEA

got little literary instruction. His theatrical education, however, commenced early; Miss Tisdale instructed him in her art, and his mother, as soon as she found that he might be made useful, took him with her in her occasional occupation of selling flowers and perfumery from door to door, the beauty and value of which were much heightened by the story of his being the son of a tailor and the mother; she afterwards took him with her in her rambles with strolling players and showmen. Master Carey, as he was then called, was so clever, that once, when Miss Tisdale and Mrs. Quick moved to London in 1760, he was left at Wrexham with the tailor's son, the actor (the Richardson so well-known for his annual exhibitions at Bartholomew Fair), Master Carey was required to give his recitations before George III. at the Castle, which he did to His Majesty's satisfaction, and with such good effect that he was afterwards raised to the stage, and made a valuable addition to the company. He continued his performances, sometimes with his mother and sometimes alone, at small places of public amusement in London and the neighbourhood till about the age of sixteen, when he left her entirely, and joined a company of strollers in Scotland.

Kea's first performance of a complete character was that of Young Norville, in "Douglas," in Richardson's booth; his first engagement with a regular company was in 1804, when he made his appearance at Sheerness on Easter Monday, on which occasion he played George Barnwell and Harlequin in a pantomime. He was then called Samuel Keaveney, his salary was 8./.-per week. From time to time till 1814, when he made his first appearance at Drury Lane Theatre, London, his life was a series of the vices and virtues, struggles, and privatists incident to the profession of his country and theatre. In 1808 he began to appear at the Haymarket with Miss Cunard, the same company in which he had obtained an engagement at Gloucester. Maria Chambers, in July, 1808, became the wife of Kea; he then treated himself, and when she was near her accouchement with her first child they travelled together on foot from Bristol to Swansea, about one hundred and fifty miles, with only four pounds to pay their expenses on the road. On the 13th of September, 1808, Howard Kea was born. In the winter of the same year they passed over to Ireland, and at Waterford Kea became acquainted with Sheridan Knowles, then an obscure actor, and of that character, according to the newspaper report, his wife, Ann Betty, the Young Roscius, he disappeared till after Master Betty had gone away. One of Kea's best engagements was at Exeter, where his salary was £2 a week, for which he not only paid the leading characters, but also the scenery, properties, and orchestra, but Harlequin in the usual pantomime and the monkey in "Peroise."

While Kea was residing at Exeter, in 1813, he engaged to play four nights at Teignmouth; having completed his engagement, he had a benefit, on which occasion he played Rolla in "Pizarro," and then there was "Chiron and Achilles," in which his son Howard performed, and lastly there was a pantomime, in which he essayed his usual grace and agility as Harlequin. On this occasion Dr. Drury, late head master of Harrow School, happened to be present, with his wife. On the following morning Mrs. Drury called to pay for the tickets, and the Drury turned up to Dr. Kea's performances, and intended to speak to Mr. Pascoe Greenfield, one of the Drury Lane Committee, in his favour. In November, 1813, while playing to a very thin audience at Dover, a gentleman who was very attentive to his performance, and who seemed to admire it, but who did not applaud. Kea saw that he was appreciated, and played his best. The gentleman was Mr. Arnold, manager of the Theatre. On the following morning Mr. Arnold engaged him provisionally on behalf of the Committee of Drury Lane Theatre, for three years, at a salary of eight, nine, and ten pounds per week for each successive year.

At this time Kea was, Mr. Elliston had offered him an engagement at St. a week to play at the Olympic Theatre, in Wych-street, London, but the engagement had never been completed, and Kea thought no more about it. When he came to London however, andElliston heard that he was to be brought out at Drury Lane, he chanced his man, appealed to Mr. Arnold, and threatened to appeal to the law, the consequence of which opposition was that from henceforward the price of the ticket was to be increased. In 1814, poor Kea and his wife and child were almost famished, not having received a shilling of salary, except £5, which were sent to him at Dorchester to pay their expenses to London.

At length, after some urging, the manager suggested that the play-bills of Drury Lane announced "The Merchant of Venice," "Shylock by Mr. Kea, from the Exeter Theatre."

There had been no previous polishing, and the house was first tried, and he was immediately attracted. He played with such a success that the character; the house was well filled, and his fame was thereupon established. On his first night 16/. were paid at the doors; on the second, 294/; afterwards the average was upwards of 500/. His performance of Othello on one occasion brought 675/. 18z. 6d. After his third performance of Shylock, Mr. Whitbread invited him to breakfast to complete his engagement for three years, at £5. 5s. 6d. a week. Immediately after the contract was signed Mr. Whitbread tore to pieces in Kea's presence, and presented him with a sketch of a new engagement, by which the Drury Lane company were bound to employ Kea and pay him 200/- per week. Not long afterwards the Committee made his present of 800/, and he received many valuable presents from individuals. Drury Lane Theatre was saved from the ruin which had previously threatened it, and rapidly advanced to a state of prosperity.

Kea's career of success, including a visit to America in 1820, was uninterrupted till his criminal connection with the wife of Alderman Cox led to a subject commitment in the newspapers. On the 17th of January, 1825, the actor of Cox v. Kea was tried, and a verdict of 800/. damages was pronounced against him. Some of the newspapers made a series of comments on unusual severity on his private character. The public were exasperated against him, and he was driven from the stage of Drury Lane and afterwards from that of Edinburgh. After some time however he was allowed to go on with his performances, but Drury Lane box-office failed to reinstate himself in his former position, and therefore gladly accepted an invitation to pay a second visit to America.

After an absence of two seasons in the United States Kea returned to London, having during the time not only acquired but saved a considerable sum. The London public had relinquished their animosity, but it was in vain. He always had, in the time of his prosperity, been a dissolute man, but he had now fallen into habits of almost constant intemperance. His constitution was broken up, his memory was impaired to such a degree that he could not study a new part, his alacrity of spirit was gone, and his performances were little better than a repetition of those he had performed before the young Roscius, he had separated from Mrs. Kea after the trial with Alderman Cox, and allowed her 500/- a year; his mother was alive, in 1832, and had from him an allowance of 500/, a year. His eldest son, Charles, was at Eton College, and when Kea found that he was disposed to become an actor, he absconded with him, and abandoned him, and the young man was obliged to take to the stage in order to obtain the means of subsistence. Charles Kea was a year or two in America; after his return his father became reconciled to him, and in 1833 it was announced that Kea would play Othello, at Covent Garden Theatre, and that Charles Kea would play Iago with him. Kea struggled through the part as far as the speech "Villain, be sure," when his head sunk on his son's shoulder: he was borne off the stage, and his acting was at an end: the audience in kind¬ness immediately made it known to the managers. Kea lingered on at his residence at Richmond for a while, and before he died wrote to his wife to ask her to forget and forgive. She immediately came to him, and attended him till his death. The son, Charles Kea, took the boldness who were very attentive to his performance, and who seemed to admire it, but who did not applaud. Kea saw that he was appreciated, and played his best. The gentleman was Mr. Arnold, manager of the Theatre.
family were retired to rest, he would act scene after scene before them, illustrating the principles by expression of countenance, gesture, emphasis, and modulation of voice, the effect which his conception of the character required.

Keill was indisputably the greatest tragedian of modern times, and the acting of his characters is still remembered. In Othello, in truth and vigour of conception, in brilliance of execution, and power of effect, was entitled to rank with the best of Mrs. Siddons's performances. It was an exhibition of everything that could be desired from the actor, and also a display of his overpowering energy and pathos, and acknowledged by a series of bursts of applause the intense sympathy which he had infused into all ranks of society and all degrees of intelligence. The scene of the murder of Fortunatus, with a comparison of the parts of other characters he exhibited the striking points rather than the whole of the character; but this prologue did not apply to his Othello. Richard III., Shylock, and Sir Giles Overreach. These characters were all permed with an intensity of passion which he exhibited with matchless energy and truth. His power indeed was in the display of character and passion in all their varied shades. In passages of declamation he had peculiarities of intonation and utterance which gave him a strong and by no means pleasing mannerism. His comedy appears to have been by no means equal to his tragedy. He played Abel Druggar on one occasion for the benefit, and though it was well received, he did not repeat it. Old Mrs. Garrick, who witnessed it, and who admitted that he rivalled Garrick in Richard III., told him that his Abel Druggar was decidedly inferior to his husband.

Keill's accomplishments in arts connected with his profession were very varied. His fencing was much admired for skilful play, but he had a dislike for the pike. He played well on the pianoforte, and sang with exquisite taste and expression.

Of his private character little favourable can be said, though, if the circumstances of his early life be considered, much may be offered in excuse. He was profusely extravagant, spending the vast sums which he received in personal gratifications, and habitually indulging in dissipation among low society in taverns which were kept open to a late hour in the neighbourhood. He was beloved in his person, and not above the stress.

(Life of Edmmond Keill, London, 1835, 2 vols. 8vo.)

KEILL, JOHN, a distinguished British mathematician and natural philosopher, was born at Edinburgh in 1761, and having received the rudiments of education in that city, he completed his course of study in its university, of which the celebrated Dr. Gregory was then the mathematical professor. In 1784 he was entered at Balliol College, Oxford, where he distinguished himself by the lectures which he delivered in private on various subjects relating to natural philosophy, principally from the works of Newton; and in 1788 he published in London 'An Examination of Dr. Hume's Theory of the Origin of Man,' and in 1790 the same work in Dublin. In this work Keill pointed out, not without some hardness, the errors into which those theorists had fallen; and the severity of his strictures drew from each of them a reply: it is easy to see how the principal disputes of Newtonians with each other, as they are described at the side of Keill. In 1700 he was elected a Fellow of the Royal Society of London, and in the same year he succeeded Dr. Millington as Sedleian professor of natural philosophy. Two years afterwards he published a work in Latin under the title of 'Introductio ad veram Physicam,' which was well received in this country, and was also much esteemed in France—it being there considered as an excellent key to the 'Principia' of Newton. An examination of it in English was published in London in 1733, under the title of 'An Introduction to Natural Philosophy.' 8vo.

In 1709 Keill went to New England with the appointment of the principal of the College who were sent from America to the expense of the British government; these persons had been induced to leave Germany, and were living in London in great poverty: he returned, however, in the following year with the inhabitants of the Society for Promoting the Study of Astronomy at Oxford. In the year 1711 he was charged by Queen Anne with the duty of deciphering papers and it is mentioned as a proof of his sagacity that he once deciphered a secret of a fisherman. Very soon after, through the advice of Kames, the Scotchman, he wrote a little book on the national language. He held this post about five years.

In 1713 the University of Oxford conferred on him the degree of Doctor of Physic, and he published a small work under the title of 'Elements of Euclid, with a treatise on Trigonometry, and one on the Nature of Logarithms.' In 1718 he published a work entitled 'Introductio ad veram Astronomiam,' which he afterwards translated into English, under the title of 'An Introduction to the true Astronomy, or Astronomical Lectures delivered at Oxford.'

In the 'Philosophical Transactions' for 1708 there are two papers by Keill, one is on the Key Islands, and the other, 'Of the Laws of Centrifugal Force.' In the volume for 1713 there is a paper by him on 'The Newtonian Solution of the Vegetable Professor's Problems' and another on 'Theoremata quaedam Infinitarum Mathematicarum spectantia'; and one which is designated 'Observations on Mr. J. Bernoulli's Remarks on the Inverse Problems of Central Forces,' both of these were published in 'no Transactions' for 1714.

Dr. Keill died Sept. 1, 1721, in the fiftieth year of his age.

A writer in the 'Acta Eruditorum' having, in a notice of Newton's Treatise on the Quadrature of Curves, stated that the English philosopher had taken the Method of Fluxions from Leibnitz, the indignation of Newton's friends was excited; and in the paper on the Laws of Attraction, Keill, which, as above mentioned, was published in the 'Philosophical Transactions,' Keill formally asserted the claims of Newton to priority in the discovery. This paper gave offence to Leibnitz, who, in a letter to the Secretary of the Royal Society, required that Keill should be compelled to retract his assertion: this was not done; and Keill, in a letter to the Secretary, detailed the evidences of what he had stated. (Cogan, Dr. Samuel, Life of Mr. John Keill. 8vo.)

Dr. Keill was not fortunate on another occasion. Entering into the war of problems which was at that time carried on between the English mathematicians and those of the Continent, he somewhat presumptuously challenged John Bernoulli to determine the path of a body when projected in a medium which excited on it a resistance varying with the square of the velocity: the challenge was accepted, and before Keill could complete his own solution, Bernoulli announced that he had succeeded in obtaining one; the former was, in consequence, compelled to endure in silence the reproach which the foreign mathematician did not fail, unsparingly, to administer.

An edition, in Latin, of Dr. Keill's principal works was published at Milan, in 1742, in 4to., under the title 'Introductio ad veram Physicam et Astronomiam' (Huygens's Theorema de Vi Centripetae) quibus accedunt Trigonometria, de Virtutibus Centrifugis; de Legibus Attractionum.' (From the Philosophical Transactions.)

KEY ISLANDS are a group of islands of considerable extent in the Indian Archipelago, situated between 5° 20 and 6° 30' S. lat., and between 132° 30' and 133° 40' E. long. Three islands are rather large, and called Great Key, Little Key, and Banda Key. There are two others not known, as they are rarely visited by Europeans. They rise to a moderate elevation above the sea, and all the heights are overgrown with forest-trees, which constitute one of the principal sources of wealth. Dr. Keill was engaged in ship-building to a considerable extent; a great number of country vessels that ply between Borneo and Timor on the east, and the coast of Java on the west, are built on this island, especially in the harbour of Dool, which lies on the western coast of Little Key. These vessels are stoutly built, of excellent timber, and are sold for a moderate price. There is no town at Dool, but the harbour is large and surrounded by numerous docks. The native population of the island of Banda obtains from this place an abundant supply of provisions, especially cattle. The European and India goods obtained by this traffic are partly re-exported by the inhabitants to the Artoe Islands [Sunda Islands, vol. xiii., p. 291] from the harbour of Elle, which lies on the eastern shores of Great Key. This place is also remarkable for the manufacture of cocoa-nut, which is greatly prized by the inhabitants of the neighbouring groups, and preferred to all other utensils of that description. Many of the inhabitants are occupied with fishing trepang, and there arrive annually several vessels from Macassar to fetch the produce of that article. There are two languages spoken on the group, except that a part of them have embraced the Islam. This is especially stated of the inhabitants of Elle. It is further stated, that a great number of families from Banda and Ceram have set up their abode and migrated to the group, attributable to these foreigners that the native population has attained a higher degree of civilization than their neighbours.

VOL. II. T
KILIAN was born at Augsburg in 1679, and was educated as an engraver by his stepfather Dominicus Custos. He studied also the works of Tintoretto and Paul Veronese at Venice, after which he engraved several prints which were sold at Augsburg and obtained him the reputation of one of the best engravers of his age; his style of drawing was however not quite correct, and was somewhat mannered. He died at Augsburg in 1687. Lucas had great command of the graver, and has been known to execute two portraits in a week; his works are very numerous.

WOLFGANG KILLIAN was born at Augsburg in 1681, was also instructed in engraving by his stepfather Custos, and, as he was a very precocious artist, was sent by a gentleman to Venice. The prints there produced are the most correctly executed of his works. He was latterly compelled by the wants of a numerous family and hard times (it was during the Thirty Years' War) to seek more permanent sources of income, and, having married a woman of quality, he accordingly executed chief portraits. His greatest work is the Celebration of the Westphalian Peace in Augsburg in 1649, in two sheets, after a picture by Sandrart: it contains about five hundred portraits, and was executed at Augsburg.

BARTOLOMEO KILLIAN, the third son of Wolfgang, was born at Augsburg in 1680, and was first instructed in engraving by his father, who afterwards by his son's request went to study with Matthias Merian, a celebrated engraver at Frankfort on the Main. From Frankfort Bartolomaeus went to Paris, where he remained a few years, maintaining himself by his own labour; and he returned to Augsburg, where he was very able in all arts connected with the graver and the etching-needle. Sandrart terms him a born engraver: his works are very numerous, but are chiefly portraits. He died at Augsburg in 1696.

PHILIP ANDREAS KILLIAN, the son of Georg Killian, closely related to the above, was born at Augsburg in 1714, and was taught engraving by G. M. Preissler in Nürnberg. He studied also in the Netherlands and in various parts of Germany, and became one of the most distinguished artists of his time; besides his technical skill in the use of the graver he had a good taste and was a correct draftsman, but his execution is somewhat peculiar and monotonous. In 1744 Augsburg, the principal city of Poland, engaged his services, invited him to reside in Dresden, but Killian preferred his native city. He however visited Dresden in 1751 for the purpose of conducting the execution of a series of mezzotints of the chief artists who had resided at Dresden before his time, and is said to have improved pictures in the Dresden Gallery—Recueil d’Estampes d’aprés les plus célèbres Tableaux de la Galerie de Dresde.' The completion of this collection was interrupted by the breaking out of the Seven Years' war, in 1756. Upon the cessation of this work he commenced an extensive series of illustrations of the Bible in quarto, which he accomplished by the assistance of various other artists, to the number of 150 prints, but they are not among his best works. He executed many portraits; two of the best of which are the emperor Francis I, and Maria Theresia, after G. von Mytens. Three days before his death he was engaged on a portrait of Pope Clement XIII, which he very nearly completed. He died in 1759.

Heineken enumerates twenty-one members of this family, of whom eighteen were artists, and fourteen of these engravers.

(Koll, Reise door den weinig bekenden zuidelijk Molucken Archipel.)

KILLIOW, THOMAS, a younger son of Sir Robert Killigrew, was born at Hanworth in Middlesex, in 1611. He travelled in his youth, was present at an exercitum of the mus of Loudun, was appointed a page of honour to Charles I., and subsequently served under Charles II. in the Netherlands. He was Killian's court engraver, and invited him to reside in Dresden, but Killian preferred his native city. He however visited Dresden in 1751 for the purpose of conducting the execution of a series of mezzotints of the chief artists who had resided at Dresden before his time, and is said to have improved pictures in the Dresden Gallery—Recueil d’Estampes d’aprés les plus célèbres Tableaux de la Galerie de Dresde.' The completion of this collection was interrupted by the breaking out of the Seven Years' war, in 1756. Upon the cessation of this work he commenced an extensive series of illustrations of the Bible in quarto, which he accomplished by the assistance of various other artists, to the number of 150 prints, but they are not among his best works. He executed many portraits; two of the best of which are the emperor Francis I, and Maria Theresia, after G. von Mytens. Three days before his death he was engaged on a portrait of Pope Clement XIII, which he very nearly completed. He died in 1759.

fessional learning necessary for his new duties. He resigned the seals on the 26th of November, 1753, and died at his seat, Berwick, on the 27th of December. Anne, his wife, daughter of Richard Seys, of Boventer in Glou- 

KING'S COLLEGE, CAMBRIDGE, was originally a foundation for a rector and twelve fellows, founded by King Henry VI. in 1440, but in 1444, by a charter of Henry VI., it was endowed for a provost, seventy fellows and scholars, three chaplains, six clerks, sixteen choristers, and a music-master (who is now also organist), sixteen officers of the foundation, two hundred and sixty members of the students, and a large sum of money. Eton College was founded by Henry VI. in 1441, and when he re-founded King's College in 1448 he placed it in immediate connection with Eton College for the supply of scholars, each of whom at the end of three years from the day of his admission to King's College, is either elected a fellow or is no longer a member of the College. For the last twenty years the wants of King's College have been on an average less than four in the year. The process of electing the scholars on the foundation at Eton College for admission to King's College is described under ETON COLLEGE, P. C. S.

KING'S College has some peculiar privileges. The provost has absolute authority within the precincts; the undergraduates (under certain restrictions) are exempt, within the limits of the college, from the power of the proctors and other university officers, and from being imprisoned. The master of the college is an absolute authority in all matters, and the college is in no sense a corporation. The college is also the only body in the city which has a bridge, called the Bridge of Bells, in its name. The college is not only the only body in the city which has a bridge, but it is also the only body in the city which has a bridge of its own. The bridge is called the Bridge of Bells, and it is said to be the only bridge in the world which has a bridge of its own.

The original buildings of King's College consisted of the present chapel and a quadrangular court to the north of it, built of stone, 120 feet in length by 90 feet in breadth. The buildings of the college were constructed by Dean Thurlow, and were much decayed, it was determined that a large quadrangle should be erected to the south of the chapel; Gibbons was appointed the architect. The building was commenced in 1746, and was completed in 1752. The quadrangle is 280 feet in length by 270 feet in breadth, and consists of the Hall, Library, Chapel, and apartments for the fellows and scholars. It is separated from Trumpington Street on the east by a screen, in the centre of which is the entrance-gate. Beneath a domed tower, on the south side of the quadrangle, is 102 feet long, 36 feet wide, and 45 feet high, a noble room with a beautiful timber roof, similar to that of crostall Hall in London, the arched terminus in perfume. It is adorned with elaborate tracery. There is a music-gallery at each end, and an elegant screen at the west end. The roof is surmounted by two stone lantern-towers, and there is an oval window filled with stained glass, to which is attached a statue of a man, which is said to represent the founder of the college,—King Henry VI. It was built in 1447, and is now 250 years old. There is also a statue of a woman, which is said to represent the first woman who was admitted to the college,—Queen Elizabeth.
The charter precludes, in the following terms, persons who are not matriculated students in the university or college: 'Provided always, that no person who is not a member of the United Church of England and Ireland, as by law established, shall be competent to act as a governor by virtue of this Act, or to be a member of the council, or to fill any office in the college, except only the Professors of Oriental Literature and Modern Languages.' King's College is here intended to be exclusively a Church of England institution; and in this respect only does it mainly differ from University College, London, which was established in 1825. There was a design of affording the advantages of a college education to persons who were not excluded entirely or partially from the universities of Oxford and Cambridge, on account of their not being members of the Church of England. [University College, London, P. C.].

The visitor appointed by the charter is the Archbishop of Canterbury for the time being, and the governors, ex-officio, are the Lord Chancellor, the Archbishop of York, the Bishop of London, the Lord Chief Justice of the Queen's Bench, the Secretary of State for the Home Department, the Speaker of the House of Commons, the Lord Mayor of London, and the Deans of St. Paul's and Westminster. There are also life-governors, but their number is limited to twenty. The council consists of the governing sans and the treasurer, and a number of others. The proprietors are those who hold shares or have been donors to the amount of $300. Proprietors are entitled for each donation of $300 or upwards, to nominate a student, either for general or medical education in the college, and one pupil in the school, or two pupils in the school. The chief officer of the college is the Principal.

The college was opened in 1831. There are five departments: the Department of General Literature and Science; the Department of Applied Sciences; the Medical Department; the Theological Department; and the School.

In the Department of General Literature and Science, matriculated students, not under the age of 16 (except in special cases), are admitted to a regular and prescribed course of general study, but are allowed to attend any particular lectures not prescribed in that course. Occasional students are admitted, who attend any particular course or courses of lectures given in the college. There are apartments fitted up in the college for a limited number of students not under eighteen years of age, who are required to dine in hall. The prescribed course of study comprises religious instruction according to the principles of the Established Church; the Greek and Latin classics; mathematics; English Law and Jurisprudence. The modern history and geography of the world, as well as the French language, are taught. In the School, the course of study is given to pupils of both sexes, and consists of lectures and weekly examinations. All matriculated students are required to attend chapel daily, and a register of attendance is kept. The School is conducted on the same principles as those of the Michaelmas, Lent, and Easter Terms. Examinations take place at the end of the Michaelmas and Easter Terms, when the students are assessed according to proficiency. The school fees of those attending the School shall be paid for the following year annually, and the fee for the following year annually, and the fee for

There are several small endowments by benefactors of the college. The Worsley endowment is for the instruction in every department of two scholars, to whom a stipend of 25l. a year is paid, and who, on the completion of their studies, are sent out as missionaries; and there are several others for scholarships for pupils of the college. There are scholarships have been founded for matriculated medical students. The Master and Fellows of Magdalene College, Cambridge, have given an exhibition for students of the College. In 1835 the Rev. Mr. M'Neice, of St. John's College, Cambridge, bequeathed about 5000 guineas, chiefly in Oriental literature and philosophy.

King's College forms the eastern wing of Somerset House, which was built in an uncompleted state. In 1830 the government sold this site to the college for one thousand years, on condition that the proprietors completed the building in a style corresponding to the other part of the edifice. The college buildings extend from the Strand to the Thames. They comprise lecture-rooms, a chemical laboratory, a workroom, museums of anatomy, materia medica, zoology, botany, geology, and mineralogy, and libraries, besides a dining-hall, apartments for a limited number of students, and various offices. The school-rooms are in the basement story.

Kiva, Khiva, or Khwáy, a country in Asia, forming a part of that native division which goes by the name of Turkestan, or the Great Turkestan, is situated on the east of the Caspian Sea, between 38° and 48° N. lat., and between 43° and 53° E. long. Its political boundary is not distinctly determined, as it mostly runs through deserts, inhabited by nomadic tribes, which only nominally acknowledge the sovereignty of the Khans or pay obedience to their orders. On the east, the boundary between Khiva and Bokhara is more exactly fixed. It traverses the river Oxus a few miles north of the town of Chorab. The Oxus and river, which is the boundary between the Khivan and the Bokharan tribes of the Caspian. The Caspian constitutes its western boundary. On the south of Khiva is the desert called Dassh Jowz, and
through it lies the boundary-line separating Khryva from Persia and Merv. The authority of the Khan of Khryva may be considered to extend over 3000 square miles, or over 30,000 more than the extent of the British empire in Europe.

**Surface and Soil.** We begin with the wild latham, which lies between the Caspian and the Sea of Aral, and is divided into 43° and 45° N. lat., an extensive promontory projects into the Caspian. It is called Mangishlaik, and consists of a mountain-chain, divided into three chains, which according to an estimate, by a party under the command of the late Sir W. M. Lambuil, within 100 miles of the Caspian. From this place a mountainous country extends in a north-eastern direction towards the northern shores of the Sea of Aral; but with its nature we are totally unacquainted, as we lost our appropriation and could hardly expect to get to the table-land called Oost-cort. At this ascent the mountain-masses does not appear to be more than about 600 feet above the low steppe which extends along its northern base. The country south of this mountain-tract is unknown, with the exception of the eastern part, which is called Oost-cort, and which extends along the western shores of the Lake of Aral, to which it is bounded with steep cliffs. It is a table-land, about 600 or 600 feet above the sea, and consists of a barren and desolate appearance, which probably is the reason that it has no river or wells, though it is annually covered with a thick layer of snow, and hibernates more than undulating. The scanty vegetation consists mostly of single shrubs, and some few species of Chenopodiaceae, and at some places tracts several miles in extent are overgrown with Salix arbuscula, Lin., and Atrachis, as well as with the grass. The land, however, is a rare soil, and is entirely without vegetation. This table-land terminates on the east near 42° N. lat., but towards the Caspian it does not appear to go so far south, perhaps not farther than the Gulf of Kindeer (46° N. lat.).

To the south of the Oost-cort is a depression which appears not to be many feet above the level of the Sea of Aral. It begins on the east near Kara Oorgentch, where it is only a few miles wide, but it grows wider in approaching the lake of Kuli Daria, or Kara Bogaz, where it is more than twenty miles wide. The surface of this depression is covered with a minute sand, similar to that found at the bottom of the sea. It is therefore supposed by some writers that the river Oxus or Amoo Deria at some period sent its waters through this depression to the Kara Bogaz. This supposition is supported by the general opinion of the natives. The lake of Kara Bogaz receives its waters from the Caspian by a narrow strait, and they are therefore brackish. According to the best authorities, the lake is more than a hundred miles in length, and between twenty and thirty miles across. The lands and the adjacent countries are arid.

Above thirty miles from the lake, and south of it, is an isolated mountain-range running east and west. It extends along the northern shores of the Gulf of Balkhun, and is also said to extend along the same line, but on the north-east. The same mountain chain has a greater elevation, but north-east of the innermost recess of the bay are some summits called Great Balkan, which appear to attain an elevation of at least 2000 feet above the level of the sea. This is also the case with the mountains which extend southward, and encloses the bay also on the cast, where it is known by the name of Littino Balkan. At its southern extremity, south of 40° N. lat., another depression is said to exist, by which it is supposed that the Oxus may have discharged its waters into the Caspian, but this fact rests on information collected from the natives. Between 40° and 39° N. lat. the Caspian is skirted at a great distance from the shores by a chain of mountains, which do not appear to attain a great elevation. They are called the Lambuul mountains. At their southern extremity, near 39° N. lat., the third depression is said to occur. Farther south, to the boundary of Persia, or rather to the river Atreuck, and the Gulf of Hassan Kulli, an uninterrupted ridge of sand-hillsskirts the Caspian, about ten miles from its shores.

The mountain ranges which extend from the shores of the Caspian Sea to the vicinity of the river Oxus, south of the Kara Bogaz, is called the Desert of the Truchemenes or Turcomans. With the exception of the mountains and hills already noticed, it is a great desert, as the nobility of grass is scarce or entirely wanting. There are no large flat depressions, in which lakes are generally found, of which however the greater part is dried up during the summer. The northern part of it cannot properly be called a desert. There are few trees in the western part, but the vegetation is very extensive, and the remainder consists of a loamy hard soil, impregnated with salt, which in spring and the beginning of summer is partly covered with grass; but later in the season is without vegetation. In the hot season the sandy plains, and the bottom of the valleys, in which the leaves of the bushes and trees that grow in the depressions, or bring them to the boundary of Persia, or of the cultivated part of Khryva. The southern part however is almost entirely covered with sand. This tract is called Dariq or Daria, and is about 200 miles wide. The Oxus, called in Hind, 2000 feet above the sea, and of a width of thirty to forty miles, and its winds are large and numerous.

Khryva Proper, or the cultivated portion of the Khanat, consists of a comparatively narrow tract contiguous to the course of the river Oxus, and extending from Pitskun, the most southern town of the country, to the eastern bend of the river (north of 43°), a distance of about 150 miles. Its western boundary may be marked by a line drawn from the town of Khryva to that of Kara Oorgentch, which falls short of a hundred miles of the Confluence of the two rivers. The Oxus exceeds 30 miles, and the area of this tract falls short of 4000 square miles. It is not equal to double the extent of Norfolk. This tract is thinly inhabited, and produces almost every kind of grain in abundance. But its fertility is properly not derived from the soil, which, where it is beyond the reach of irrigation, consists of a hard loam, impregnated with salt, and nearly without vegetation. But the whole region is traversed by so many canals, that it resembles a net. The water is drawn from the Oxus, and runs with a perceptible current to the west and north-west, where the canals terminate in a series of lakes at the foot of sand-hills which divide Khryva Proper from the Caspian Sea. The Farmers of the Oxus are the Fath Mahomed Seik, and their produce consists of lucerne, which is enclosed by its arms, contains very little land fit for agricultural purposes. It is annually inundated by the river, and mostly overgrown with reeds and rushes, but there are considerable tracts which serve as pasture-ground for cattle, which is of great importance, as the southern country has no meadow land or pastures. Where the delta borders on Lake Aral, it is a complete swamp all the year round. This country is so low, that probably the whole delta would be laid under water if the level of the Sea of Aral were raised a few feet.

On the east of the river Oxus the cultivable ground is of small extent. About 42° 20' N. Lat., begins a tract of higher ground about two miles from the river, which runs parallel to it for about forty miles to the south-east. This ridge is about four miles wide, and is called Shikochodshel; it rises about 600 feet above its base, and descends gradually eastward into the Desert of Kizil Cun. Where this ridge terminates (40° 32'), the cultivated land probably extends to five or six miles from the banks of the Oxus, and here also there are several smaller canals.

**River and Canals.**—The river Oxus, whose modern name is Amoo Deria or Gilson, originates in the elevated mountain region which divides Lower Turkestan from Chinese Turkestan, and which, as was mentioned before, issues from a lake, called Sini-kol, which is about fourteen miles long from east to west, with an average breadth of one mile, and near 37° 27' N. lat. and 70° 40' E. Long. Tsin mentions the fact that in old times, the river Oxus to the east, but turned southward, and encloses the bay also on the cast, where it is known by the name of Littino Balkan. At its southern it is, south of 40° N. lat., another depression is said to exist, by which it is supposed that the Oxus may have discharged its waters into the Caspian, but this fact rests on information collected from the natives. Between 40° and 39° N. lat. the Caspian is skirted at a great distance from the shores by a chain of mountains, which do not appear to attain a great elevation. They are called the Lambuul mountains. At their southern extremity, near 39° N. lat., the third depression is said to occur. Further south, to the boundary of Persia, or rather to the river Atreuck, and the Gulf of Hassan Kulli, an uninterrupted ridge of sand-hills skirts the Caspian, about ten miles from its shores.

The mountain ranges which extend from the shores of the Caspian Sea to the vicinity of the river Oxus, south of the Kara Bogaz, is called the Desert of the Truchemenes or Turcomans. With the exception of the mountains and hills already noticed, it is a great desert, as the nobility of grass is scarce or entirely wanting. There are no large flat depressions, in which lakes are generally found, of which however the greater part is dried up during the summer. The northern part of it cannot properly be called a desert. There are few trees in the western part, but the vegetation is very extensive, and the remainder consists of a loamy hard soil, impregnated with salt, which in spring and the beginning of summer is partly covered with grass; but later in the season is without vegetation. In the hot season the sandy plains, and the bottom of the valleys, in which the leaves of the bushes and trees that grow in the depressions, or bring them to the boundary of Persia, or of the cultivated part of Khryva. The southern part however is almost entirely covered with sand. This tract is called Dariq or Daria, and is about 200 miles wide. The Oxus, called in Hind, 2000 feet above the sea, and of a width of thirty to forty miles, and its winds are large and numerous.
From Kilah Chup its general course is to the west for about two hundred miles, through a country where cultivated tracts alternate with sandy deserts of moderate extent. After having passed the meridian of Balkh (67° E. long.), its course declines more to the north-west, and in that direction it continues to the mouth of Khyva, traversing the adjacent country for more than two hundred and fifty miles. The country which it traverses is unfit for cultivation, except in the immediate vicinity of the river, where the fields are irrigated from it. At times there is still a mixture of sand and navigation, but not far from the boundary-line between Bokhara and Khyva, rapids are said to exist, which are full of rocks, and during low-water dangerous to be passed by boats. In this middle part of its course the Oxus is not joined by any permanent stream.

The lower course of the Oxus, from the above-mentioned rapids, above the Bokharian fortress of Charchi, to its mouth in the Sea of Aral, probably exceeds five hundred miles in length, so that its whole course amounts to nearly thirteen hundred miles. It therefore is larger than any river in Europe, except the Volga. Nearly two hundred and fifty miles of its lower course lie through a desert country, similar to that traversed by it in its middle course, but there does not occur any obstruction to navigation, and it is navigable. The river reaches Khyva from which it is distant 41° N. lat., and traverses it in one bed as far as *43° 20'*, or upwards of a hundred miles. It is course is by the northern extremity of Mount Shikhsulchhil to the west, and a few miles lower down the river divides into two arms, of which the smaller, the whole length of which is run in a westerly direction about fifty miles, when it falls into Lake Ak-Cheganak. This lake is situated near the base of the table-land of Oost-coert, and at a distance of thirty miles from the Sea of Aral. It extends about thirty miles from east to west. On its northern side begins a deep depression, which extends along the base of the table-land to the Sea of Aral, and has a mean bread of fifteen miles. It is entirely filled with water even in winter, when the level of the Oxus is lowest, but only to a moderate depth. It is overgrown with reeds, rushes and other aquatic plants, with the exception of a comparatively narrow strip in the rich an hundred miles from the mouth of the Oxus, which is stunted, and where the perceptible current runs to the Sea of Aral. The water of this swampy tract is sweet. Nearly halfway between the place where the Lowdahn branches off from the Oxus and its influx into Lake Ak-Cheganak, it sends off a branch to the south-west, which is called Staraksh, and passes near the town of Kana (Old) Oorgendah, but its farther course is not known. At Kana Oorgendah it was, in September, 1842, a river about sixty or seventy feet wide, and two feet deep.

From the place where the Lowdahn branches off the main stream of the Oxus runs due north about ten or twelve miles, and then sends off an arm to the north-east, called Kook-usak, which is one of the more than thirty small branches called Daukara. From this lake a swampy depression similar to that of lake Ak-Cheganak is stated to extend to the Aral; but this fact rests only on the information of the mountaineers of the Kara, which extends again north-west, and sends a branch, called Kara-Balik, to Lake Daukara, and two smaller ones, Kiatt Chargen and Kok-Daria, to the depression north of Lake Ak-Cheganak. farther on, at a distance of about thirty miles, the Oxus divides into two arms, of which the smaller and western, called Talidk Daria, reaches the Sea of Aral without dividing any farther, but the eastern, Ulu Daria, enters the sea by two arms, of which the eastern is six to seventy feet deep, and two feet deep, and that the place, which was formerly uninhabited, had again been settled, and contained a population of 1000.

A river like the Oxus, traversing such a level country as Khyva, must be subject to frequent and great changes in its course. The river, like the Nile, brings down during the freshets a great quantity of detritus; but, unlike the deposit which the Nile leaves on the field after having re-entered its bed, the earthy matter contained in the Oxus diminishes the fertility of the soil. To prevent inundations the banks of the river and of the larger canals have been raised considerably above the level of the country. The detritus is here and there intermixed with a kind of thin layer of mud mixed up with sand. The canals must annually be cleansed, and this is a laborious work. In spite of the embankments partial inundations are rather frequent, and destructive floods are apt to occur; for a considerable portion of the cultivated tract was laid under water, and it is stated that more than five thousand persons perished.
In this inundation. The level of the river is highest from May to July, and then its waters are very turbulent; but in the remainder of the year, i.e. from August to April, it runs with a considerable current, at least two miles an hour. Its depth varies between six and ten feet. It must be much navigated, as it is stated that there are more than a thousand vessels of different kinds on the river at one time.

No country in the world has so many canals as Khyva. The number of the larger canals is stated to exceed twenty. In the southern districts they run westward, but skither north to the northern territory and then run eastward again, in which, with the sand-hills contiguous to them on the west, separated the cultivated region from the Desert of the Truchmenes. Their width varies between seventy and a hundred feet, and their length is greater than can be properly estimated. The largest, is at least seventy miles long. From these larger canals others of minor dimensions branch off and water the country to the distance of twenty miles. The canal of Palwan has twelve lateral canals of which one-fourth exceed twenty miles in length and about six are more than fifteen miles long. The water of these canals is brought to the fields by ditches. During the frosty weather a considerable current runs through the canals, and even at other seasons it is perceptible.

The canals are still more navigated than the Oxus itself.

Climate.—The climate partakes of that excess of cold and heat which is peculiar to the country. It is distinguished above all other parts of the globe. We have no regular meteorological observations. On the 8th of October, 1842, the thermometer stood at 90° at two o'clock in the afternoon, and the cold increased so much in the evening that the same year it fell as low as 11° below zero of Fahrenheit. The summers are very dry; rains fall rarely, but gales are frequent. Frost is commonly experienced towards the end of October, and the lakes and canals are soon covered with ice. The Oxus however does not freeze before the end of the year. In the beginning of January, 1843, the ice of the river was found to be between thirteen and sixteen inches thick. Snow does not fall in large quantities, hardly more than four inches deep at once, and lies rarely more than four days on the ground, which is remarkable, if the frost is continuous. The climate is generally healthy; but in autumn fevers and agues are endemic.

Productions.—Agriculture is attended to with great care and industry; sometimes the fields are ploughed seven times. Great attention is paid to the preparation of manure. On the fields are cultivated rice, wheat, barley, millet, sesame, cotton, jugari (Helenium annuum), peas, lentils, hemp, poppy, and clover; in the gardens, melons and water-melons, pumpkins, carrots, turnips, peas, onions, potatoes, and cucumbers; in the fields, hay, flax, and grain. In the northern district, which is near the Caspian, there are many lakes, where ducks and geese are reared, and by which a considerable number of salmon are caught. Apricots, apples, pears, plums, cherries, and vine, also currants. But the fruits are not distinguished by flavour, except the melons and water-melons. On the banks of the canals and ditches are cultivated poppies, and, sometimes, large fields of hemp. The large poplar trees found on the banks of the Oxus are only found on the eastern banks of the Oxus. In the lower region a plant grows wild, whose roots, moraya, are used for dyeing red.

The Truchmenes are very beautiful, and hold in great estimation, especially those which are called argamaks. Common horses are brought to Khyva by the Kirghiz. Many camels are kept, even by the poorer people, and also asses. Few cattle are reared, on account of the want of meadows, except by the Karakalpakes, who import cows and oxen into the cultivated region. Sheep are reared by the Truchmenes, or imported from Bokhara, on account of the fleece: the Kirghiz import a considerable number for slaughtering. Fowls are numerous; but turkeys, geese, and ducks, are only kept by the khan. Water-fowl are numerous in the delta, but other wild birds are rare. Of wild animals there are but few, tame goats, jackals, hares, wild goats, deer, and wild hogs, mostly in the delta, where also the tiger is sometimes met with. Fish abound in the lakes, river, and Sea of Aral; but are not much eaten, except by the Karakalpakes, who are very fond of smoked fish. Silk-worms are reared to a considerable extent.

Gold and copper are said to exist in the Shihchodshili mountains, but are not worked. The other useful minerals are salt, asphaltum, and iron; the latter is worked by the Kirghiz. The stone quarries are near the alluvial soil, apri- cot, pears, and plums. Silk-worms are reared to a considerable extent.

Population and Inhabitants.—The whole population is estimated at 2,000,000, of which one-fourth are stated to be settlers in Khiva Proper; so that in that part of the country about one-third are Khyva, but still of semi-nomadic habits. The chibl are those of cotton, of which several kinds of stuffs are made by the Sartcs, who also work up all the raw silk made in the country, and they produce some very good articles. Worsted manufacturing is carried on by the Kirghiz, and worsted manufactures are exported to the countries of the Caspian. In some places are large manufactures of cotton-ware. Several utensils of copper are made in the country, but all articles of iron are imported, almost exclusively from Russia. In the west, the Kirghiz settled in the Khut for the exercise of the trade of blacksmiths,

Commerce. — In a country like Khyva, whose soil supplies its inhabitants abundantly with food, whilst its manufacturers afford a livelihood only to a small number of people, it is impossible for any article of exportation, foreign commerce must be very inconsiderable. The most active is that with Bokhara, from which place also a few Indian goods are imported. We have heard of a caravan going from the Aral Sea, to Kishinev, at the time of the conquests of Alexander the Great. After his death it was united to the kingdom of Syria, but separated from it by the revolution of Theodotus of Bactria (256 before Christ), who founded a separate kingdom in these parts. But in the second century before Christ the nomadic nations of Upper Turan began to move into the land of Turan, and took possession of the countries north of the Oxus and south of the Sea of Aral. They seem to have laid waste the country and kept possession of it for more than two centuries. In the second century our era, however, they were driven by the way of the Chinese emperors, who at that period extended their dominions to the shores of the Caspian. It is not known at what time and in what way the Chinese were compelled to abandon this country. In the third century of our era it was connected with Persia, and remained so up to the tenth century, when one of its governors acquired independence and erected the kingdom of Karizam or Khowvuram, which appears to have remained an independent state until conquered by Genghis Khan (1218). The descendants of Gengis Khan remained in possession of the country, which continued to form an independent kingdom under the name of Khowvuram, up to 1379, when the town was taken by Timour, and the country annexed to his possessions. Khyva remained a part of Mavral-enish, or the kingdom of Samarkand, to the beginning of the sixteenth century, when a Turkish nation, the Usbecks, under the suzerainty of Shiban Khan, descended from Upper Turkistan, and by degrees took possession of the whole of Turan. Khyva, as it appears, soon became an independent state under an Usbeck prince, and has remained so ever since. A few years ago the caravans passing between Orenburg and Bokhara, in travelling to the country east of the Sea of Aral, were frequently molested and robbed by the subjects of the Khan of Khowvuram, who knew that the Usbecks were unable to restrain the nomadic nations from attacking the caravans, they resolved on taking possession of the country; probably also with the view of extending farther their conquests in this disorganized country. They had the advantage of a surprise, and they were enabled to march up to Khyva, and when they arrived there it was found that one-third of the soldiers had died.

KLA 144

KLA

Your pardon," answered young Klapproth, "I know Chinese." His answer was received with astonishment and distrust, but he immediately gave proofs of his having made great progress in that difficult language, and he became henceforth an object of admiration to all who had an opportunity of witnessing his extraordinary talents. He had learned Chinese secretly and without the help of a tutor. People thus saying, he first began in 1797, after he had found out a small and incomplete, but nevertheless valuable collection of Chinese books in the public library at St. Petersburg. His father, however, perceiving that he devoted his time exclusively to Oriental languages, he sent him, in 1801, to the university of Halle, with a strict injunction to study the classics of the East. Klapproth had a love for Halle, and in 1802 published the first number of his "Asiatisches Magazin." The learned Count John Potocki having heard of Klapproth, hastened to make his acquaintance, and was so struck with him that he immediately proposed to him to enter the service of the emperor Alexander of Russia. Klapproth accepted the proposition, and the count being in great favour with the czar, Klapproth was formally invited to settle in Russia. On his arrival at St. Petersburg, early in 1805, the Academy of Sciences presented him with a diploma of Adjunct, for the Eastern languages and literature, and the Russian government gave him the title of architect, being the title of this description of the lands of Persia and Turan, Count Potocki obtained for Klapproth the place of an interpreter. Klapproth actually got his commission before the appointment of an ambassador. This honour was finally bestowed upon him, when he was transferred to the embassy at Pekin. Count John Potocki was put at the head of a body of scholars who were to accompany the embassy. Klapproth set out alone, before the embassy was ready to undertake the journey, and after having traversed the Altai Mountains, and passed through Katherinenburg, Tobolsk, and Omsk, employing all his time in studying the country and its inhabitants, he finally arrived at Irkutsk, which was the place of meeting for all the members of the embassy. Klapproth was received soon afterwards at Irkutsk and Kiashta, the embassy crossed the Chinese frontier on the 1st of January, 1806. They had scarcely proceeded a hundred and eighty miles when they were again detained, Count Golovkin having refused to submit to the Chinese court-ceremonial, and after having remained a month in a miserable Mongol town, the count was informed that the court of Pekin did not wish to see him. The embassy consequently returned to St. Petersburg. Klapproth however did not accompany them, but took a solitary route through Southern Siberia, and only reached the Russian capital February 1807, after a journey of six thousand leagues, of which he had written a separate narrative. He arrived in St. Petersburg, was received with distinction, and the emperor conferred upon him the title of Asiat. counsellor, and made him a knight of the order of Vladimir, an honour which placed him among the Russian nobility. However, Klapproth had expected still greater distinctions, and the Russian government having secretly put a stop to his intended publication of his journey through the Caucasus, he began to feel uneasy in Russia. He was too frank, too liberal, and too bold to feel happy among slaves. He nevertheless prolonged his sojourn in Russia, and was active in establishing a school of Oriental languages at Wilna, and in making a descriptive catalogue of the Chinese and Mandare MSS. in the imperial library at St. Petersburg. He was sent, in 1811, to Berlin, for the purpose of superintending the engraving of the characters which were intended for printing these MSS. In 1812 he tendered his resignation to the Russian government, and after a considerable time received his discharge, with the remark that by soliciting permission to retire he had forfeited all his civic and scientific titles and privileges in Russia. In St. Petersburg however there were strange rumours afloat as to the foreigner's intentions, and belatedly he was afterwards repeated in foreign countries, that his love of rare MSS. and books went beyond mere scientific attachment. No sooner was Klapproth free than he began to bring out his journal of travel, which was afterward published in the theatre of a long and bloody war, and the learned Orientalist
KLA

feld from place to place without finding repos for his pursuits. The Chinese went before him, and he spoke of distinguished men in the French armies, and his name became known to Napoleon. Klaproth's admiration for the French emperor must have been great, for after Napoleon had been exiled, Klaproth was one of the few who went to see the fallen hero in his exile. Napoleon received him very well, and it appears that Klaproth, expecting the emperor's early return to France, offered him its services, and was engaged in the event of his return. Napoleon is said to have given France. The 'hundred days' however passed away without any notice being taken of Klaproth, and when the Bourbons returned to Paris he was in Florence, in rather uncomfortable circumstances. Klaproth was the companion of Pells Monneret de Villard, who invited him to settle in Paris, and there Klaproth lived some time by his pen, when he accidentally met with William von Humboldt, who, although he had seen him only once, employed all his influence to procure for him a situation suitable to his pursuits and his merits. It was at Humboldt's recommendation that the late King of Prussia, Friedrich Wilhelm III., conferred upon Klaproth the honorary title of royal professor of Oriental languages and literature, which was accompanied with a liberal pension, and a promise to defray the expenses of printing whatever works the professor might think fit to publish. Klaproth was further allowed to stay in Paris as long as he pleased. Placed beyond all want, and moreover enjoying an income which enabled him to gratify his love of pleasure and refined society, Klaproth now exhibited an extraordinary activity, and it was in the years subsequent to this time that he raised the oriental studies of France to a position of high and respected eminence, and the discoveries which established his European reputation. The life which Klaproth led in Paris, leaving his study only to plunge into the torrent of mental and physical excitement of the gayest capital of Europe, proved fatal to his health. In 1833 the symptoms of the dropsey of the chest becoming alarming, a tour to Berlin, where he was received with great distinction by the king and the people, produced a good effect; but shortly after his return to Paris he fell ill, and bodily sufferings were unfortunately accompanied by occasional derangement of his intellectual faculties. The skill of the first physicians of Paris proved ineffectual, and after long and painful trials, Klaproth died suddenly, on the 27th of August, 1835, and was buried in the cemetery of Montmartre.

Klaproth was one of the best scholars and certainly the best linguist of an age which can justly boast of great linguists. His penetration and sagacity, and the quickness of his perception, were extraordinary; clearness and perspicuity distinguish his style; and his memory was so happy and capable of retaining the most different impressions without ever confounding them, that he seldom made more than scanty extracts. When he began a work, it was already clear and distinct in his mind, and the composition did not take him more than a few weeks. If we compare Klaproth with William von Humboldt, we find that Klaproth had the superiority in analytical power, while Humboldt surpassed Klaproth in the synthetical. Klaproth's brain was capable of more rapid and more extended combinations of ideas than Humboldt's, which was naturally of a kind disposition towards everybody. Yet this kind-man was the dread both of his literary enemies and friends. The former dreaded his answers to their attacks, and the latter observed the greatest precaution in their intercourse with him, lest they should irritate his irascible temper; and it would seem as if he made no distinction between scientific and moral error, so severely did he handle those who incurred his scorn through impiety of ignorance or insincerity in matters of learning. His controversy with Professor Schmidt, the Mongol scholar in St. Petersburg, is an instance of this.

It would take much space to give a complete catalogue of his numerous publications, especially as the majority of them consist of pamphlets, memoirs, and dissertations, many of which are not of any general interest. Previous to 1812 he has no published anything, and in the 'Jahrbuch der philologischen und historischen Literatur,' in 1812, being a German translation, with notes, of a Chinese inscription; and articles in different learned periodicals. The 'Reise in den Kaukasus,' with maps, Halle and Berlin, 1812-14, 2 vols. 8vo.; of these 'Travels in the Caucasus' a French translation, in 2 vols. 8vo., Paris, 1828; and in 2 vols. 8vo., 1832; 2, 'Execution d'Autunne (The Autumnal Execution), Peking, 38th Anniv. of King, 8th June, jour malheureux;' this severe critique of Weston's translations from French to English is of great value. In the Dictionnaire Chinois-Latin of Pate et M. de Guignies, Imprimé en 1813, par les soins de M. de Guignies, Paris, 1819, fol.; 4; 'Abhandlung über die Sprache und Schrifft der Uigurigen, 2nd ed., 8vo., 1818, translated into French and English, and this is a classification of the Asiatic nations according to their languages, with a comparative vocabulary of most of the Asiatic languages; 6, 'Examen critique des Extraits d'une Histoire de l'Inde, 1816, 8vo., 1823, 8vo., 7, 'Sur l'Origine du Papier Monnaié en Chine,' Paris, 1823, 8vo.; this very interesting treatise on the origin of paper-money was shortly afterwards translated into English. Paper-money was known in China as early as 119 n.c., and was in general use in the tenth century of our era, but it fell into disuse in the middle of the fifteenth century; Marco Polo mentions it 8, Tableaux Historiques de l'Asie depuis la Monarchie de Cyrus jusqu'a nos Jours,' with twenty-four maps, Paris, 1824-26, 9, 'Mémoires relatifs à l'Anie,' etc., Paris, 1824-28, 3 vols. 8vo., with maps and engravings; one of the most valuable works on Asia, 10, Dr. W. Schmidt's 'Angélique Universel, Bctriigerei,' Leipzig and Paris, 1823, 8vo.: 'Dr. W. Schmidt's alleged translation of the works of Confucius, from the language of China to their original Chinese, from the cabinet of M. de Guignies, a chain of letters, in 1826, 8vo., 11, 'Erläuterungen zu den Werken des Confucius aus der Umsprache, eine literarische Betrachtung,' Leipzig and Paris, 1825, 8vo.: 'Travels in Japan,' 1826, 8vo., 13, 'Pour st-Intelligence des Hiéroglyphes Acrologiques adressée à M. le Comte de Goullain,' Paris, 1827, 8vo.; 14, 'Chrestomathie Mandchou,' Paris, 1828, 8vo.; 15, 'Abrégé de l'Origine et des Diverses Civilisations des races humaines,' Paris, 1831, 8vo., 16, 'La Lettre sur les Découvertes des Hiéroglyphes Acrologiques adressée à M. le Comte de Goullain,' Paris, 1827, 8vo., followed by a 'Seconde Lettre' on the same subject, addressed to Mr. D. B., published in the same year; and, 17, 'Examen critique des Travaux de M. Champollion, jeune, sur les Hiéroglyphes,' Paris, 1832, 8vo. Klaproth is of opinion that although the younger Champollion deserves great credit for having improved and enlarged our knowledge of hieroglyphics, by correcting and extending the theory of Dr. Young, and discovering the significance of many new signs, yet Champollion's theory is only available for reading the names of kings and the names of persons, with respect to ideographical and symbolical signs, which, according to Klaproth, Champollion unsuccessfully attempted to decipher. The system of Champollion, says Klaproth, 'is not founded on any scientific principle; it is as if a person, whenever he think's fit, that significance which he laid down as the original meaning of the phonetical as well as symbolical characters. That scanty knowledge of the ancient Egyptian language which we have at present, is not enough to explain the degree of confidence which we can bestow upon the theories of deciphering hieroglyphics.' Klaproth, of course,
speaks of the state of knowledge of his time. 18. 'Notice d'une Mappemonde et d'une Cosmographic Chinoise, publiées en Chine, l'une en 1730, l'autre en 1739.' Paris, 1833, 8vo.; 19. 'Nipon o Del italienne, ou Annales des Empereurs du Japon, 1817-1833.' M. Isaac Tournefort, ed. and trans. by an original by M. Klaproth, and preceded d'une Histoire Mythologique du Japon,' Paris, 1834, 4to.

Among the publications edited or translated by Klaproth, we must mention the publications of the Asiatic Society of Paris, of which he was one of the founders; Gulfenstidt's Travels in the Caucasus; Count John Potocki's Travels in the steppes of Astrakan and the Caucasus; Father Della Penna's Travels in Siberia; a description of the same country, translated from the Tibetan language into Russian, and thence into French; Tinkowski's Travels to Pekin; 'Magasin Asiatique,' from 1825-27, &c. &c. Among his minor productions a letter to Baron Alexander von Humboldt on the invention of the Compass, and another on the art of printing and gunpowder, are both important and interesting. Klaproth's contributions to the learned periodicals of France, Germany, and Russia would fill more than twenty octavo volumes. Klaproth was not only an Oriental scholar, but also an excellent theoretical as well as practical geographer, as appears from Critical Observations on Arrowmith's Map of Asia; his 'Cours de Geographie,' d'apres les Etudes de M. l'Empereur Klaproth, Paris, 1835, in four large sheets: 'Carte de la Mongolie, du Pays des Mandchous, de la Coree, et du Japon,' Paris, 1835; and 'Memorial, or Sketch of the Policy, and Experience of M. Klaproth, left ready for the press 'Description geographique, statistique, et historique de l'Empire Chinois,' which was to appear in French and English, but has not yet been published. He published a MS. consisting of a plan of a 'Jardin Mithridatique,' and a Commentary on Marco Polo: both these works were completed in his mind, but as he was not in the habit of making many notes previous to writing, there is no hope of seeing these MSS. ever made ready for the press. A complete catalogue of all his publications is contained in Catalogue de la Bibliotheque de feu M. de Klaproth, par le Libraire Merlin, Paris, 1839, 8vo. ('Notice de M. le Professeur Nekrol des Etudes de l'Asie,' la France Literaire.)

KLEBER, JEAN BAPTISTE, according to the best authorities, was born at Strasbourg in the year 1754, though some place the date of his birth three or four years earlier. He was brought up by his father, who was a domestic in the household of the Cardinal de Rohan, to the profession of an architect, and was sent to Paris at an early age to complete his studies. While there circumstances enabled him to render some important services to two young Bavarians, who, having interested themselves in his behalf, induced him to accompany them to Munich, and through their influence he entered the military corps. His rapid progress in science of war gained him the patronage of General Kaminzig, son of the celebrated Austrian minister of that name, by whom, at the completion of his college career, he was appointed to a confidential agency in an Austrian regiment. He served seven years in that corps, which he left in 1783, in order to return to his native country. He there resumed his former profession, and obtained the situation of inspector of public buildings at Belfort in Upper Alsace.

The breaking out of the French Revolution opened to him a more brilliant career. He had taken a prominent part in a revolt at Belfort in 1791, and had enabled the republicans of that town, by putting himself at their head, successfully to resist the regiment of Royal Louis, which had been called to suppress it. To screen himself from the consequences of this action he enlisted as a private soldier in the grenadier company of the battalion of volunteers which had been raised in the department of the Upper Rhine. By his bravery and talents he soon attained the rank of adjutant-major, in which capacity he acted for some time under General Custine, and when Custine was afterwards brought to trial, he had the courage to present himself before his sanguinary judges, and give testimony in his favour. At the siege of Mayence in 1793 he displayed considerable courage and judgment; his services being thus rewarded by the rank of general, shortly afterwards he became brigadier-general. From thence he was ordered to La Vendée to oppose the insurgent royalists; he led there the soldiers of the garrison of Mayence, on which he was appointed, and probably saved the town from the threatened attack of the French army. At the battle of Tourouj (September 19, 1793), while charging the enemy at the head of the advanced guard of his regiment, he fell with several wounds, and his life was only preserved by the prompt assistance of his soldiers. The agents of the National Convention coerced into a crime his humane interference in stopping the cruelties which were exerted towards the priors held in his canton, and he was forced to make a hurried and dangerous escape to the south of France; but he was finally able to escape to Switzerland. However he was only removed to a command in the Army of the North, and afterwards in that of the Sambre and Meuse, where he rose to the rank of a general of division.

At the battle of Pierre (June 26, 1794) he commanded the left wing of the French army, and by his skilful manœuvres greatly contributed to the victory. He then marched against Mons, which he took from the Austrians, and having advanced to the right bank of the Schelde, forced the enemy back to the right bank of the Rhine. Returning towards Maastricht, he took that strong fortress, after a siege of twenty-eight days. In 1795 he directed the passage across the Rhine of the army of the Sambre and Meuse, and, when compelled to retire before superior forces, he effected a retreat in which his cool intrepidity and skilful dispositions were alike remarkable. In the year following he undertook the glory which attended the success of General Jordan's operations at the opening of the campaign; and he afterwards refused the command of Pichegru's army, when this general was disgraced for bolding treasonable communications with the enemy.

(From a work of A. Quéré.)

Discontented with the manner in which the Directory managed the military affairs, Kleber retired to Paris, where he spent the greater part of the year 1797, and occupied himself with the completion of his works which were left unfinished when he was appointed to the chief command of the army for Egypt. He made it a special request to the Directory to be allowed to take him as one of his generals of division. Kleber joyfully accepted the command, which contained in it all the brilliant achievements already prognosticated his future glory. The army likewise which he accompanied was in a great measure composed of the veteran soldiers who had distinguished themselves in the campaigns of Jordan's operations in Syria; he there distinguished himself by the capture of the forts of El Arish and Gaza, and was at the taking of Jaffa. He was also at the memorable siege of St. John of Acre, where he rendered himself conspicuous by his undaunted bravery, and shared every danger with the common soldiers. He was however withdrawn from the siege by order of Bonaparte, who desired him to march with his division to reinforce the troops stationed at Nazareth under the command of General Brune. In acquiring command of the remnant of the Austrians, including his division, and of the remnants of the Mamelukes under Ibrahim Bey, the Janissaries of Aleppo and Damascus, and numerous hordes of irregular cavalry, who were advancing to the support of their king, the task proved to be a difficult one. This expedition was most opportune, for the enemy had already crossed the Jordan, and were rapidly pressing in considerable numbers towards the coast. Kleber left Nazareth with the entire body of his troops in order to make an attack upon the Turkish camp, but in attempting to do so he was anticipated by the enemy, who advanced against him with fifteen thousand cavalry and as many infantry. Kleber formed his small army of two thousand men in squares, and placed the artillery at the angles, which had scarcely been effected when he was fiercely attacked by the whole force of the enemy's horse. A deadly fire from the close ranks of the squares responded to this impetuous attack, and for six hours that the contest lasted not one square was broken nor a foot of ground lost. Suc- cour at length arrived, and the battle of Mount Thabor (April 17th, 1799) terminated in the total defeat of the Turkish troops. Kleber was wounded in vain, every assault against it proved unsuccessful, and British valor, combined with Asiatic enthusiasm, was finally triumphant. (Ackere, P. C.; Bonsart, F. C.)

The British fleet, under Hawkesworth, gained a signal victory at Abukir another signal victory over the Turks; and the day after this decisive battle Bonaparte returned to Alexandria, where he learnt the capture of Cairo by the Russians and Turks, and that the close of the campaign. For M title the circumstances, combined with the loss of his fleet at the battle of the Nile, determined him upon leaving Egypt.
On the 22nd of August, 1799, he secretly embarked, accompanied by several of his generals, his secretary Bourrienne, with Bertollet and Monge, who had joined the expedition for the furtherance of science. Before leaving he appointed General Kleber to succeed him in the chief command of the Egyptian army, and authorized him to conclude a convention for the evacuation of the country in the event of no succor arrive within a month from the time of his departure. He was sensible that the mortality from the plague among his soldiers should amount to fifteen hundred men.

The sudden departure of Bonaparte spread anxiety and distress among his troops; the reputation of his successor, however, who enjoyed the highest confidence of the army, tended greatly to dissipate their fears. But the talents of Kleber did not at first appear to be equal to the difficult circumstances in which he was placed. He not only permitted himself to be swayed by feelings of indignation at what he deemed the abandonment of the army by its former chief, but he committed the fault, which in his position became a crime, of openly declaring his opinions to his disaffected colleagues in command; he thus caused the seeds of discontent and desire of home, which had been previously sown among the troops, to ripen to a maturity which soon threatened the ruin of the expedition. The attempt to detach from their country, under whose administration many erroneous and exaggerated statements had been published by Foulseculine the army administrator, and presents a most gloomy picture of the state of affairs, to effect the purpose of Kleber's party was frustrated by Napoleon at St. Helena to the Count de Montholon, and is rendered the more valuable on account of the copious comments which accompany it, and which, though written in no friendly spirit, are a sure valuable testimony.

In this letter Kleber complains that his army is reduced to one-half; that it is destitute of the necessary stores and munitions, and that the greatest discontent prevails. He further asserts that the Maneuleus were dispersed but not destroyed, and that the Grand Vizier was marching from Acre to the head of thirty thousand men. Two copies of this letter were sent, one of which was the originals of the English, and was the immediate cause of the expedition under Sir Ralph Abercromby, by which the French were compelled to abandon Egypt. In justice however to Kleber it must be mentioned that his chief fault consisted in trusting too implicitly to the statements which had been given to him by one who, though loaded with favours from Bonaparte, made this ungrateful return to his absent benefactor in order to secure his present interests.

Kleber, under the influence of these dissonant feelings, addressed proposals of accommodation to the Grand Vizier; though at the same time he made vigorous preparations to repulse an attack. His men being numerous increased the necessity of a negotiation. The Grand Vizier with upward of forty thousand men had crossed the desert, and, assisted by some British officers, had captured the fort of El Arish on the 26th of January, 1800, by which it was agreed that the whole of Kleber's army should return to Europe, with its arms and baggage, either on board their own vessels or some furnished by the Turks; that all the fortresses of Egypt, with the exception of Alexandria, Rosetta, and Aboeular, should be surrendered within forty-five days from the time that the convention was ratified; and finally, that the Vizier should pay a sum equivalent to about 120,000l. sterling. The English admiral, Sir Sidney Smith, though not vested with full authority from his government to conclude such a convention, had entered willingly into it, and was honourably proportioned to its terms. The Grand Vizier, however, had already before these events the British government had dispatched orders to Lord Keith, who had the command of the Mediterranean Fleet, to refuse his consent to any treaty in which it was stipulated to enslave any officers of the English navy. Before this letter from Admiral Keith reached Kleber, warning him of his intention to detain any vessel returning to Europe by virtue of a capitulation. The French commander in chief was revolted at the idea of his shore, which now presented to him of retrieving his military character. Danger revived his energies and roused his courage. He immediately ordered the evacuation of the strongholds to be stopped, and prepared to resume hostilities. In one of those animating proclamations so common in modern French warfare, he indignantly declared to his soldiers that victory was the only answer to such insolence, and bade them be ready to defend to the last drop of blood the honor of the empire.
Released from immediate danger, Kleber now began to direct his energies to more pacific labours, and to apply them to the administration of the conquered country. His plan appears to have been to distribute portions of the territory among the veterans of the army, and to accept the conquests followed by the British government in India in enlisting in its service the native troops. Scarcely however had he entered on this work when he became the victim of an assassin. A native of Alexandria, Sulaiman, was invited to the atrocious act by religious fanaticism and the prospect of an ample reward. He had performed the piligimes of Mecca and Medina, and his mind was deeply imbued with the tenets of the Mahometan faith. He chance to be wandering in Palestine, when the retiring remnant of the vizier's army was passing through that country, and he became acquainted with the sultan of the Janizaries, at whose suggestion he consented to become the instrument of what he considered divine vengeance on 'the sultan of the French.' He was furnished with a sum of money, with which he proceeded to Cairo, and sent several weaks in seclusion in a mosque of that city. He had intimated his purpose to the four principal sheikhs of the mosque, who, though they attempted to dissuade him from it, took no steps to prevent its execution. He armed himself with a poison dagger, and followed Kleber several days without being able to effect his purpose, he at length determined upon unconcealing himself in an abandoned cistern in the garden attached to the mansion which the general occupied. On the night of the 20th of May, Kleber was on his way home, accompanied by Proteus, the architect of the army, and he was pointing out to him some repairs which the building required, when Sulaiman presented himself before him as a suppliant for arms; when the architect assented to his request, he seized an opportunity of rapidly striking him several times with his dagger. The architect, who was armed with a stick, attempting to interfere, received a severe though not deadly wound. The premature vigilance of Kleber, the anxiety at the crisis of his illness, and the presence of the assassin, whom they found concealed behind some ruins, Universal sorrow spread through the army, and the Arabs themselves, who had frequently admired and experienced his command, joined in lamenting this unforeseen event. A military commission immediately assembled to try the assassin, who boldly confessed, and even gloried in his crime. The four sheikhs, the partake of his confidence, were beheaded, and Sulaiman was impeached alive.

Thus prematurely perished this distinguished general, and with him the hopes of the eastern expedition. He had formed many important designs for colonizing the country, and it is probable that, under his judicious rule, it might long have preserved a valuable acquisition to the French Republic.

There is no military man, says Napoleon, 'who will deny that the army of Abercromby would have been defeated at 4th of June, if he had not been of the weight of a young fanatic, acting on the faith of a doubtful passage of the Koran, in the general balance of the world.' Though many may hesitate to agree with this assertion, the general reputation of the illustrious commandant of Kleber was very favourably with those of his successor General Manou, to whom by seniority devolved the chief command of the expedition. In a conversation with Dr. O'Meara, Napoleon further remarks, that of all his generals, Desaix and Kleber possessed the greatest talents. There was also a melancholy coincidence in their deaths: on the same day, and nearly at the same hour, that Kleber fell under the stroke of an assassin in Egypt, Napoleon, who had left that country about three months previously, found a glorious death on the plains of Marengo.

'A Kleber,' says a celebrated French writer, 'was the finest man ever born to the literary and intellectual world, whose features were animated by the fire of his soul, his valour at once bold and calm, his prompt and sure intelligence, rendered him on the field of battle the most commanding of commanders. His talents, though unaided by education, were brilliant and original. The works of Flutsch and Quintus Curtius were his constant and exclusive study; he sought in them nurture of lofty minds which the narrowness of his own education had not justified; his mind was capricious, indolent, and capricious. It has been said of him, with truth, that he was as unwilling to command as to obey. He obeyed indeed under General Bonaparte, but it was under duress. His lofty sentiments, his position however, were a filial all the greater, and as such, he was magnificent, indolent, and capricious. It has been said of him, with truth, that he was as unwilling to command as to obey. He obeyed indeed under General Bonaparte, but it was under duress. His lofty sentiments, his position however, were a filial all the greater, and as such, he was magnificent, indolent, and capricious.

While the improvement of refracting telescopes engaged the attention of mathematicians it happened that Dollend, in England, proposed objections to an assumption of Euler, that when light passes from air to glass and from water to the air, the effect of its refraction is proportional to the logarithms of the refractive indices of the media. This hypothesis was entitled 'Testamen de definiendis et corrigendis aberrationibus radiorum luminis sphericis refracti, et de perficiendo telecopio dioptrico,' and published at St. Petersburg in 4to. in 1762.

Newton's experiment on which it was founded, were impugned by Klingsiethenia, who, from his own experiments, found that the light emitted after the refractions was affected with a different colour, under the circumstances which Newton supposed that it would be wholly free from it. In 1754 he transmitted to Dollond an account of his experiments, together with some inquiries relating to the dispersions of heterogeneous light in lenses, and these papers induced that distinguished artist to have again recourse to experiments with a view of discovering more precisely the phenomena of refraction. It was the circumstance afterwards that Dollond discovered that combination of lenses of flint and crown glass by which the dispersions of light have been so nearly corrected in optical instruments. A paper was published, in Latin, an edition of Euclid's 'Elements'; a translation in Swedish of Mushenbrock's 'Physics,' and two discourses, in Swedish, which were delivered before the Academy of Sciences. One of these is an Essay on the mechanical Pothend; and the other relates to some electrical experiments which had been made at that time. He was early made a member of the Royal Society of Upsal; and he was afterwards received in the Academy of Sciences at Stockholm. He was elected a fellow of the Royal Society of London in 1750; and in the 'Philosophical Transactions' for 1751 there is a paper by him on the quadrature of hyperbolas.

Klingenstierna died Oct. 26, 1785; and by order of the queen, the mother of his pupil Gustavus III., he was buried in the tomb of Dalin, who had died a short time before him.

KNAPPIA, a genus of plants belonging to the natural order Gramineae. Its leaves have an inflorescence, with a somewhat one-sided raceme. The flowers solitary; glumes not keeled, and blunt. It has 2 palis, which are very hairy, smooth, oblong, unequal, and without awns. There is but one species of Knappia. K. acriglum is a very small grass, with a slender viscid stem, in fact, in some parts of Europe, it is regarded as a weed. The spikelets, consisting of 5 to 10 closely set sessile spikelets. It is found in sandy calcareous pastures, but is a rare grass.

KNAUTIA (named after Christopher Knaust, a German botanist), a genus of plants belonging to the natural order Dipsacaceae. The inner calyx is cup-shaped, with radiating teeth, the outer one forming a thickened margin to the germen. It has a 4-flod corymb, a fruit with 4 sides and 8 little recesses, the receptacle with spinous scales shorter than the involucres.

Knibb, the Field Scabious, has its lower leaves simple, the stem-leaves pinnatifid, the inner calyx with 8 or 16 somewhat awned teeth. The stem rises from 2 to 3 feet in height, is slightly branched, and with but few leaves. The flowers small, about the size of a pin-head, have no stamens, and it is stated that it is the only British species of this genus. There are a few species of Knautia natives of Europe.

KNIBB, REV. WILLIAM. Of the early life of this devoted missionary, few particulars have yet been made public, but the very brief interval which has elapsed between his unexpected death and the time of writing this article (January, 1846) is sufficient to account for the lack of such biographical information. From a sketch of his life and character in the 'Patriot' newspaper, November 22, 1845, to which we are mainly indebted for the materials of this notice, it would appear that he was born at Kettering in Northamptonshire (a place, it may be remarked, early connected with the history of the Baptist Missionary Society), and that in the year 1838 he undertook the charge of a school connected with one of the Baptist Mission churches in Jamaica, where he died, in May, 1824. The intelligence of his death so excited the zeal of William Wilberforce, and the sympathy of many other liberal friends, that he offered himself to go out to supply the place of his deceased brother; and, his offer being accepted, he sailed, with his wife, in November, 1824. On his arrival he was appointed by the brethren of Kingston to the north-western part of the island, where he took charge of the Ridge Church Mission, a connexion with Savannah-la-Mar; and at the time of the death of Mr. Mann, another missionary of the same denomination, he accepted a pressing invitation to succeed him as pastor of the mission church at Falmouth, and to form a church at the burrington where he died.

A short time prior to Mr. Knibb's settlement at Falmouth he was brought into painful notoriety in consequence of the breaking out of an alarming spirit of insurrection among the slave population. A notion had been excited by the death of some negroes suppressed in the negroes to the effect that the King of England had determined to emancipate them from slavery, and that the free papers, as they termed the supposed announcement, had been sent to the West Indies, but had been suppressed or held back through the influence of the slave-owners; and, in consequence of this belief, the slaves upon several estates in Jamaica avowed, towards the latter end of December, 1831, their determination to do no work after Christmas. So soon as the missionaries became acquainted with this state of things, they endeavoured to remove the erroneous impressions from the minds of such of the negroes as were under their influence, and were so active in their measures as to lead to a report among the disaffected slaves that the white people had bribed Mr. Blyth (a Presbyterian missionary) and Mr. Knibb to withhold their freedoms. Insurrectionary movements were, in spite of all the efforts of the missionaries, actually commenced by the negroes, although the interpolation of Mr. Knibb, who possessed great influence among the slaves through the circumstances of his relations with them, kept them from breaking out into open insurrection. Notwithstanding this fact both he and his brother missionaries were regarded with great jealousy by the planters, overseers, and others in the slave-holding interest, whose enmity had been excited by their efforts for ameliorating the condition of the negroes, and by the part they had taken in exposing many cases of gross cruelty and oppression. On the 1st of January, 1832, Mr. Knibb was compelled, without regard to his sacred office, to bridge on the island, and was arrested and debarred from any communication with his family, upon the plea of alarming intelligence by which it was pretended, the missionaries were implicated in the rebellion. After suffering much persecution, he was released in February, no evidence being obtained to support a criminal prosecution; but in March fresh steps were taken to bring him to trial, though on the day appointed for trial the proceedings were abandoned upon the appearance of about three hundred witnesses who came forward, upon a few hours' notice, in his defence.

During the continuance of disturbances in the island Mr. Knibb's chapel and mission premises at Falmouth were razed to the ground by the men of the St. Ann's regiment; similar outrages, in which he was guilty of no participation in any of the political questions on which it was desirable to observe a rigid neutrality. Mr. Knibb was accordingly cautioned not to commit the Society by his proceedings; but, warned with enthusiasm excited to the highest pitch by his personal knowledge of the horrors of the system, he boldly declared that the Society's missionary stations in Jamaica could no longer exist without the entire and immediate abolition of slavery, and, feeling that the time had arrived for making his determination at the annual meeting of the Society in the 21st of June, to avow this at the risk of his connection with the Society. Mr. Knibb carried the meeting, and subse-
a menace of preventing the evils anticipated from sudden emancipation. He showed that many of the worst features of slavery were continued under the guise of apprenticeship, and insisted on a direct and absolute invalidation of law by immediate emancipation. After the complete emancipation of the slaves or apprentices, on the 1st of August, 1838, Mr. Knibb purchased, by the aid of English friends, a tract of ground for the establishment of an independent community and occupation for the liberated negroes; and he erected a normal school at the village of Kettering, in Tredawney, for training native and other schoolmistresses for both Jamaica and Africa. In 1842, in consequence of the prosperous state of the mission churches in Jamaica, it was determined by the missionaries and congregations to separate themselves from the Baptist Missionary Society, so far as any dependence upon the Society's funds was concerned; and in the same year Mr. Knibb visited England to promote the establishment of a theological seminary in connexion with the native mission to Africa, which had been commenced about two years before, through his exertions. In the early part of 1845 he again visited England, to obtain pecuniary aid for the negroes connected with the Baptist churches in Jamaica, who, in a new way, made the victims of cruel oppression, in consequence of the adoption, by the colonial legislature, of a system of taxation which bore upon the liberated negro labourers with extreme severity, by limiting the supply of food and other necessaries, and at the same time importing, by the increased seizure of their profits, of the number of foreign labourers, so as to overstock the labour-market, and reduce the persecuted negroes to the greatest distress. Having succeeded in obtaining both sympathy and pecuniary assistance, he returned to Jamaica in April, 1846. In the following November he was seized with yellow fever, and died, after an illness of only four days, on the 16th of that month, at the village of Kettering. Though his funeral took place on the following day, there were the regrets entertained for his memory that not less than eight thousand persons are said to have assembled on the occasion.

It is yet, perhaps, too soon to form, between the enthusiastic friends and admirers, and the bitter detractors of his political opponents, and of the men whose oppressions he expressed with such unfeigned courage, an accurate estimate of the character of William Knibb. Of a peculiarly ardent temperament, and feeling that he had undertaken the championship of a cause which demanded all the zeal and energy which could be called into exercise for the exposure of monstrous wrongs, he sometimes exceeded, in the estimation of his best friends, the bounds of prudence, if not of charity; but it should never be forgotten that his long residence in Jamaica, and his intimate knowledge of the state of the negro population, caused him to feel with an intensity not to be surpassed, the position of his friends in this particular, in which he laboured to abolish or to mitigate. As an instrument in the mental and moral elevation of the negro character, the name of Knibb will long be honoured by the friends of the negro race. The full account of all important transactions in which he was involved is given in the second volume of Dr. Cox's 'History of the Baptist Missionary Society.'

KNOLLER, MARTIN VON, a distinguished German painter of the eighteenth century, was born in the village of Steinach in the Tyrol, in 1725. His father appears to have been a poor painter of some sort, and he intended his son to follow his own pursuit. He was however in such circumstances as to make it necessary for his son to perform the menial work of the house, which Martin appears to have found particularly distasteful. The boy accordingly ran away from home, and obtained shelter in the house of a rich man, the Baron von Hornay, at Innbruck, who, when he had heard the boy's story, let his father know of his safety, and placed him with an ordinary painter of the name of Fögel, who thus became Martin's master. He afterwards has thought that the slightest influence upon him, if any at all. Martin's father however required his son's services in every way, and he was forced to return home, where he divided his time between the apprenticeship at art in sand and stone work, and in what other way he could, and in the performance of his father's domestic offices. Such was the state of affairs when circumstances brought the painter Paul Troger, on his return to Vienna from Steinach, where he had found some of the extraordinary productions of Knoeller, then twenty years of age. Troger perceived the lad's ability, and offered to take him with him to Vienna. Young Knoeller went with his patron, and in eight years from that time he had not a superior of his own age in the Austrian dominions. Already, in the years 1748-50, he assisted Troger in the frescoes of the cathedral church of Brizen; and in 1758 he obtained the commission for the frescoes in the chapel of the corporation of the Count Firmian, a nobleman of noble family, who was then ambassador at Naples, where he employed him much in that city, and in the decoration of his palace at Milan. Knoeller visited Rome several times subsequently, and contracted a close friendship with Winckelmann and Mengs. He finished his one of the most important works, the frescoes of the church of Volders near Hall, in the Tyrol, consisting of passages from the life of San Carlo Borromeo. In 1756 he returned to Milan to his former patron, Count Firmian, whose esteem and patronage induced Knoeller to make Milan his head-quarters, and he there married, in 1757, the daughter of a merchant, by whom he had nine children. Knoeller painted many works in Milan, in oil and fresco, the best of which is a ceiling in the palace of the Prince Belgioioso, representing the apotheosis of one of his ancestors. The palace of the Count Firmian was rich in Knoeller's works. His principal German works are the frescoes in the residence of the Count Firmian at Tunbridge Wells, and the seven cupolas of the church of Neresheim in Wurttemberg, painted in 1770-75, for which he received 22,000 florins. He painted a large fresco, 110 feet by 33, in the library of Count Firmian at Milan. He did also at Vienna, and there are altars-pieces by him in several churches in the south of Bavaria. He was much engaged also at Vienna, but chiefly in portrait painting; he was there ennobled, with the title of Prince of the Holy Roman Empire. The are many of his works in the Tyrol, at Innsbruck, Bozen, and other places. The church of his native place, Steinach, possesses three altarpieces by Knoeller. He died in 1804. He was gay in his colouring, and his compositions are of a very correct and serious kind. His figures are characterised for their physical qualities—dramatic and effective composition, strong expression, and vigorous and uncommon attitudes. His sphere was almost exclusively the practical part of art; the true historical and aesthetical he hardly approached; but this might be said of many more eminent painters. A Life of Knoeller was published in the 'Beltrage zur Geschichte und Statistik von Tyrol,' for 1831.
priest nearly forty years with great regularity. In the latter part of his life he resided in London. He was much admired as a preacher, and frequently gave his aid in behalf of public charities by delivering a sermon. He died while on a visit to his son at Tunbridge, Sept. 6, 1821.

Dr. Knox’s chief works were—1. Essays, Moral and Literary, 12mo., 1777, which came out anonymously, and met with so much success that he republished them in 1778, with additional essays, in 3 vols. 12mo.; many editions have since been published. The following is an extract from the Methods of acquiring Useful and Polite Learning, 8vo., 1781, enlarged in 1785 to 3 vols. 8vo.

This work was chiefly intended to point out the defects of the system of education in the English universities and public schools. It had some effect in producing a reformation, 8vo.; 'Elegant Exports in Prose,' 8vo., 1782. 'Winter Evenings, or Lectures on Life and Letters,' 3 vols., 12mo., 1785. 8vo., 'Elegant Extracts in Verse,' 1790, 8vo. 6. Sermons intended to promote Faith, Hope, and Charity,' 1792, 8vo. 7. 'Elegant Epistles,' 8vo., 1792. 8. 'Family Lectures,' 8vo., 1794. 9. 'Christian Philosopher, or an Attempt to Display the Evidence and Excellence of Revealed Religion,' 2 vols. 12mo., 1795. 10. 'Considerations on the Nature and Efficacy of the Lord’s Supper,' 12mo., 1795. Dr. Knox published a few other minor works, occasional writings.

Dr. Knox’s writings were once much admired. His style has considerable neatness and elegance, but he has little originality or power of thought, and his popularity has for some years chiefly depended on his sermons. The 'Elegant Extracts' were made with much taste and judgment. They were very useful works in their day, and had for many years a large circulation.

(Knox, Theological and Literary, 1822; Watt’s Bibliotheca Britannica.)

KOBEI, the name of several German and Dutch landscape painters, of whom the following are the most distinguished.

Ferdinand Kobell was born at Mannheim in 1740, and was educated by his father with a view to his obtaining an honourable position in the civil service of the Electoral government. He then entered the hofkantoin, or counsel of the exchequer. Ferdinand however had an invincible passion for landscape painting, which the encouragement of the elector palatine, Karl Theodor, enabled him finally to follow, notwithstanding the opposition of his father. He studied eighteen months at Paris, in 1768-70, at the expense of the elector, who appointed him his cabinet painter after his return to Mannheim: he was also made a member of and secretary to the Academy of Mannheim. In 1793 he removed to Munich, where he died in 1799. Kobell was also a very able etcher: a set of his prints, 179 in number, was published in Nürnberg in 1769.——'Oeuvre complete du peintre. Dessins de Kobell &c.' — 'Kobell: His Works.'—'Catalogue Raisonné' was published by Baron von Stengel, in which 207 prints are described. Nagler has printed a list of Kobell’s works, but they are not all selected, true in colouring, and executed with care: the figures in them are painted by himself.

Franz Kobell, the younger brother of Ferdinand, was born at Mannheim in 1749. He was intended for a merchant, and spent four years in a merchant’s house at Mainz; but his love for the arts, especially landscape and architecture, finally overcame all obstacles, and his brother’s patron, the elector Karl Theodor, befriended him also, and enabled him, in 1776, to visit Italy, where he remained an enthusiastic student of Italian scenery, chiefly at Rome, for nine years. Franz Kobell, though he did not make many pictures, either of oil or water-colour, has scarcely a painter sally, for his works are almost exclusively drawings, chiefly with the pen, and tinted with sepia. He was so industrious in this style of art, that the number of his etchings, which are remarkable for good taste, is not insensible. The greatest bulk of which are in three collections—that of the Duke Albert of Sachsen-Teschen in Vienna, that of H. von Rigal in Paris, and that of Baron Stengel in Munich. He died at Munich in 1797, to the crook of whose elbow he left "Kunstblatt" of the same year, from the pen of his friend Spohr, the author of an excellent work on Italian art of the earlier ages—'Die Kunst in Italien,' 3 vols. 8vo., Munich, 1813. (Mosel, Miscellanea Artistici Inferi; Lipowsky, Künstler-Lexicon; Nagler, Künstler-Lexicon.)

KOBRESIA, a genus of plants belonging to the order Cyperaceae. It has the spikelets aggregate; the lower flower pistilliferous, the perigone of one scale inclosing the germen and covered by the glumes. The upper flower staminiferous without any perianth. There is but one species of this genus, K. curvata, which has an erect stem from 6 to 12 inches in height, slender leaves about two-thirds the length of the stem, and six to eight flowers. There is often an abortive stamens at the base of the nut. This plant is found throughout Europe and in Great Britain, on moor land, in Yorkshire, cornfields, fields of Perd hair.

(Babington’s Manual of British Botany.)

KOCHEL, JOSEPH ANTON, a celebrated German landscape painter, was born of poor parents at Obereibheim, near Mainz, in the first year of the Leuchtenberg dynasty of Brandenburg in 1788. Some of his early attempts attracted the notice of Bishop Umughler, vicar-general of Augeburg, who placed Koch with a painter in that city and provided for his maintenance. He was shortly afterwards sent by the bishop to the Carl-Academie at Stuttgart, where he remained seven years, and became in the meantime an able landscape painter. Koch tried his fortune in Rome at an early date, and was met with complete success; he married a Roman girl and settled himself fixedly in Rome, where he enjoyed a great reputation for, with the exception of a short interval, at least half a century, and he was for years considered the German artists. He died at Rome, January 12, 1839.

Koch was not exclusively a landscape painter, though he is chiefly distinguished as such. He is known for some clever historical scenes, and is celebrated for his landscapes. The works of Koch are, Noah’s Sacrifice, the Emancipation of the Tyrol by Hofer, the Flight of Laban, the fresco illustrations to Dante in the Villa Massimi, besides some others. He has painted several works for the Berliners, and also a rather characteristic pictures of a peculiar class of scenery than prospects of particular localities. He frequently composed his landscapes out of such peculiarities of mountain scenery as were mingled with his individual taste, but the parts were always well arranged, and true and characteristic in their details. In colouring he was not excellent, but rather heavy and monotous. His latest works were comparatively few. Koch, although a talented and finished artist, had an admirable skill, and among his works in this class are 24 designs from the anciantable of the Arcagonic expedition, after Carstena. (Nagler, Neues Allgemeines Künstler-Lexicon.)

KOELERIA, a genus of plants belonging to the natural order Gramineae. It has unequal glumes, the upper one with 2 or 3 ribs, shorter than the spikelets, which is compressed. The outer scales is narrowed, keeled, and acuminate; the seed loose, and the styles terminal. There is but one British species of this genus.

K. eripinnata has a compact panicle, spicate, oval, and interrupted distichous spikelet, pale. Scribed and acute; the leaves narrow, rough at the edges, and ciliated. In dry places the leaves are much shorter than the stem; in damper places elongated, and often nearly as long as the stem.

(Babington, Manual of British Botany.)

KONIGA, a genus of plants belonging to the natural order Cruciferae. It has an oval compressed poutch, from 1 to 3 seeds in each call, simple filaments, and 8 hypogynous glands. But one British species of this genus has been discovered, K. maritima, which is a procumbent plant, with bipartite leaves, linear lanceolate aculeate leaves, oval pointed glabrous pod. It is the Laboratory of Koch, and the Gylcy of Lindley. The flowers are white and sweet-scented.

(Babington, Manual of British Botany.)

KOTTBUS, COTTUS, F. C.

KRAFT, A. G., was an old sculptor and architect of Nürnberg, where he was born about 1450; he married in 1470. There are several of his performances still extant in the city and churches of Nürnberg, but the principal is the monuement of Luyken, erected 1514—1515. in the church of St. Lawrence, Worms. In it is the in the form of a square open Gothic spire, and is 64 feet high, the pinnacle being turned downwards, like a capital. On the south side is the gilded crown of the choir. The choir is placed immediately upon a low platform which is supported partly by the kneeling figures of Adam Kraft and his two assistants; the rail or baluster of gold, and the platform in the right is adorned, and the figures of eight saints. The whole tabernacle is also profusely ornamented with small figures in the round and bas-relief:—immediately above the choir. On three sides, are represe-
Academy, it succession Petersburg, above very changed an work. He and his service and return with him to Petersburg, but Kupetzky was obstinately fond of his liberty, and would never enter the service of any prince. The great Peter gave him a commission to return in his own service. All that Kupetzky had ever required of the Emperor of Austria was, that he might be allowed to worship God in his own way. He had been beard to the Bohemian Brothers. This liberty, however, very nearly involved him in serious difficulties, as he was accused or threatened to be accused, by some of his rivals, of malignant heresy; and only his great fortune, and the intervention of the Empress, and his secretly left Vienna and settled in Nurnberg, where he died in 1740. Kupetzky painted history and portrait, but chiefly portrait. His pictures have a great deal of character and much effect: his friends and admirers says they combine the vigour of Rubens, the truth and elevation of Vandyke, and the effect of Rembrandt. Many of his portraits and some of his pictures have been engraved, especially by Bernhard Vogel; in mezzotint engraved by Vogel were added to V. D. Preissler and published in a collection in folio at Nurnberg in 1745, under the following title:—Joannis Kupetzky, incomparabilis artificis, imaginum, et tituli specimen, a quo aliquis quindecim decadas arte quam vacant nara crici iaceat, a Bernhardo Vogelo, jam vero similiter continuata opera et sumptibus Valentinis Daniellis Preissleri, Chalcographi. Kupetzky is a poet of himself, in the pursuit of his art, the work of a prolific merit, has been copied by L. de Laborde, from Vogel's print, and is inserted as a specimen in his history of mezzotint engravings.—Histore de la Grave en Maniere Noire.' J. C. Fussli published a Life of Kupetzky, with one of Rugendas, at Zurich, in 1758. (Florilo, Geschichte der Zeichnenden Künstler, &c.; Dlabac, Allgemeines historisches Künstler-Lexicon für Böhmen.) KUDEDISTAN (the country of the Turco-Turkis) comprehends the larger portion of that mountain-region which divides the elevated table-land of Iran (Persia) from the low plains of Mesopotamia or Al-Jezireh. As it does not constitute a political division, its boundaries are not exactly determined. Some authors consider the country surrounding the lake of Van as forming a part of Kurdistan, but as that country is mostly inhabited by Armenians, and there are only a few Kurds among them, the mountain-range of the Ererd Tagh (39° 20' N. lat.) must be considered as constituting the boundary-line between Armenia and Kurdistan. From this range it extends in a south-eastern direction to the province ofomerata, and from thence to the equator of the middle planet; the remainder belongs to Persia, and constitutes the province of Kurdistan, of which Kermanshah is the capital. The higher mountain-region occupies the northern portion, and extends from the Ererd Tagh to the Ererd-Mansur, which, as it west approaches the banks of the Tigris south of Jezireh-im Omar; from which point it extends in an east by south direction across the whole region, being overtopped near the boundary-line of Persia by the elevated peak of Rondaws (10,120 feet above the sea-level). This range is called at its western extremity, where it hardly rises a thousand feet above the sea-level, the Soli Range, but in the middle, where it attains 8000 feet and more, the El Kiar Mountains; it is still higher where it approaches the table-land of Iran. The whole country between this range and the Ererd Tagh is mountainous. In the vicinity of its northern limits the rocky masses are rarely and not deeply furrowed by depressions in the shape of valleys. They form a table-land, from 6000 to 7000 feet elevated above the sea-level, whose surface presents a succession of low hills with gentle declivities and small plains between them. This is the table-land of All Bagh, on which very lofty summits rise. The climate is dry and very arid, and the vegetation scanty. It is mostly used as pasture-ground in summer. In proceeding southward the country gradually rises, and the soil of the Ererd Tagh is especially fit for the raising of grain; but the masses between them rise higher, and thus the table-land is changed into a mountainous country consisting of high ridges with steep declivities and comparatively narrow valleys between them. Some of the ridges attain a great elevation,
as the Marannan mountains, the Jawr Tagh, and the Jelooch range, in the lower half of the basin, and rise between 12,000 and 15,000 feet above the sea. The de-
clivity of the ridges and the valleys present a vigorous ve-
etation in the numerous forests and in the growth of the dif-
ferent species of plants that are indigenous in this region.

The forests chiefly consist of different kinds of oak (Quercus
valonia and Q. infectoria), from which those immense quan-
tities of gall-nuts are collected which constitute the most
important product of the district. In winter the
European cereals are raised; and the orchards produce
apples, pears, plums, and cherries. Many of the valleys open
towards the plain of Mesopotamia, and these are wider, but
the banks are more cultivated, and on the south contain
more than two miles wide, and generally not half so much.

This portion of Kurdistan is in possession of some tribes of
Kurds, which are independent when the pashas of Bag-
dad and Mosul are not in arms to punish the least act of
disobedience. It is as difficult for the Turks to penetrate
into the valleys of these regions as for the Russians to get
possession of those of Circassia. Probably more than half the
population is Mohammedans, and the other half Christians,
among whom the Nestorians are the most numerous. Their
patriarch resides in Julner, a small town situated in the
valley of the river Zab Ala, or Great Zab, and enjoys almost
the same kind of independence. Its government is divided
into the towns of Amadiyah and Rowandiz, the two
places whence the gall-nuts are exported. Amadiyah lies in
a valley from five to six miles wide and very fertile, and is
hailed by the Kurds as a more fertile soil than that of 90 feet
above the valley; it contains about 200 houses, many of which
are inhabited by Jews. The town of Rowandiz is some miles
west of the peak of Rowandiz. It is built on a tongue of land
formed by the confluence of two rivers, and contains more
than 1000 houses and perhaps 10,000 inhabitants. Numerous
caravans pass between this place and Mosul. They export
gall-nuts, madder, hides, and tobacco, and bring back several
European articles.

The southern portion of Kurdistan, or that which lies
between 36° and 34° N. lat., can hardly be called mountainous,
except in its eastern districts, which are contiguous to the
central ranges of Turkey. The surface however is greatly
diversified by several ranges of hills. Three such ranges may
be traced between the banks of the Tigris and the eastern
mountains. These three ranges go by the names of the Hamrin
Hills, the most south-western, All Tagh, the central ridge, and
Kara Tagh, the north-eastern. They run parallel to one
another from north-west to south-east. The Hamrin Hills
terrain on the banks of the Tigris between the town of
Tekir and the mouth of the Zab Asaf or Lacs Zab (near 35°
N. lat.); the All Tagh, south of the confluence of the
Zab Ala or Great Zab (near 36° N. lat.); and the Kara
Tagh joins the El Kbaar mountains south-west of the peak of
Ramur. It contains some forty to fifty miles, and is divided
into several places by hilly tracts. It appears however that the
greatest part of this region is occupied by plains of considerable
extent. The hills as well as the greater part of these plains are
covered with a variety of crops, mostly quinques. But along the base of the hills, partly on their declivities and
partly in the adjacent level country, there are lands of consid-
erable fertility, well cultivated, and populous. The moun-
tain-region which borders this country on the east varies from
ten to twenty miles in width, and it contains several high ranges,
as the Shabin mountains, the Azmir Tagh, and the Kurkur
Tagh. In the second month of the Persian calendar, the
largest river of Kurdistan is the Zab Asaf, or Great Zab.
It rises in the north-western corner of the table-land of
Ararat, and in a picturesque valley in the vicinity of
Batamuk, and joins the Tigris about 30 miles below Mosul.
At the place of its confluence the rivers are nearly equal in
distance. The waters of the Tigris are highest in April and May, but in July the stream is reduced to one-third of the
amount which it possessed in April. The Zab Asaf is the
largest river of Kurdistan, which, by its affluents, drains the
first-mentioned country, they fall into the Tigris; but they
break through all the lower ridges of Southern Kurdistan.

There are several considerable towns in Southern Kur-
distan. The most important is the chief town of Tigris, for
between the Great and Lesser Zab, in a plain which has a
very fertile soil, yielding rich crops without being irrigated.
The town is built on some considerable hills, which all
traversed by the river. It contains more than 2000 houses;
large mosques, and two baths. Altun Kupri, on the banks of
the Lesser Zab, contains 8000 inhabitants. Kerkuk, farther
south, is a rather large place, which contains on a considerable
commerce with Sulaimaniyah, to which place it sends large
quantities of gall-nuts, honey, sheep, and cattle, brought from
the mountain-region lying farther east, and whence it receives
European, Persian, and Indian goods. Its population may
amount to between 10,000 and 12,000 individuals. There
are some manufactures of coarse calicoes.

Suleimaniyah, the modern capital of Southern Kurdistan,
and the residence of the hereditary pasha or wali, who how-
ever is dependent on the pasha of Baghdad. It is situated
on the base of the Azmik range, and of the peak called Pir
Omar Gudrun, which rises to more than 10,000 feet above the
sea-level. The plain of Bania, at the eastern border of
Sulaimaniyah, is 30 to 40 miles in breadth, and was early
occupied. It was built in 1785, and contains more than 2000 houses
and about 10,000 inhabitants, six caravanserais, five huts, and
five mosques. The commerce with the adjacent country is con-
siderable, and is conducted in this place.

Little is known of the climate of Kurdistan, except that of
Sulaimaniyah, where the winters are very cold and the sum-
mers very hot. Snow covers the plain of Banna for six
weeks, or even two or three months. In the winter the climate is
very agreeable, the thermometer standing at six o'clock in the
morning at 65°; at half-past one, at 78°; and at ten o'clock
in the evening at 65°, but in July the heat is very oppressive,
especially during the northern-winds which are called
sherki, and which affect the human body more than the
samour at Bagdad, as they suddenly raise the temperature
ten degrees and more, and produce the most unpleasant
feeling. They continue to blow sometimes for eight or
ten days, and return frequently, even as late as the end of
September. When the sherki does not blow, the changes of the
atmosphere are very regular in summer. At sun-rise it is quite
calm; but immediately afterwards a light breeze begins from
the east, which increases gradually until the sun attains the
meridian, when it blows a gale, or at least strong
gusts of wind, from the south. Later in the day it
turns to the west, and is considerably cooler.
The mornings are gene-
rally unpleasant, but the afternoons are very
agreeable.

The fields of Kurdistan produce wheat, barley, and Indian
corn; millet and rice are also grown on the borders of the
rivers. The orchards yield figs, pomegranates, olives, oranges,
peaches, plums, apples, pears, cherries, and abundance of
grapes of good quality; in some places there are plantations
of dates. Poplar and chinsh trees (plantanus orientalis) are
planted, and among the forest trees are several kinds of
oak, and also wild pear-trees of great size, and between them
wild rose-bushes.

Sheep, cattle, and horses abound; the best horses are in-
ported from Badgad. There are bears, wild hogs, wild
goats, antelopes, and jackals. Land-turtles are frequent, but
of small size. Bees are very abundant, and honey is a com-
mon manufacture, both in the mountainous and a valley part
of the country; birds are not numerous, except par-
tridges and quails.

Minerals appear to be scarce, except building-stone. In
the mountain-region iron and sulphur are met with; and in
some places these mines are worked on a small scale. There
are several salt springs in the hills between the lesser Zab and
the Diyahlah, from which large quantities of salt may be
obtained. Naphtha and petroleum are also found in some places in
the vicinity of Kerkuk, and some of the springs yield a considerable
revenue to the walls; they are noticed by Strabo (p. 738, ed. Cas.).

Vol. II.-3
As the passes through the ranges of mountains and hills are rather difficult, single travellers are subject to be robbed and murdered. Commerce is therefore carried on by caravans. At least one caravan departs every month from Sulaimaniyah for the Persian towns of Tabriz and Hamadan. They take to Tabriz chiefly goods obtained from Bagdad, as coffee, dates, and European and Indian manufactures; and bring back luxuriant productions for the manufactures of Bagdad, and some silk stuffs. The exports to Hamadan consist partly of goods obtained from Bagdad, and partly of the produce of the country, as tobacco, fruits, honey, ginnel, or ginsel, silk, and manufactures of Kashan, as velvets, brocades, cotton goods, &c. The commerce with Kerkuk, which is the chief market for the produce of Kurdistan, is very active; from that place are brought to Sulaimaniyah ginnel-stuffs, honey, sheep-skins, and cattle; and exchanged for fruits, rice, leather, coffee, cotton stuffs, &c. There is also much commerce with Bagdad, where coffee, dates, and European and Indus goods are obtained in exchange for the silk brought from Tabriz, and for the produce of the country, consisting of sheep, ginnel-stuffs, sumach, cheese, hutter, gambi, towel, soap, and tobacco. These articles are also taken to Media, where they are exchanged for cucumbers and other cotton stuffs, silks of Damascus and Darbehk, stuffs for turbans, boots, and shoes. The least active branch of the commerce of Sulaimaniyah is that with Erzerum, to which place hardly anything is exported except those articles which are imported from Bagdad, for which the returns are iron, copper, and mules. Armenia supplies the whole of Kurdistan and some neighbouring countries with those animals.

The population of Turkish Kurdistan is estimated at about one million, of which four-fifths are Kurds, and the remainder Armenians, Persians, Jews, and Turks. The Kurdish population of Persian Kurdistan may amount to 20,000 individuals. But as a numerous colony of Kurds is found in Kiziloman, and several tribes have also been dispersed over the hilly region in Mesopotamia, and as far west as Aleppo and the Taurus mountains, the whole population of the nation may perhaps not fall short of two millions. The Kurds are a stout race of men, of dark complexion, with black hair, a large mouth, small eyes, and a savage look. They are very regularly built, and attain a great age. Their language is derived from the same stock as that of the modern Persian, but not having been fixed by writing, it has degenerated much more. There are several dialects, which vary considerably in proportion to the distance at which the different tribes live from one another. The name of Kurd signifies a valiant warrior, and is therefore adopted as an honourable denomination. In Turkish Kurdistan the nation is composed of two castes, the warriors, called Belebek or Balans, and the working people or agriculturists, called Gurun. The latter are considered by the Belebek as a race of men totally different from them, and are treated as slaves. The Belebehs are very partial to the ground, and generally are never away from their soldiers. A great portion of the population is still addicted to a migratory life. Even when settled in villages, they leave them in summer, and retire with their herds to the adjacent mountain-ranges, from which they return when the harvest time approaches. Though the Kurds are as good Mohammedi as their neighbours, their women enjoy much a greater degree of liberty, and are frequently met with in the streets. Ladies of rank wear a veil, but the women of the middling and lower classes go out without. The Kurds are much more inclined to associate than their neighbours the Persians or Turks.

The Kurds were known to the ancients. Xenophon (Anabasis, iii. 5, 15, &c.) called them Carduchi (Kapidegas), and later historians Kapidegas, Kapiadas, Gordian. When subject to the kings of ancient Persia, they belonged partly to the province of Assyria, and partly to Media, as at present their country is divided between Turkey and Persia. The battle of Guagamela (Arbela) was fought in Kurdistan, near the modern town of Arbil. After the time of Alexander their country was annexed to the kingdom of Susa, and dismembered from it in the third century before Christ by the Parthians. It afterwards became a part of the new Persian empire, and fell with it under the dominion of the caliphs of Baghdad, and was afterwards especially of the Caliphs of Marid particular to the numerous revolutions in Persia and Mesopotamia. The famous sultan Saladin was a Kurd, of the tribe of Roweandoon, and appears to have possessed at least a part of a country. But it soon passed under the dominion of the Moguls (1258), and finally (1858) was conquered by Timur. After the establishment of the Sfootine dynasty (1652), Kurdistan constituted a part of Persia, and remained so till the seventeenth century, when the Kurds, oppressed by the Persians, revolted, and subjected themselves to the dominion of the Turkish emperor.

KYD, THOMAS, was one of those dramatic poets who immediately preceded Shakspere. Three plays of his are extant—'

LABEO, QUINTUS ANTIUS, a Roman of some distinction, who was the father of an illustrious son. He was at the battle of Philippi, on the side of M. Brutus and Cassius, and after the defeat he killed himself in his tent, and was buried there. (Appian, Civil Wars, iv. 158.) He was a man of great learning, as C. Tacitus testifies; but contrary to the practice of that time, instead of devoting himself exclusively to one master, he attended several. He lived in the time of Augustus. Labeo was distinguished for his knowledge of Roman law and Roman usages, and also for the freedom with which he expressed his opinions to Augustus (Suetonius, Octavius Caesar, c. 54), to whose measures he set himself in opposition. Some critics suppose that he is alluded to by Horace (1 Sat. 3. 82); but there might be other persons of the name of Labeo. Aetius Capito, his rival in legal knowledge, was raised to the consulship by Augustus in order that he might have that superiority in rank which his talents alone could not give him. Labeo never enjoyed any higher honour than the prætorship. (Tacitus, Annal. iii. 78.)

The character of Labeo is given by Gallus (xiii. 10): "Labeo Antius principally applied himself to the study of the civil law, and publicly gave his opinions to those who consulted him. He was also not unacquainted with other liberal pursuits, and he deeply studied grammar, dialectic, and antient learning; he was also well acquainted with other things which are considered of less worth. He cultivated and availed himself of that kind of knowledge especially to clear up most legal difficulties." He was confident in his abilities and acquirements, and bold enough to advance many new opinions. He was a man of courage, and it was said to have produced four hundred different treatises, from which there are sixty-three excerpts in the Digest, and he is very often cited by the other jurists. Labeo wrote commentaries on the Twelve Tables, and on the laws of the Curtius, and written De Disciplina Etrusca. His works which are mentioned in the Digest are, eight books of Institutes, of which Paulus made an epitome with notes; and ten books of Posteriora, so called from having been published after his death, of which Juvencus made an epitome; but Gallus refers to the fourth book of Posteriora. He also wrote Libri ad Edictum, Libri Prætoris Urbanis, and three Libri Prætoris Peregrini.

A brief notice of C. Aetius Capito may be appropriately introduced here, for he was the rival of Labeo, and founded a sect or school which was opposed to that of Labeo. The father of Capito attained the rank of prætor; his grandfather was a centurion who served under L. Cornelius Sulla. Capito was made Consul Suffectus by Augustus a.v.C. 758, and it was during his term of office that he decided that a patron and client had to take his freedwoman to wife against her consent, a decision perfectly consistent with Roman principle. Capito was a flatterer; Labeo was an independent man and said what he thought. Instances of Capito's adulation are recorded by Tacitus (Annal. iii. 70) and Suetonius. He died in the time of Tiberius, a.d. 52. (Annal. iii. 75.)

Capito is often cited by other jurists, Proculus, Juvenculus, Paulus, and once by Labeo: they all call him Ateles. Capito's reputation as a lawyer was very great. He wrote on Pontificial Law at least five books, as appears from Gallus (iv. 6), and numerous books of Conjectures (Gallus, xx. 2; xiv. 7). He also wrote a single book De Officio Senatorii, from which Gallus gives an extract (iv. 10), and a book De Jure Sacrificiorum (Macrobius, Saturn. iii. 10). Gallus (xiii. 12) also quotes a letter of Capito, in which he speaks highly of Labeo's legal knowledge. There are no excerpts from Capito in the Digest.

From the time of Labeo and Capito we date the formation of two opposed sects or schools of law among the Romans. The nature of this opposition is collected from the words of Proculus. (L. 82.) In each of the sects of greater acquirements than Capito and of a bolder temper. He applied to his legal studies the stores of knowledge that were open to him, and thus was led to many new views. Capito shewn to be in this way a more considerable orator than his pupils of the opposite sect; he was one of those who appealed to authority. So far as concerns general principles, we cannot condemn the method of either of these great jurists. Each has its merit, but either of them, if carried too far, may be injurious to jurisprudence. He who handles the matters of law in an enlarged and comprehensive manner, improves jurisprudence, as it were; but he who does not well know what the law is, and if he is more eager to change what is established than to maintain its stability, he may destroy the edifice on which he is labouring. He who merely studies as they do, and is satisfied if he can find authority for anything, however inconsistent with fair dealing and the general interests of society, may be a good lawyer of a kind, but he is a bad citizen. The Roman jurisconsults were mainly engaged in writing on law and giving their opinions (response) to all persons who consulted them. Their business was not that of the modern advocate, who has to make the best of his client's case. The opposition then between Labeo and Capito, between him whose method, if judiciously practised, would lead to a progressive improvement of law, and him whose method would stop all such improvement, if strictly adhered to, hardly constitutes a ground of like comparison between lawyers in this country. Numerous questions divided the respective followers of Labeo and Capito; but it is not always easy to discover in the questions, so far as we know them, sufficient to enable us to trace the two opposing principles of the founders of the schools to their just consequences. Much has been written on this matter; and a great deal has been said for which there is little or no evidence.

The followers of Labeo were called Proculiani, from Proculus, one of the successors of Labeo. Those who attached themselves to the school of Capito were called Sabiniiani, or sometimes Schola Cassiana, from Massarius Sabinius and C. Cassius Longinus. For further remarks on the subject of the two schools the reader may consult Puchtia, Carusa der Inst., i. 98.

LABIATÆ. (Lamelle, P. C.)

LABIDUS, (Matulides, P. C.)

LAPHTHINODYNUM, or Ponticush, an evergreen shrub or tree from the new red-sandstone stra. (Owen) (Salamandrioides, P. C.)

LACE-BARK-TREE. (Daphne, P. C.)

LACTICUM. (Lotus, P. C.)

LACTUCA, a genus of plants belonging to the natural order Composite, the suborder Liguliflorae, the tribe Cichorieae, and the subtribe Lactuceae of De Candolle. It has a cylindrical involucre with the scales membranous at the margin and few-flowered; the receptacle naked; the achenium compressed, wingless, with a long filiform beak, the pappus hair-like in several rows.

L. roeras, Acrid L. has leaves with a prickly keel, horizontal, oblong, serrulate and clasping, maroon, dentate or sinuate, the back white, equalling the fruit, which is black. This plant is found on hedges, old walls, and the skirts of fields through the greater part of Europe, and in milky juice, which when procured and dried it has the name Lactuca Scorzonera. (Lactuca Scorzonera. P. C.) This substance is also procured from the garden lettuce (L. sativa), and in the London Pharmacopoeia the L. sativa is the only plant recognized for supplying this substance. Dr. Christian remarks, the London College however, and many cultivators, are wrong in restricting themselves to the garden lettuce, for the preparation of lactucarium. From information communicated to me several years ago by Mr. Duncan, chemist and druggist in this city (Edinburgh), who has often made lactuca on a large scale, it appears that the Lactuca Scorzonera yields a much larger quantity, and that the produce is of a superior quality. Nor is there any reason for deeming the narcotic properties of the wild lettuce, the scientific name of which has given rise to an exaggerated notion of its activity. The results obtained by Mr. Duncan have been since confirmed by those of Schultz in Germany; who found that a single plant of the garden lettuce yields only 17 grains of lactucarium on an average, while a plant of wild lettuce yields no less than 65 grains. — Mr. Duncan has been enabled to procure the same with the milking of the juice increases till the very close of the time of flowering, namely in the wild-lettuce till the month of October in this climate, the value of the lactucarium is determined by the proportion of the period of the time of flowering. It consequently while the juice becomes thicker a material decrease takes place in the proportion of bitter extract contained in it. For an account of Lactuca sativa and its use as a salad, see
Lettuce. This plant appears to have been cultivated amongst the Greeks, and also used in medicine. It is the *Lactuca* of Dioscorides, ii. 165, also of Theophrastus. Several varieties of the garden-lettuce were used both among the Greeks and Romans as salads.

*L. scariola.* Prickly Lettuce, has the leaves with a prickly keel, pale yellow, short-stalked, and clothed from the summit, the white base, equaling the pale fruit. It is found plentifully in waste places in many parts of Europe, but is a rare plant in Great Britain. It has a stem from 2 to 5 feet high, and panicles. Its juice is not so acid as that of *L. eruca*, but possesses the same properties. It is found on the higher hills of Greece, and is probably the *Lactuca* of Dioscorides. The *Lactuca* of Theophrastus, L., and of Galen, l. ii., according to Fras is the *Lactuca* of Schulz.

There are two other British species of lettuce: *L. salignus*, with a white elongated leaf, twice as long as the fruit, the upper leaves entire, acuminate, and *L. scariola*, with the leaf much shorter than the fruit. [On the Cultivation of the Lettuce, see LETTUCE, F. C.]

(Babington, Manual of British Botany; Fras, Synopsis Plantarum Flora Classica; Christian, Dispensatory.)

LADING, BILL OF. [BILL OF LADING, P. C.]

LAGENAR'IA (from 'lagen,' a bottle), a genus of plants belonging to the natural order Cucurbitaceae. The flowers and fruits have the usual characteristics of the order, and are solitary, with subulate segments shorter than the tube. The corolla is white, with obtuse petals spreading below the edge of the calyx. It has five triangular stamens, the fifth one distinct; three sub陆续, oblong compressed seeds tumid at the margin, 2-lobed at the apex.

*L. vulgaris,* common Bottle-Gourd, is a mucous-scented plant, and clothed with a soft down. It has a climbing stem with tendrils, by which it clings to the objects with its leaves. In its wild state the fruit is poisonous, and Dr. Boyle states that a very intelligent native doctor informed him that cases of poisoning have occurred from eating the bitter pulp in the district where it grows. Some sailors also are said to have died from drinking beer that had been standing in a flask made from one of those gourds. These injurious effects seem however to be removed by cooking, for Don says that the poor people among the Arabsians eat it boiled with vinegar, or fill the shells with rice and meat, and so make a kind of pudding of it. The pulp of the fruit is often employed in pâtés: it is bitter and purgative, and may be used instead of colocynth. This species grows wild in Egypt, Abyssinia and Arabia, where it is called Charrah; it thrives wherever the mountains are covered with a fit soil. There are three other species enumerated by Don growing in Guinea and the East Indies.

In India it is in great veneration by the Hindus in their religious ceremonies.

(Don, Gardener's Dictionary; Lindley, Flora Medica.)

LAGETTA. [DAPPEX, P. C.]

LAGURUS (from *Lyc'us,* a hare, and *eped,* a tail), a genus of plants belonging to the natural order Gramineae. It has a spiked lanceolate flowered, scarious glumes ending in a long fringed seta. The outer pale enlonged in two long setae and with a dorsal geniculately twisted base.

*L. oovata* is the only species, and has a stem from four to twelve inches in height. The leaves are broad and lanceolate, the spikes ovate and subscapes. It is found in sandy places in Germany and on the Continent of Europe.

(Babington, Manual of British Botany; Koch, Flora Germanica.)

LAING, MALCOLM, an historian, was born in Orkney, where he possessed a small patrimonial estate, in 1762. He received the rudiments of education at Kirkwall, and afterwards studied at Edinburgh, where he was one of the most active members of the 'Speculative Society,' an association in which he was joined even after he had produced a book. He was admitted at the age of nineteen to the degree of a master of arts, and in the following year was made a doctor of philosophy. He was a fellow of the Royal Society, and president of the Physico-Medical Society of Baile, to whose 'Acts' he afterwards contributed several memoirs on mathematical and physical subjects.

In 1758 Lambert accompanied two of the sons of M. de Salis to the University of Göttingen; and, proceeding from thence to Holland and France, he returned in 1758 to Coire. At Paris he had an opportunity of conversing with some of the celebrated men of the age, particularly D'Alembert and
LAM \[157\]

Masmier; by the former of whom he was afterwards recommended to the King of Prussia, Frederick III. He quitted the family of Count Sali in 1769, and, having been chosen a member of the Electoral Academy of Bavaria, he went to reside there. In 1772, he was made a member of the Commission of setting the boundaries between the territories of the Valais and the duchy of Milan; and in the following year, in consequence of an invitation from the King of France, he removed to France and spent the remainder of his life. He was elected a member of the Berlin Academy of Sciences, to whose 'Mémoires' he made many valuable contributions; and he was also appointed Chief Superintendant of a commission of superintending the improvements of the kingdom.

While in Holland, Lambert published, at the Hague, a treat, entitled 'Les Propriétés de la Route de la Lumière,' 8vo. (1765), in which he examines the path of a ray of light refracted in the atmosphere, and points out some corruptions which should be made, on account of refraction, in determining the heights of mountains; and in the following year he published at Zürich one which was designated 'Frage Perspektive.' But one of the most important of Lambert's works is his 'Phenomena,' 8vo, de Mensura et Gradibus Luminis, Colorum, et Umbrae, with tables and engravings, published at Augsburg in 1760. In this treatise the author states, from his own experiments, the quantities of light reflected from the exterior and interior surfaces of glass, and he gives formulæ for representing them. He considers also the effect produced on finite objects with that of the body which enlightens them; and he discusses the brightness of the image formed by a luminous body, a great deal in this last connexion being made, to calculate the degrees of illumination on the different planets; and he describes instruments for measuring the intensities of differently coloured light.

In 1761 he published at Augsburg a valuable work entitled 'Insigniores Orbitas Comotorum Proprietates,' 8vo., in which he formulates a formula for determining, in a parabolic orbit, the perihelion distance in terms of two radii vectors and the difference of the squares of them. In the 'De Hierarchia,' 4to, published at Augsburg in 1760, he points out the absurdity of these corruptions of finite objects with that of the body which enlightens them; and he discusses the brightness of the image formed by a luminous body, a great deal in this last connexion being made, to calculate the degrees of illumination on the different planets; and he describes instruments for measuring the intensities of differently coloured light.

In 1764 was published, at Leipzig, in 2 vols. 8vo., Lambert's philosophical work entitled 'Neues Organon.' This is different from his 'Phenomena'; the former is a treatise on the same subject, but more on the political side, and a system of rules for determining the policy of a country, which is intended to be a guide to the statesman. The second volume contains a political treatise on the subject of the system of a country with respect to its civil institutions, and the third is a treatise on the character of the political system of a country with respect to its constitutional institutions, the fourth is a treatise on the science of distinguishing the real from the apparent. A sort of supplement to this work was published by him at Riga in 1771, in two volumes 8vo.; and it is entitled Architektonik, and treaties of the metaphysics of mathematics; the subjects being Unity, Number, Dimensions, Continuity, Limitis, and Infinity.

The first mathematical work which Lambert published after he went to reside at Berlin was his 'Beyträge zum Gehruchte der Mathematik und deren Anwendung' (3 vols. 8vo., 1768 to 1772). The author, giving an outline of the history of mathematics, discusses the theory of numbers, and a tract on trigonometry, with notices on what is called tetragoniometry; in it are given also some remarkable propositions relating to the projections of the sphere. In the first of these propositions he introduces the inscription of a Table Écliptique formant au Tableau vrai de toutes les Éclipses, tant de la Lune que de la Terre; and in 1770 appeared his 'Propriétés de la Terre sur diverses Eclipses terrestres Tabellen,' 8vo. He was joined with Bode, Schulze, and Lagrange in the publication (1776), under the direction of the Academy of Berlin, of a 'Série de Astronomical Tables.'

Lambert also wrote a tract on 'Hygrometry,' which was published at Augsburg in 1770; and he left one on Pyrometry, which was published at Berlin, in 1779, that is after his death; this last contains a biography of the author, by Everhard. Besides these works Lambert wrote numerous papers on scientific subjects, which were published in the 'Acta Helvetin' and in the 'Mémoires' of the Academy of Berlin. Among the 'Acta' are his 'Tentamen de Vi Caloris ejusque Magnitudine,' 1762, and his 'Dimensio' of the Earth, 1767, which was afterwards published by Lagrange, and in the 'Mémoire sur les Mouvements des Eclipses de la Lune.' Among the 'Mémoires' of the Academy contain his papers on the Incommensurability of the Circumference of a Circle to its Diameter, and the Dimensions of the Earth; one was published, 1771, by the author, and which was afterwards generalised by Lagrange, and a 'Mémoire sur les Vibrateurs' by Lagrange.

Lambert was endowed with a strong memory and a fertile and well regulated imagination: his manners were simple, and he is said, in his dress, to have disregarded the fashions of the time; but he was both esteemed and beloved by those who knew him intimately. He died Sept. 25, 1777, being then only forty-nine years of age. All the manuscripts left by him were purchased by the Academy of Berlin, and were subsequently published by John Bernoulli, a grandson of the celebrated John Bernoulli of Basle.

The 'Berlin Mémoires.' Biographie Universelle.)
LAN, a genus of plants belonging to the natural order Labiatae. It has a 2-lipped corolla, the upper lip rounded, lower lip trilobed. The lateral lobes minute, tooth-like, or obsolete, rarely elongated. The anthers approach in pairs, and the filaments are stout and long. The calyx is 5-toothed and hallow, the teeth nearly equal. This genus includes the dead, blind, and dumb nettles of our peasants, so called from their resemblance to the Urtica in many points, except their sting.

L. amplexicaule has roundish corollate obtuse leaves, the lower ones stalked, the upper ones sessile and clasping; the teeth of the calyx are longer than the tube at length conic, the lateral lobes of the lower lip of the corolla toothless; the nuts small, and of an obvolute oblong shape. It is found in sandy and chalky fields in Great Britain, the North of Africa, and Middle Asia.

L. lasianum, the leaves reniform, corollate, obtuse leaves, and is distinguished by the teeth of the calyx being longer than their tube, hispid, and always spreading. The lateral lobes of the lower lip of the corolla with a short tooth, the teeth long as those of the oblong species, and is of an oblong shape. This species is common in Scotland, Sweden, and the North of Germany.

L. purpureum has a pale purplish corolla, spotted with red, the lateral lobes of the lower lip having 2 teeth. The nuts oblong, or about twice as broad as long. It is found in Great Britain and Sweden, where, according to Linnaeus, it is boiled and eaten. It was formerly used in medicine, but is not now so employed.

L. viscosum has but one tooth in the lateral lobes of the lower lip of the corolla. It is a British plant, and is likewise found in France, Germany, and Sweden.

L. elatum is distinguished by having the calyx teeth as long as the tube, all separated by acute angles, the upper one distant from the others. The corolla has 3 teeth, and is large and white. It was once used medicinally, but is now disregarded. Like L. purpureum, this species is eaten in Sweden as a pot-herb. It is found in Great Britain and the southern parts of Europe.

L. maculatum has the calyx teeth longer than their tube, the lateral lobes of the lower lip having 2 teeth. The flowers oblong, and about twice as broad as long. It is found in Great Britain and the continent of Europe.

L. striatum has deeply cut ovate leaves, the corolla 3 times as large as the calyx, which is glabrous. It is native of Greece in waste places, and is supposed by Fraas to be the Asteris herb of Dioscorides, 3. 103.

L. segetum is another species of Lamium, growing chiefly in the southern parts of Europe. They are not worth cultivation for ornament, but will easily grow in any soil or situation, and are to be propagated either by division or by seed.

LANCASTER, COUNTY PALATINE OF. [Palatinate Counties, P. C.]

LAND TAX. [Taxation, P. C.]

LANDLORD AND TENANT. [Tenant and Landlord, P. C.]

LANE, GERRARD, D.D., born in Westmoreland about 1608, was successively a servant, scholar, and fellow, of Queen's College, Oxford; and he held the place of keeper of archives to the university and provost of his college for 20 years. He died at Oxford during the summer of 1668. He was a studious and timid man, who contrived to steer through the political storms of his time without giving serious offence to any party. He edited Longinus, and published several pamphlets on church questions. But his chief usefulness was in his unprinted collections, which included several catalogues of manuscripts, often referred to by Warbey and others.

LANDEBAIE, his son, was born at Oxford in 1656, and, after having received an elementary education, was apprenticed to a bookseller in London. An elder brother dying, he was employed in soliciting books, and, in 1691, was admitted master of arts in the University of Cambridge. He bore himself however to idleness and low extravagance, and spent a great part of his property; but after a time he reformed, and retained of his earlier tastes none but his love for the theatre. He made a very large collection of old plays, amounting, as he says, to almost a thousand. He made use of these, first, in a republication of a catalogue of plays made by Kirkman, a bookseller of London, in 1690, and, secondly, in those of unprintcd, '1687, 4to. This work, specially sold off, was improved in 'A New Catalogue of English Plays,' 1688, 4to. Still further additions and amendments produced his 'Account of the English Dramatick Poets,' 1691, 8vo., 1699 (by Gilson), 1719 (by Giles Jacob, for Curi). The criticism contained in this work is shallow, prejudiced, and obsequious. The author pronounces Sir Robert Howard to be an admirable poet, and prefers Shaddwell's plays to Dryden's. But, in relating facts and describing editions, he scrupulously sets down what was before him; and although the information he gives is very incomplete, his work is the most trustworthy of our earlier attempts at a complete account of our national drama. In the British Museum is a copy of it with valuable notes by Oldys. He published also an appendix to a catalogue ofgraduates.

LANDELAIN, ROBERT. [Longland, Robert, P. C.]

LANGDONIA. [Rhiania, P. C. S.]

LANIERE, NICOLAS, a painter, engraver, and musician, who was a favourite with Charles I. He was born in 1568, and was an Italian by birth. Lanier, says Wood, 'understood hands,' by which he means that he was well versed in the handling of various masters, and was a fit person to employ in the purchase of pictures, and for whose purpose Charles frequently employed him. Wood states that he was employed in the purchase of the gallery of the Duke of Mantua, for which Charles gave 20,000l.—it comprised the Triumph of Caesar, by Mantegna. [Hampton Court Pic-
tures Gallery, P. C. S.]

Lanier was a better musician than a painter. He was appointed in 1626 Charles's chapel-master, for which he had a salary of 200l. per annum; he was also closet-keeper to Charles. There is in Ben Jonson's works a masque, which was performed in 1617 at the house of Lord Hay, for the entertainment of the French ambassador, and for which Lanier both painted the scenes and composed the music. He also designed a mask to music, which was written by Thomas Fierro for the funeral dirge of Charles I.

Lanier lived to see the dispersion of the collection which he himself had been mainly instrumental in forming. He purchased a part of Queen's Colleges at the same time the palace in 200l. : others were purchased by his brothers Jerome and Clement. Lanier appears to have been a general dealer in pictures, and, according to Sanderson (Graphic, p. 16), to have been a very serviceable, but at the same time scrupulous, for that very reason. He had a large number of passing copies as originals: the colours were obscured by soot, and he cracked the pictures by rolling them up face upwards. He purchased many pictures for Charles, and marked them with a rosette or a small figure resembling six radiating leaves—the mark is given by Walpole. Walpole buries Lanier on November 4, 1646, overlooking the somewhat glaring inconsistency of making him write the music to Charles's funeral dirge three years after his own burial: the date is not a misprint, because: Walpole adds his age—seventy-eight years; still it ought probably to be 1649 or 1656. The date of Lanier's birth (1668) is correct, because, in an engraving dated 1656 he writes himself at the juvenile age of sixty-eight—"av la eta sua giovane di sessanta-otti anni." Vandyck painted Lanier's portrait during his first visit to England, and it was this picture which induced Charles I. to request Sir Kenelm Digby to invite Vandyck back again after his departure. There is a portrait of Lanier by himself in the Music School at Oxford, with palette and brushes in his hands, and some music-notes on a piece of paper.

(Lanier, A. de. Leopold Dorn, Oberland Conisier, &c.; Walpole, Anecdotes of Painting, &c.)

LANKESTER, JOSEPH. [School, Primary, P. C.]

LANNES, JEAN, Duke of Montebello and Marshal of France, born 21st May, 1522, at Lebaucq, in Normandy. On 28th March, 1572, he captured Dunkirk; and, on 22nd June, 1574, he received the command of the fleet which captured Vlissingh. He was created Duke of Montebello, 1576; the title of Duke of Lannion, honorary, 1578; and, in 1579, he was made a cardinal. He was afterwards killed in the battle of Parnawa; and, in 1649, a number of his letters were published in Latin, at Paris.
L A N
L A N
pelon, the Duke of Wellington, and Marshal Ney and Soult. He was born of humble parents, and was at first brought up to the trade of a shoemaker. In 1792 he joined a battalion of volunteers raised in the department of Gers, of which he soon became sergeant-major. His first campaign was with the army employed on the frontiers of the Pyrenees, under the command of Lechervre, in which instance his bravery and decision gained him a promotion to the rank of "chef de brigade," which nearly corresponds to that of major among the English troops. After the political crisis of the 9th Thermidor (July 27th), 1794, he partook in the desperate attempt of the republican faction to protect the Montenotte. The attempt failed, and he was taken prisoner at the breach of the scaling-ladder, but, with the assistance of several like-minded officers, he obtained his freedom at a considerable sacrifice of his own property. His military talents were soon discovered and appreciated, and by the offers of the army he rose so rapidly in command that he was raised to the rank of demi-brigade, which nearly corresponds to that of major among the English troops. He afterwards rendered signal assistance to the capture of Toulon, and in the siege of Ciudadorgaz, which was conducted under Castaños, he was distinguished for his courage and indomitable spirit. In the battle of Aboukir, on the 1st July, 1794, he was severely wounded in the leg, but he was not kept from the service. In the affair of the Batalla de la Solana, he was engaged, and was wounded in the thigh by a ricochet shot. In the battle of the Pyrenees, he was wounded in the hand, and in the battle of Toulouse he was severely wounded in the leg. In the battle of Arcole, on the 13th November, 1796, he was struck down by a Sabre full in the face, and, though his head was cut open, yet he continued to direct the operations of the right wing of the French army. In the battle of Fleurus, on the 26th June, 1794, he was severely wounded, and his horse was killed. In the battle of Valenciennes, on the 20th November, 1794, he was severely wounded in the leg, and in the battle of Raucourt, on the 9th August, 1795, he was severely wounded in the head. In the battle of the Bicamin, on the 8th May, 1796, he was severely wounded in the leg, and in the battle of Villafria, on the 3rd May, 1797, he was severely wounded in the leg. In the battle of Rivoli, on the 14th March, 1797, he was severely wounded in the leg, and in the battle of Marengo, on the 14th June, 1799, he was severely wounded in the leg. In the battle of Aboukir, on the 1st July, 1794, he was severely wounded in the leg, and in the battle of Toulouse he was severely wounded in the head. In the battle of Arcole, on the 13th November, 1796, he was severely wounded in the head. In the battle of Fleurus, on the 26th June, 1794, he was severely wounded in the head. In the battle of Valenciennes, on the 20th November, 1794, he was severely wounded in the head. In the battle of Raucourt, on the 9th August, 1795, he was severely wounded in the head. In the battle of Bicamin, on the 8th May, 1796, he was severely wounded in the head. In the battle of Villafria, on the 3rd May, 1797, he was severely wounded in the head. In the battle of Marengo, on the 14th June, 1799, he was severely wounded in the head. In the battle of Aboukir, on the 1st July, 1794, he was severely wounded in the head. In the battle of Toulouse he was severely wounded in the head. In the battle of Arcole, on the 13th November, 1796, he was severely wounded in the head. In the battle of Fleurus, on the 26th June, 1794, he was severely wounded in the head. In the battle of Valenciennes, on the 20th November, 1794, he was severely wounded in the head. In the battle of Raucourt, on the 9th August, 1795, he was severely wounded in the head. In the battle of Bicamin, on the 8th May, 1796, he was severely wounded in the head. In the battle of Villafria, on the 3rd May, 1797, he was severely wounded in the head. In the battle of Marengo, on the 14th June, 1799, he was severely wounded in the head. In the battle of Aboukir, on the 1st July, 1794, he was severely wounded in the head. In the battle of Toulouse he was severely wounded in the head. In the battle of Arcole, on the 13th November, 1796, he was severely wounded in the head. In the battle of Fleurus, on the 26th June, 1794, he was severely wounded in the head. In the battle of Valenciennes, on the 20th November, 1794, he was severely wounded in the head. In the battle of Raucourt, on the 9th August, 1795, he was severely wounded in the head. In the battle of Bicamin, on the 8th May, 1796, he was severely wounded in the head. In the battle of Villafria, on the 3rd May, 1797, he was severely wounded in the head. In the battle of Marengo, on the 14th June, 1799, he was severely wounded in the head. In the battle of Aboukir, on the 1st July, 1794, he was severely wounded in the head. In the battle of Toulouse he was severely wounded in the head. In the battle of Arcole, on the 13th November, 1796, he was severely wounded in the head. In the battle of Fleurus, on the 26th June, 1794, he was severely wounded in the head. In the battle of Valenciennes, on the 20th November, 1794, he was severely wounded in the head. In the battle of Raucourt, on the 9th August, 1795, he was severely wounded in the head. In the battle of Bicamin, on the 8th May, 1796, he was severely wounded in the head. In the battle of Villafria, on the 3rd May, 1797, he was severely wounded in the head. In the battle of Marengo, on the 14th June, 1799, he was severely wounded in the head. In the battle of Aboukir, on the 1st July, 1794, he was severely wounded in the head. In the battle of Toulouse he was severely wounded in the head. In the battle of Arcole, on the 13th November, 1796, he was severely wounded in the head. In the battle of Fleurus, on the 26th June, 1794, he was severely wounded in the head. In the battle of Valenciennes, on the 20th November, 1794, he was severely wounded in the head. In the battle of Raucourt, on the 9th August, 1795, he was severely wounded in the head. In the battle of Bicamin, on the 8th May, 1796, he was severely wounded in the head. In the battle of Villafria, on the 3rd May, 1797, he was severely wounded in the head. In the battle of Marengo, on the 14th June, 1799, he was severely wounded in the head. In the battle of Aboukir, on the 1st July, 1794, he was severely wounded in the head. In the battle of Toulouse he was severely wounded in the head. In the battle of Arcole, on the 13th November, 1796, he was severely wounded in the head. In the battle of Fleurus, on the 26th June, 1794, he was severely wounded in the head. In the battle of Valenciennes, on the 20th November, 1794, he was severely wounded in the head. In the battle of Raucourt, on the 9th August, 1795, he was severely wounded in the head. In the battle of Bicamin, on the 8th May, 1796, he was severely wounded in the head. In the battle of Villafria, on the 3rd May, 1797, he was severely wounded in the head. In the battle of Marengo, on the 14th June, 1799, he was severely wounded in the head. In the battle of Aboukir, on the 1st July, 1794, he was severely wounded in the head. In the battle of Toulouse he was severely wounded in the head. In the battle of Arcole, on the 13th November, 1796, he was severely wounded in the head. In the battle of Fleurus, on the 26th June, 1794, he was severely wounded in the head. In the battle of Valenciennes, on the 20th November, 1794, he was severely wounded in the head. In the battle of Raucourt, on the 9th August, 1795, he was severely wounded in the head. In the battle of Bicamin, on the 8th May, 1796, he was severely wounded in the head. In the battle of Villafria, on the 3rd May, 1797, he was severely wounded in the head. In the battle of Marengo, on the 14th June, 1799, he was severely wounded in the head. In the battle of Aboukir, on the 1st July, 1794, he was severely wounded in the head. In the battle of Toulouse he was severely wounded in the head. In the battle of Arcole, on the 13th November, 1796, he was severely wounded in the head. In the battle of Fleurus, on the 26th June, 1794, he was severely wounded in the head. In the battle of Valenciennes, on the 20th November, 1794, he was severely wounded in the head. In the battle of Raucourt, on the 9th August, 1795, he was severely wounded in the head. In the battle of Bicamin, on the 8th May, 1796, he was severely wounded in the head. In the battle of Villafria, on the 3rd May, 1797, he was sever
The gallant spectacle of their leader's courage had animated, and, by this daring and decisive measure, the breach was quickly passed, and the town was gained.

The last but not least noble exploit of this distinguished general was the affair of Lobau in the sanguinary battle which has been named from it, and the grand attack on the Austrian centre, which, though unsuccessful in its results, was conducted by Lannes with great skill and enterprise. The French had come up to-redoubt their battery to the island of Lobau, their wearied bands were attacked by fresh troops, which the Archduke Charles brought up in constant succession in order to dislodge them from their position. Lannes was the first to renew the attack, and, after a succession of resisting the check, posted three of his soldiers on whom he could place most reliance in the rear of the columns, and supporting them with the troops which the emperor had sent to his assistance, seconded by Masséna, he checked the advancing numbers of the Austrians. The French had reserved their fire till the enemy had approached within a few yards of them, and then commenced a most deadly struggle.

At that critical moment Lannes had dismounted from his horse, that he might be less exposed to the sweeping fire of the Austrian artillery, when he was struck by a cannon-ball, which carried away the whole of his right leg and the foot and ankle of the left. Napoleon was directing the position of some batteries, when he beheld the almost lifeless body of his heroic marshal borne off from the battle. The last scene in the life of Lannes has been very differently related, and some of the representations of it are prodigious probability and exaggeration.

The description given by T. Illion, who, it is chiefly derived from the accurate narratives of Pelet, Savary, and Thibault, is that which appears most consonant with truth. At Lannes approached the litter that contained the shattered remains of his hero;composition, Lannes had still sufficient strength remaining to seize his hand, and, with a voice weakened by loss of blood, to bid him last adieu.

"Live," said he, "for the sake of the world, and bestow a few thoughts on one of your best friends, who is shortly to be no more." Beside the litter of his early friend, of the sharer of his perils, and the partaker of his fortunes, kneel and weep the conquerors of Europe. "Lannes," he exclaimed, "do you know me? It is the emperor, it is Bonaparte, it is your friend; you will surely yet be preserved to us." To live in order to serve you and my country is my wish," he replied, "but in an hour I shall be no more." On no occasion had Napoleon evinced such deep emotion. "Nothing," he observed to Masséna, "but so terrible a calamity could have withdrawn me from a moment for the care of the army." Critical indeed were the circumstances in which that army was then placed, and the fate of Napoleon's empire was depending on the issue; but seldom can ambition, even amid its highest efforts, stir the genuine emotions of the heart. For nine days, as had been proved, in the rapid and disheartening success during which he was constantly visited by the emperor, and on the 31st of May, 1809, he expired. At the same time had fallen with him the brave General St. Hilaire, whom, like Bayard, it had styled the knight without fear and without reproach.

Lannes, unlike many of Napoleon's generals, had acquired a constantly increasing military reputation. In the first part of his career courage predominated over judgment; but experience was daily producing in his mind a more just equilibrium between those two qualities so essential to a commander. "I found him a dwarf," said the emperor to Las Cases, "and I lost him a giant." And in another conversation with this faithful companion of his exile, he remarked of this marshal that "he had great experience in war, having been in fifty-four battles and three hundred combats. He was cool in his conduct of operations; he was ready to take advantage of any opportunity which might present itself. Violent and hasty in his temper, even in my presence, he was however ardent attached to me." His character was formed on the postures of the sovereigns of the soldiers of that period; a large sharer in the rewards which Napoleon so lavishly bestowed upon his generals, he was as prodigal of his means as of his blood. But to his credit it may be added that, a conquering officer, cause went to the relief and support of his poorer companions in arms.

Lannes had married Mademoiselle Louise de Grèhémec, a young and elegant beauty possessed of a delightful voice. When she became a widow, Napoleon evinced by the most assiduous attention to her the high respect he bore for the memory of her distinguished husband. She was afterwards appointed a lady of honour to the Empress Marie Louise. The present Duke of Montebello, Lannes' eldest son, has married an English lady, Ellen, the daughter of Charles Jenkinson, Esq.

The Military Life of Lannes, written by Mons. René Feris, was published at Paris in 1809.

LANZAROTE, [SKYLIGHT, P. C. C.]

LANTERN, MAGIC. [MAGIC LANTERN, P. C. S.]

LANZAROTE, one of the Canaries, lies about seventy miles from Cape Juby on the western coast of Africa, between 28° 60' and 29° 10' N. lat., and 18° 30' and 14° W. long. It is separated from the island of Fuertaventura, which lies south of it, by a strait which is from four to six miles wide, and is called La Boyana. Lanzarote extends in a north-east and south-west direction about thirty-one miles, with a breadth varying between five and ten miles. The area is estimated at 325 square miles, or about forty miles more than the county of Middlesex.

North of Lanzarote are five small islands: the largest are Alegranza and Graciosa, which are inhabited, and produce pears and orchillas; the others are only rocks. The strait which separates Graciosa from Lanzarote is seven miles broad, and it is in most places, than six miles wide, and is the most spacious and only safe port for large ships in the Canaries, but useless as a harbour for trade, because the coast of Lanzarote rises in a continuo succession of basaltic cliffs almost perpendicular to the height of 1400 feet. The upper part of these cliffs belong contains an extinct volcano, called La Corona, whose edges rise to the elevation of 1588 feet above the sea. From this point the rocky mass descends southward, and is surrounded by a few wide valleys which open to the south-west, and in which palm-trees and fig-trees abound. It terminates in an extensive sandy plain, which surrounds Guanapé, the capital of the island, of this place the country is covered by numerous hills surrounded by fields of fava. All these hills have a conical form, consist of scoria and ashes, and have craters. These hills were formed by a terrible eruption which took place in 1730. Such masses of lava were thrown out by them, that one-third of the island, and that the most fertile portion, was converted into a stony waste.

The streams of lava ran into the sea, owing to which the whole western shore is precipitous in the extreme, with the exception of a very small bay called Jambilo, where was once a harbour for small vessels, which by the eruption was converted into a salt-water lake. The eastern shores are neither so steep nor so barren as the western, and being surrounded by an island, called Montana Blanca, lies to the east of the lava tract, nearly in the centre of the island; it rises to 2000 feet above the sea, and is cultivated to the summit.

The centre of their island is exceedingly hilly, but during certain seasons, when the south-eastern winds, having passed over the Sahara, extend to the island: these winds frequently bring hosts of locusts with them. In spring and the early part of the summer northern and north-eastern gales are frequent; they last for several days, and blow with such violence as to prevent the growth of trees, which are only found in the valleys of the northern tract, where they are protected by the high ground north of them. Rain is scarce, and the crops are uncertain. A drought which lasted from 1768 to 1771 compelled nearly the whole population to emigrate; the water in the cisterns had entirely dried up. There is only one spring on the island, and it is very dry and arid.

Wheat, barley, Indian corn, and potatoes are extensively cultivated. In some parts are large vineyards; the grapes are of a superior flavour, and the wine of Lanzarote is preferred to that of Madeira. The principal industry of the island, as productivity, is the production of the lassara, which is obtained from the Mesembryanthemum crystallinum: this plant is indigenous, but has also become the object of extensive cultivation. In several places on the island there is a very small; they are only kept for agricruitural labour. Very few horses and mules are kept; but there are many dromedaries and asses. There are many goats and sheep. There are few hogs. Of fruits they have large fig-trees and pomegranates. They also grow vineyards. A considerable quantity is exported to the other Canaries.

The population is estimated at about 18,000 individuals. They are strong built, and of a dark complexion. Many have
black curly hair, and some features which prove that the ancient Spanish settlers have intermarried with the Moors and negroes. The Inhabitants are mostly occupied with cultivating the ground; but several families gain their livelihood by fishing. Three vessels on an average are annually sent to the coast of Africa, where the fishing-ground extends from the Bay of Cape Blanco: each vessel makes between eight and nine voyages, and has a crew of from thirty to forty men. They take chiefly cod and bream, and salt them. Salt-fish constitutes the principal food of the population.

The capital is Teguise, a small place consisting of about two hundred houses scattered over a small hill. On the eastern shore is the harbour, called Puerto del Rosario, a natural and secure harbour, formed by two rocky islets; it is about two miles long and one broad. The northern has a depth of twelve feet, and the eastern of a fifteen and a half at low-water, with a nine-feet rise of tide. The town of Arrecife is situated immediately to the southward of the port. It has several large houses and spacious streets. The population is 2500.

No foreign goods are allowed to be imported. The island receives them from Tenerife and Grand Canary. But English and American vessels resort to Puerto del Rosario to export barrils and orchillas. The exportation of the first-named article amounts annually to 3500 tons, and that of orchillas to two or three hundred barrels. The exportation of foreign vessels visiting annually the island is stated to vary between twenty-five and thirty. Lanzarote exports to Tenerife and Palma considerable quantities of grain, bran for the West India market, salt, fish, and salted brandy. The Dromedaries, imported from Corisco, are chiefly used for Timber and firewood, besides foreign articles. From the small port of Papagayo, near the southern extremity of the island, a large quantity of brandy is sent to Fuerteventura, whence distributed, ship, and cattle are received in return.

Lanzarote was the first of the Canaries which submitted to the Spaniards. They took possession of it in 1404. In the sixteenth and seventeenth centuries it was frequently laid waste by the Moors from the coast of Africa. This circumstance, with the terrible eruption of 1730, and the great dearth in 1768 to 1771, prevented the inhabitants from improving their agricultural condition. But in the middle of the eighteenth century the cultivation of the barrilla plant was introduced, and since that time the condition of the population has improved.

LAPO, ARNOLFO DI, the name by which a very celebrated and one of the most early of the Italian architects is known. He is said to have been born in 1294, and to have been the pupil of Arnolfo of Siena, and was sometimes called in Florence Jacopo Tedesco, but more frequently Lapo. This Lapo, who executed many works in Florence, died there, according to Vasari, in 1322.

The names of Arnolfo di Lapo and Lapo were not otherwise connected further than that they were contemporaries in Florence. Arnolfo was the son of Cambio, a native of Colle, and, according to Vasari, was born in 1292. Arnolfo did for building, says Vasari, what Cimabue did for painting: he was the pupil of Cimabue in design. He was the greatest architect of his time in Florence, and was the architect of many important works. The walls of Florence, which were erected in 1284, were planned by Arnolfo. He built the hall of Or San Michele, the old corn-market; the loggia and piazza de' Priori; and in 1294 he laid the foundations and built the great church of Santa Croce, now called the Chapel of St. Mary of the Cross, and the great monument of the Medici. But his greatest work is the church of Santa Maria del Fiore, or the Cathedral of Florence, of which he laid the foundations in 1298, or, according to some accounts, in 1294. He relieved the walls of the whole church, and covered part of it in, but the vast dome is the addition of Brunelleschi; it stands however on the foundations of Arnolfo, who also, according to his model, had intended to erect a dome in the shape of a perfectly conical one, with a lower angle than the enormous pile of Brunelleschi, which is one of the largest domes in the world, and but little less than the gigantic vault of St. Peter's, which is an imitation of it. [Dome, P. C.]

The church is in a complete state of preservation. The pulpit is of porphyry, and the work of Arnolfo. For the erection of this immense church, a tax of two sous per head was levied annually upon the citizens of Florence, and they were encouraged by indulgences to make donations to its building-fund. The external marble facing of the wall is the work of Arnolfo. The old municipal palace, the Palazzo della Signoria, which still exists as a part of the old palace of the Five Minor Princes, in the Piazza della Signoria, was also built by Arnolfo. And there are works by him in other Italian cities: he executed in 1285 the marble tabernacle of the Basilica of San Paolo, without the walls, at Rome; and shortly before 1300 he designed and executed the monument of the Cardinal de Braye in the church of San Donnino at Orretto.

Arnolfo died, according to Vasari, in 1300, aged therefrom sixty-eight, and not sixty-four, as says, if the year of his birth as given by Vasari himself be correct. Arnolfo's portrait by Giotto is in the picture of the death of San Francesco, in the church of San Croce at Florence: it is one of the group of figures conversing together in the foreground.

(Vasari, "Vite de' Pintori, &c.; Richa, "Delle Classi di Ficenze; Rumohr, "Italienische Forschungen.")

LAPP, a genus of plants belonging to the natural order Composite, the sub-order Tubuliflorae, the tribe Eremosporideae, and the sub-tribe Carrionae. It has an equal and many-flowered homogamous head, a globose involucre, with imbricated coriaceous scales. The receptacle is rather fleshy, flat, and with stamens and florets in two rows. The corollas are 5-lobed, regular, and with a 10-nerve tube. The stamens have papilliform filaments, with anthers terminating in filiform appendages. The fruit is oblong, laterally compressed, smooth, and transversely wrinkled.

L. minor has a tapering fleshy root, an erect stem, 3 feet or more in height, solid, leafy, round, and with many wide-spreading branches. The leaves are stalked, broad, heart-shaped, and being 3-ribbed at the base, somewhat hairy and downy beneath. The florets are axillary, with their anthers and stigmas purple. When in flower the involucre readily breaks from the stalk, and is known in the country by the name of a flor. It is an admirable herb for making and dressing the hair and clothing of those who pass by, and it is almost impossible to become free from it without breaking the scales asunder and scattering the fruit. The root is reckoned tonic, appetizing, and diuretic. It has had some hold as a remedy in rheumatism and diseases of the skin. Sir Robert Walpole recommends it as a remedy in gout, and some have used it as an excellent substitute for asparagus. The fruit is bitter and slightly acid, and has been prescribed as a diuretic. It grows in waste places throughout Europe and the West of Asia.

L. senor and L. tenentia are species which are found in Germany and Switzerland, but not used in the arts or in medicine.

(Lindley, "Flora Medica; Koch, "Synopsis Flora Germannica.")

LAP'SANA, a genus of plants belonging to the natural order Composite, the sub-order Liliiflorae, the tribe Acanthaceae, and the sub-tribe Lampsane. There is but one British species of this genus—

L. commutata, an annual herb. It has scutate or lobed stalked leaves, the lower leaves lanceolate; the involucres glabrous and angular; the stem panicked. The stem is from one to three feet in height, branched above, with yellow small-headed florets. It is found in waste uncultivated land, and derives its common name from its reputation in village medicine, as a soothing application to inflamed nipples, and is used in many of our provinces as an external application in wounds and abrasions.

L. fistula is a species of this genus, which grows in Switzerland and the regions of the Alps.

(Waddington, "Manual of British Botany; Koch, "Synopsis Flora Germanica.")

LAPSE. [BRENNICE, P. C.]

LARZIBIAULA, a genus of plants belonging to the natural order Malvaceae, and the tribe Mimosaceae, after Michael Lardizabal, of Urbe, a Spanish naturalist. It has dacieous or polycymous flowers. The sepals and petals disposed in a ternary order in 2 or 3 series. The stamens 6, monadelphous, and scaled, 3- or 6-foled, the anthers bithecous. The pulp of the fruit sweet and edible. It has leaves 2-5 ternate; the leaflets obtuse, acute, unequal at the base, a little toothed; two large uncorally carinate bony hairs situated at the base: the wood a pale reddish. This plant is inUNK about Anasco. It has a native Chili of woods at Concepcion, also in Peru about Arimo. It has an edible fruit, which is gathered and

P. C. S., No. 106
in the markets of Chili and Peru. The pulp of the fruit is sweet and grateful to the taste. It is called in Peru Aguil-bougni and Guibougni; and by the baron, L. Larrey, L. trifolii and L. trifolii are climbing plants, natives of Chili and Peru, but their fruits are not eaten.

(L'Anpr 1821. Dictionnaire de Larrey) LARREY, DOMINIQUE-JEAN, BARON, was born at Beauce, near Bagnères de Bigorre, in France, in July, 1786. He studied the elements of medicine and surgery at the hospital of Toulouse, under the direction of his uncle, the baron, L. Larrey, who practised medicine in that city. In 1787 he went to study his profession in Paris, and obtained the appointment of surgeon to the frigiate Vigilante, in which he visited North America. Grandfathered to Paris at the commencement of the Revolution, and in 1792 joined the French army which was then carrying on its operations on the Rhine. Here he distinguished himself by the invention of the ambulances volantes, by means of which the wounded, being first dressed, were carried off the field of battle, even under the fire of batteries. He was at the siege of Toulon, where he became acquainted with Napoleon Bonaparte, who was then a lieutenant of artillery. In 1796 he was appointed professor in the school of medicine and military surgery at Val de Grace. In 1798 he accompanied the French army with Napoleon to Egypt, and on his return published an historical and surgical memoir of the campaign. [Rela- surgie de l'Expedition de l'Armee d'Orient et en Syrie, ed., Paris, 1803. From this time he was ad- vanced to various honourable positions; after the battle of Wagram, in 1809, he was appointed a Baron of the Empire; in 1812 he was made surgeon-in-chief of the imperial army. He helped, says Mr. Arrott, in the Hibernian edition for 1841, to be published under the title of Nautical which he had earned, was that of a childish vanity; for he knew that neither the chance of birth nor the favour of a court had made him a baron, but that the dignity had been bestowed by a discriminating hand which never conferred honours upon incompetence or ineffi- ciency.

An anecdote is related of Larrey which shows his courage, and proves that he did not obtain the good graces of the Em- peror by any mechanism of character. After the battle of Wagram and Wurtzberg it was suggested to Bonaparte that the number of the wounded had been increased by voluntary nut- tation. He immediately ordered that the suspected, to the number of 280, should be separated from the rest to be ex- amined by the surgeons, and if found guilty they should be shot. Nobody doubted the guilt of the parties, and great anxiety was shown to put the sentence into execution, when Larrey demanded time to examine the suspected persons accu- rately, and to learn what still should be known. He addressed a report to Napoleon, expecting that his dismissal would follow. The contrary was the case, for Napoleon wrote a letter in return to the number of 6000 francs, and the warrant of a pension of 5000 to be paid from his own private purse. Napoleon bequeathed to Larrey at his death 10,000 francs, at the same time expressing his convic- tion that "Larrey was the most virtuous man he had ever known."

Larrey published many works besides that above referred to, which contain a great mass of valuable surgical observations. One of his earliest publications was his 'Dissertation sur les Amputations des Membres a la suite des coups de feu, et de diverses operations," Paris, 1790. In this work he demonstrated the necessity of immediate amputation after gun-shot wounds, and clearly pointed out the cases in which it was indicated. The propriety of such a practice had been previously suggested, but it is to Larrey that we are indebted for carrying it largely into effect. It was at one time the prac- tice of surgeons in cases of mortification after a wound, prevailing to performing amputation, for the line of demarcation to form between the diseased and sound parts. Larrey proved that in cases of gun-shot wounds, the best practice consisted in operating immediately after the reception of the wound.

In addition to these works he published 'Memoires de Chirurgie militaire et Campagne," ed., Paris, 1812; "Recueil de Memoires de Chirurgie," ed., Paris, 1821. A multi- volume series of these and other journals of France, the Bulletins of the Academy of Paris, and other volumes, on almost every department of surgery, bear testimony to his industry and talent, and the enlightened principles on which he was based the practice of his profession. Some of these have been translated into most of the languages of Europe, and have obtained for Larrey a first position among modern surgeons. He died at Lyon, on the 25th of July, 1841.

(London Medical Gazette, 1841; Kallisen, Medicinales Schriften—Leiden; Lancet, 1841.) LASERPIETUM (the name of the ancient Silphium), a genus of plants belonging to the natural order Umbelliferae. It has a calyx with a 5-toothed rim; the petals obsolete, imbricate, with 5 or 6 shorter lobes; the fruit compressed from the 4- or 5-angled, 8-winged, that is, the half-fruits with 5 primary stiff-ridged, and 4 winged secondary ones; a vitta in the channel below each secondary ridge. The species are herbaceous, plants, with 2-3-pinnate leaves, some with heart-shaped lobes; the flowers showy umbels; the involucres many-leaved; the flowers white, rarely yellow.

L. glabrum, glabrous Laserwort, has bilobed leaves, quite glabrous in every part; the leaflets obliquely coriaceous, here and there mucronate and toothed; leaves of the involucres acuminate; of the involucres acuminat; wings of the fruit equal, rather curved. This plant is a native of the mountains of Europe in dry and rocky places. It attains a height of one or two feet on the Alps, but in cultivation is a much larger plant. The root is filled with a gum-resin, which is acrid, bitter, and even somewhat injurious, in the 18th century. The French call it Turbex Montagnes and Turbex Vertic.

L. Silur has bilobed quite glabrous leaves; lobe-lanceolate or oval, quite entire, mucronate, sometimes confluent, and the base of the leaves of the involucres linear-lanceolate, slightly acuminate, the wings of the fruit narrow. It is a native of the mountains of the middle and south of Europe. The root is extremely bitter, and yields an aromatic resinous substance which has been supposed to be the Silicone or Silyer of the ancients, (Silicium, P. C.; LARREY, P. C.) L. Silur is supposed by Frass to be identical with the Arctaria of Dioscorides, 3, 51. Sibthorp found this plant in Greece, "L. uniflorum," a native of Portugal and Spain, and also yields a gum-resin. One of the species of Laserpitium described, and many of them yield a gum-resin, which is one of the secretions of the order to which it belongs.

(Lindley, Flora Medicina; Don, Gardn's Dictionary; Frass, Synopsis Plantarum Flora Clasica.) LASTRICA, a genus of Fenns, belonging to the tribe Aspleni. It has a robust inflorescence attached by the sinus, the veins distinct after leaving the midrib, and not similar with those of the adjoining pinnate.

The following species of this genus are described in Bagnalls Manual of British Botany: L. Thelyphora (Marsh Fern); L. Lyriscus; L. Filsus Mas (Male Fern); L. cristata; L. rigidula; and L. dilatata. For the properties, &c. of the more important of these species see Asplenium, p. 476. LA THORIE, C. B. TURING, P. C., p. 418; Earthwork, p. C. P., p. 244; Pottery, P. C., pp. 472, 473.) LATHYRUS. [Viciae, P. C.] LAVATERRA, in honour of one of the two Lavaters, a genus of plants belonging to the natural order Malvaceae. It has numerous styles, a double calyx, the outer one being three- leafed, the inner five-leafed; the capsules orbicular and many-seeded; the cells circularly arranged, and one-seeded.

L. arborea (Tree Mallow) has a woody stem, the leaves seven-angled, plaited, and downy; the pedicels aggregative, axillary, one-flowered, and much shorter than the pedicel. It is a native of Italy, Spain, Portugal, the north of Africa, and the Canary Islands, on waste places; also in Britain, in the Isle of Wight, on Portland Island, in Cornwall, and Devon- shire. It is the Malva of Theophrastus (Hist. Pl., i, 1; 4, 8).

L. neapolitana has an herbaceous scabrous erect stem, with roundish-nerved leaves, and seven blunt crested lobes; the pedicels axillary and aggregative, the involucres shorter than the calyx lobes, and slightly calyx-like. The flowers are blue with obovate petals. This species is the native of Naples, by the sea-side, and is much cultivated in our own gardens as an ornamental plant.

L. officinalis, a shrubby plant, many-branched, from distant fascicles of hairs; the leaves are soft, woolly, five-lobed, the upper ones three-lobed, with the middle lobe elongated; the uppermost leaves are oblong, almost undivided, the flowers small, solitary, calyx-like. It is a native of Provence, in hedges about D'Ieiras.

None of the species of Lavatera are of any importance or
value, excepting as ornamental plants. Many of them are indigenous and of the most conspicuous variety. The greenbough and frame species will thrive well in a mixture of loam and peat, or any light soil; they may be planted out during the summer against a south wall, and if protected in the winter from the frost, will continue to grow throughout the year. The perennial species grow in every kind of soil, and may be propagated either by dividing the plants at the root or by seeds. The annual and biennial kinds should be sown in the open border during the spring. The species chiefly worth cultivation in gardens are L. Odan, Anna, unguiculata, Nempskiana, Cretica, Luteanica, and trimestris.

LA W. CRIMINAL. The object of the English as of every other system of Criminal Law is the prevention of injuries by the terror of punishment; but it is not every injury the commission of which the law thinks fit to prevent by such means; in most cases it is satisfied with the redress of injuries after they have been committed, by either restoring the party injured to his rights, where that is possible, or by giving him compensation in damages. In an law, an injury is any violation of a legal right or omission of a legal duty: a crime, then, may be defined to be such a violation or omission of a legal duty as subjects the person guilty of it to punishment by the authority of some sovereign or by any armed body of men, the authority whose redress only have, in England, been usually denominated civil as contradistinguished from crimes. It is to be observed however, that, in strictness, every crime includes an injury or wrong to a person, and that if every injury, or wrong to a person, be entitled to redress. In felony, indeed, such injury is said to be merged in the crime; but this doctrine appears to have originated in the circumstance of all felonies having, with one or two exceptions, been originally punishable with death and having worked a forfeiture of all the offender's property, and so rendered redress impossible.

Crimes, according to the English law, are divisible into two great classes, viz. those based upon the mode of proceeding peculiar to each, viz. into

1st. Such as are punishable on indictment or information (the common law methods of proceeding).

2ndly. Such as are punishable on summary conviction before a justice or justices of the peace or other authorized persons, without the intervention of a jury (a mode of proceedings derived entirely from special statutory enactments).

It is proposed, in the first place, to treat of offences punishable on indictment or information, and afterwards to shortly refer to those punishable on summary conviction.

Offences punishable on Indictment or Information.

Indictable offences are distributable into four classes or divisions, viz.: 

1. Treasons, Præmunires, Felonies, and Misdemeanors. Persons who commit the offences which constitute the last-mentioned division shall be prosecuted by criminal information instead of being indicted.

The distinction between these classes is, for the most part, a merely arbitrary one, without any apparent reference to rule or privilege. Nevertheless, it is an established fact, that inquests in their nature wholly indistinguishable, are, in many instances, separated and subjected to punishments widely disproportionate, and to forms of procedure widely dissimilar. In fact, the only real distinguishing feature between one class of crimes and another, at the present day, is to be found in certain peculiarities of punishment and procedure incident to each. Formerly, however, the classes of crimes were marked by distinctive characteristics; but they have subsequently, by artificial constructions of the courts or by legislative enactment, been made to embrace offences of a very different nature from those originally included within them. For instance, the crime of treason, whether high or petit, implied a violation of the allegiance due from an inferior to a superior. In the case of high treason, so called by way of eminent distinction, the violation of the allegiance due from his liege lord and sovereign; and in case of petit treason, which was limited to the murder of a husband by his wife, a master by his servant, or an ecclesiastical by his inferior who owed the faith of his order, the breach of the allegiance of private and domestic faith. The characteristic above pointed out can no longer be traced in many of the various constructive treasons which have been from time to time created by the courts. It will be sufficient here to give a single illustration of the mode in which the law has been adapted to reach cases totally inconsistent with its original design. By one of the clauses of the statute of treasons (25 Edw. III. c. 2) it is declared to be treason to levy war against the king. A riotous assembly attempting to be armed by force to redress an injury, has been held to be a levying of war within the meaning of this clause, although there has been no direct intention or design whatever to levy war against the king. This construction is said to depend upon the generality of the design. If the intention be to call down particular inclosures or meeting-houses only, the offence is a mere riot, and in quality a simple misdemeanor. Though the generality of the design may be a reason for awarding a higher reward than in the former than in the latter case, there appears to be no foundation in reason or principle for construing an offence, which but for such generality would be a misdemeanor only, to amount to the crime of treason in levying war against the king. The Criminal Law Commissioners (4th, 5th, and 6th Reports) have recommended that this offence should no longer be considered to fall within the term of treason. They propose that the only assemblings or meetings of the people which should amount to a levying of war against the king should be such as are against the person of the king, or against his government or authority, or with intent to do him bodily harm, or impose any restraint upon his person, or to depossess him, or to dispossess or deprive him of any portion of his dominions or his royal authority, or to prevent him by force or violence from changing his measures or counsels, or to put any force or constraint upon or to intimidate or overawe both houses or either house of parliament; and that no assembling or rising of the people should by reason of any illegality or general purpose be deemed to be a levying of war against the king, unless it be with one or other of the several intentions before mentioned. Such riotous and tumultuous meetings as have no such intention in view should be recommended as misdemeanors merely, according to the circumstances by which they are attended.

Again, the term 'Treason' was originally applied to offences which consisted in the introduction of any foreign jurisdiction, more especially the authority of the See of Rome, into the kingdom; but has subsequently, to use the language of Mr. Benjamin Hawkins ('Plea of the Crown', b. 1, c. 19), been applied to other heinous crimes, for the most part having relation to the offences originally coming under the notion of treason, but in some instances none at all. The Habeas Corpus Act (21 Car. II. c. 12) contains an instance of the latter meaning of the word. By the 21st section of that act it is made a Treason to send any inhabitant of England, Wales, or the town of Berwick-upon-Tweed, a prisoner beyond the seas in defiance of its provisions to the contrary.

The term 'Præmunire' was adopted from the first word of the original writ on which the subsequent proceedings were founded: 'Præmunire (for præmuniri) facias A. B. quod sit ad rem publicam.' As a term of the common law of England, the phrase 'Præmunires' or 'Præmunire' was in the 18th century, sanctioned by the Customary Law Commissioners propose to abolish præmunires as a class of crimes.

The term 'Præmunire' was adopted from the first word of the original writ on which the subsequent proceedings were founded: 'Præmunire (for præmuniri) facias A. B. quod sit ad rem publicam.' As a term of the common law of England, the phrase 'Præmunires' or 'Præmunire' was in the 18th century, sanctioned by the Customary Law Commissioners propose to abolish præmunires as a class of crimes.

The crime of felony had its origin in very remote times, and was founded upon feudal principles. Its incidents were not formerly, as they are now, of a merely arbitrary nature, peremptorily annexed to certain criminal acts without reference to rule or principle. The crime originally consisted in a violation of the feudal contract by the infeudation of the lord or of the tenant; and where committed by the tenant, occasioned as a consequence the forfeiture of his hold to the lord. (4 Black. Comm., p. 96; 4th and 7th Reps. of Crim. Law Commrs.)

Those crimes, therefore, which induced such forfeiture, and, by a small deviation from the original sense, those which induced the forfeiture of goods and lands, were, by the term felony, long used to the crime felony came to signify the actual crime itself, and not the penal consequence. 'So that, upon the whole,' to use the words of Mr. Justice Blackstone (4 Com. El. St., 10) in his study of the origin of the word felony, seems to be that which is before laid down, viz. an offence which occasions a total forfeiture of either lands or goods, or both, at the common law; and to which capital or other punishment might be upheld, the crime of felony, for the violation of the law of guilt.' Where the punishment is less than capital, the offender loses his goods only; where capital, his lands as
is only, and the judge shall sentence the jury and shall stipulate for all the evidence for the crown which is admissible, and shall deliver it to the crown in the order in which it is placed in the record, and shall be bound by the same. And if a female, that the offender be drawn to the place of execution and be there hanged by the neck until dead; and that afterwards the head be severed from the body of such offender, and the body be divided into four quarters, to be disposed of as is directed in the manner of the body of a male. The judgment of death in the case of treason is that the court shall proceed immediately to the execution of the sentence of death, and shall be executed by the sentence of the court, and shall be committed to the charge of the sheriff of the county, and shall be executed in the manner therein. And if a female, that the offender be drawn to the place of execution and be there hanged by the neck until dead (30 Geo. III. c. 48, s. 1). The queen, however, may, by warrant under her sign manual, countersigned by a principal secretary of state, direct, where the offender is a male, that he shall not be drawn, but taken in such manner as the queen shall direct, and the warrant shall be sent to the sheriff of the county; and that he shall remain in prison at the king's pleasure, or, as other authorities have it, during life. These penalties were first imposed by the Statute 16 Hen. II. c. 5 (commonly called the Statute of Treason); and it is by reference to that statute that all subsequent penalties have been made punishable. It was formerly supposed that a person convicted of treason, being put out of the king's protection, might be killed with impunity, as being the king's enemy; but by the 5 Eliz. c. 1, ss. 21 and 22, it was enacted that it should not be lawful to kill any person attainted in a treason, saving such pains of death or other hurt or punishment as theretofore might, without such danger to the person accused, be inflicted upon persons apprehended. When the above penal consequences incident to the whole body of offences constituting each class will be first stated, and what in respect of those consequences differ from a capital treason. The classes will be taken in the same order as above.

1. Treason—Treasons, with one exception mentioned below, are capitulated: but whether capital or not, the offender, upon being convicted, is made liable to the crown for the punishment of:—

(a) Civil description, whether in action or possession, or settled by way of trust, which the offender has otherwise than as an executor (Civ. Cas, 568, or a trustee, or a mortgagee (4 & 5 Will. IV. c. 23, s. 3) at the time of conviction; and in the case of capital treasoms, upon attaint by judgment of death or outlawry, the blood of the offender is corrupted, but so not to obstruct descent to such offender's posterity, when such is the object of the act of wrongdoing, to a remote ancestor (5 & 4 Wm. IV. c. 106, s. 10), and all the freehold lands and tenements of inheritance in fee-simple or fee-fait, and all other hereditaments (except copyholds), which are obstructed, and which the party of right of entry on freehold lands and tenements which the offender has (otherwise than as a trustee or mortgagee, 4 & 5 Wm. IV. c. 23, s. 3) at the time of the offences committed or at any time afterwards, and also the profits of all freehold lands and tenements which the offender has in his or her own right for life, so long as such interest shall subsist, and, if the offender be a male, his wife's dower, are forfeited to the crown (4 & 5 W. Comm. 381). 26 Hen. VIII. c. 13, s. 5; 33 Hen. VIII. c. 20, s. 2; and 5 & 6 Edw. VI. c. 11, ss. 9 and 13); and all the copyhold estates belonging to the offender at the time of the offence committed are forfeited to the crown (3 & 4 W. IV. c. 106, s. 12, and 4 W. IV. c. 23, s. 3). All the above penal consequences are general to all capital treasons, unless, as is sometimes the case, the act which creates the particular treason expressly exempts from some of them. The nature of the punishment of a non-capital treason is the party guilty of treason is liable to those only of the above consequences which accrue upon conviction, since the others follow only upon the party's being attained, that is, sentenced to death or outlawry, which latter, in the case of treasons and felonies, is of the same effect as being sentenced to death. The existence of this non-capital treason would appear to be the result of inadvertence. By the Forcibull Consolidation Act (11 Geo. IV. & 1 W. IV. c. 1) it was declared to be treason and punishable with death to forge the great and other royal seals and the sign manual. By the 2 & 3 Wm. IV. c. 123, the punishment of death was repeated for forgery in all but the two cases of wills and powers of attorney to trustees stock (it has been since taken away in these cases also by the 7 Wm. IV. & 1 Vict. c. 84); but the quality of the offences amounted in the Forcibull Consolidation Act was left without alteration; so that to forge the royal seals, it would appear to be still treason, though no longer a capital offence.

The judgment of death in the case of treason is that the court shall proceed immediately to the execution of the sentence of death, and shall be executed by the sentence of the court, and shall be committed to the charge of the sheriff of the county, and shall be executed in the manner therein. And if a female, that the offender be drawn to the place of execution and be there hanged by the neck until dead (54 Geo. III. c. 146, s. 2).
have been confined after conviction. (2 & 3 Will. IV. c. 75, s. 18; 4 & 5 & 6 Will. IV. c. 86.) The court however is empowered to order such a defendant to be recommended to the royal mercy, to abstain from pronouncing judgment of death upon him, and to order such judgment to be entered of record instead; and the judgment so entered is not to have the force of one at law, but is thereupon reversed. (4 Geo. IV. c. 48, ss. 1 & 2; 6 & 7 Will. IV. c. 30, s. 2.)

4. Misdemeanors.—The punishment in the case of misdemeanors is not one specially provided by statute, is generally fine and imprisonment.

From what has been stated, it will be seen that the circumstances, so far as punishment is concerned, which distinguish offenses in their legislative arrangement and in their due process of law, are the presence or absence of forfeiture as a consequence of conviction. The distinction between misdemeanors and felonies (which term, it should be remarked, in its largest sense, includes treasons, on account of the forfeiture which that class of crimes occasions) is, that the forfeiture which ensues upon a conviction of the former is, as before observed, in pursuance of statutable provisions; whereas in the latter, it is a common law consequence of the offense, and follows as a matter of course whenever a crime is declared to be a felony.

There appears to be no distinction as regards punishment, in the case of capital and non-capital offenses, as regards the form of capital and non-capital felonies (the term is used here in its ordinary restricted sense) and the non-capital treason above described; but the difference between felonies and treasons when punishable with death was, that whereas the former offended by fee simple, attainer, forfeits to the crown the profits only of such freehold and copyhold lands as he had at the time of committing the offense, during his life, and after his death, his copyholds in fee-simple are forfeited to the lord of the manor; and even where attainted of murder, though his freehold estates in fee-simple fall after his death, it is not as a consequence of the law of forfeiture, but because they escheat for want of heirs capable of succeeding to them, owing to his blood being corrupted by the attainer; and it is on account of such estates eschatising and not being forfeited that they go to the lord of the fee (that is, subject to the crown's, year, and waste, and not to the crown, unless there appears to be an intermediate lord between the offender and the crown, in which event the crown takes as ultimate lord of the fee.

In the case of treason, however, the offender upon attaint, instead of forfeiting to the crown the profits merely of such freehold lands as he had at the time of committing the offense, during his life, forfeits all freehold estates of inheritance, as well those in fee-tail as those in fee-simple, and not only with the profits of the like freehold estates of the offense, but all which he may acquire at any time afterwards; and instead of forfeiting to the crown the profits of his copyholds during his life, and to the lord of the manor his copyholds on his death, he is deprived of the benefits of the tenure of the manor all the copyholds belonging to him at the time the offense was committed. Where the offender is a male, his wife's dowry is also forfeited to the crown, which is not the case in respect of a male forfeiter. This power is now empowere (59 Geo. III. c. 94) to restore the whole or any part of any lands or hereditaments to which it becomes entitled by escheat or forfeiture to the family of the offender, a provision which has greatly mitigated the hardship of the law of forfeiture. The Criminal Law Commissions however recommend the entire abolition of the confiscation of property as a necessary incidental to convictions for treason or felony. (Sixth Report on Criminal Law.)

The difference between the judgment of death for treason and that for felony requires no comment.

Besides the above peculiarities of punishment, these offenses differ also in the penalties attendant upon conviction by virtue of the nature of the procedure; but it will be more convenient to refer to these when describing our general system of criminal procedure.

Having pointed out the leading characteristics of the various classes into which such crimes are divisible by the law of England, it is now proposed to state shortly what are the different offenses comprised under each of those classes.

In this view the offenses belonging to each class are arranged under their several subdivisions. The order has been taken in the same order as before. It will be proper, however, in the first instance, to show what persons are capable of committing crimes, to notice one or two provisions of general application, for the purpose of avoiding repetition, and to make a few explanatory observations.

According to the law of England, all persons above the age of seven years, except such as by reason of unripeness, of infancy, of infancy, or decreas'd notoriety, were not capable of discerning, at the time they do an act, that the act is contrary either to the law of God or the law of the land, are criminally responsible for such act; but temporary incapacity willfully homicide by intoxication or other not a sufficient excuse. An infant of the age of seven and under fourteen years, however, is to be presumed to be incapable of committing a crime until the contrary be proved. Duress, also, inducting a well-grounded fear of death or of suffering, will excuse a person acting under such duress in all cases except treason and murder; and a married woman committing any offense, except those last mentioned, if her husband be present at the time, shall be presumed to have acted under his coercion, and be entitled to an acquittal, unless it appear that she did not so act. A married woman also shall not be liable to conviction for receiving her husband or any other person in his presence and by his authority.

The following provisions are of general application. By the stat. 7 Will. IV. & 1 Vict. c. 90, s. 5, it is enacted that no court shall direct any offender to be kept in solitary confinement for any longer period than three months in the space of one year. Whenever, therefore, in the following statement solitary confinement is mentioned as part of the punishment for any offense, the periods during which it may be inflicted are to be understood as regulated by the above provision.

By the statute 7 Will. IV. & 1 Vict. c. 85, s. 11, power is given to the jury on the trial of any person for any felony whatever, where the crime charged shall include an assault against the person, to acquit of the felony, and to find a verdict of guilt of assault against the person indicted, if the evidence shall warrant such finding; and thereupon the court may imprison the person so found guilty of an assault for any term not exceeding three years, without or with hard labour or solitary confinement, or with both.

By the stat. 1 Geo. IV. c. 57, s. 3, it is provided that where the whipping of whipping on female offenders formed, before the passing of that act, the whole or part of the sentence to be pronounced, the court may pass sentence of confinement to hard labour for any time not exceeding six months nor less than one month, or of solitary confinement, in lieu of the sentence of being whipped. In all cases, therefore, where whipping is mentioned to be part of the punishment, the court is being restricted to make, the above provision operates.

By the stat. 3 & 4 Vict. c. 111, made perpetual by 5 & 6 Vict. c. 85, members of joint-stock or other banking companies, the leading officers of which are accused of any crimes against or with intent to injure or defraud such co-partnerships, are made liable to the same punishments as if they had not been or were not members of such co-partnerships.

In the following cases it is described only of any particular offence. It is to be observed, however, that where a crime is defined by statute, the enactment in most cases comprises, in fact, many others distinct from the general one, though in nature connected with it. For the details of such enactments, reference must be made to the statutes cited at the end of each offence. With respect to these statutes, those which define the crime, as well as those which declare the punishment, are referred to where the statutes are distinct, and these are arranged as regards any particular crime in the order of date; and generally, but not universally, where statutes of both descriptions are preferred to those which are distinct, they are so arranged that the former statute is always the first in order. The following statement contains no offence contained in any merely temporary act, or in any local or private act, of a date subsequent to the period since which those such acts have been printed separately into the public general acts.

I. TreaSon.—(Capital.)

The following treasons are punishable with death, viz.:—

1. Compassing the death of the king (which term includes a queen regnant) of the time of the king, or of his heir apparent.
violation of the king's companions, (i.e. his wife during the coverture,) or the king's eldest daughter unmarried, or the wife of the king's eldest son and heir; levying war against the king in his realm, or being adherent to the king's enemies in his realm, and going or being in the realm or elsewhere, and being thereof attained of open deed; or slaying the chancellor, treasurer, or the king's justices of the one bench or the other; justices in eyre or justices of assize, or any other justices assigned to hear and determine, being in their places doing their offices. 
(25 Edw. III. st. 5. c. 2.)

2. Endavouring to prevent the person next in succession to the crown, according to the Acts of Settlement, from succeeding thereto. (Anne, st. 2. c. 17. s. 1.)

3. Affirming, by writing or printing, that any other person has a right to the crown otherwise than according to the Acts of Settlement and the Acts for the Union of England and Scotland; or that the crown, with the authority of parliament, is unable to limit the descent of the crown. (6 Anne, c. 7. s. 1.)

4. Compeasing or intending the death or destruction, or any bodily harm tending to death or destruction, to any person wounding, imprisionment or restraint of the person of the king; or to deprive or depose him from the crown; or to levy war against him, within the realm, in order to compel him to change his measures or counsels, or in order to overawe the parliament; or to move any foreigner to invade any of the British dominions; such compoeasing or intention being expressed by publishing some printing or writing, or by some overt act contrary to Geo. III. c. 7. s. 1, made perpetual by 57 Geo. III. c. 6.)

5. Being married to, or being concerned in procuring the marriage of any issue of her present majesty whilst such issue are under 14 years of age: (Anne, c. 6. s. 1.)

6. Knowing any person to have committed any of the before-mentioned capital treasons, receiving, relieving, comforting or assisting him, or aiding his escape from custody.

7. Bringing into the realm papal bulls or other writings or instruments from the See of Rome; or publishing and writing in use any such bulls, writings or instruments. 
(18 Eliz. c. 2. ss. 2 and 3.)

Besides the last-mentioned offence, there also existed till very recently several other capital treasons relating to the See of Rome; but these were repealed by the 7 & 8 Vict. c. 102.

Treason.—(Non-Capital.)

The following treason (the one already alluded to) is punishable with transportation for life or not less than seven years, or with imprisonment for any term not exceeding seven years, or with and without hard labour or solitary confinement, or with both, viz. :

1. Forgery of the great seal, her majesty's privy seal, or any part thereof; or defacing, mutilating, the royal seal, or any copy or impression thereof, the seal being appointed to be used in Scotland, and the great and privy seals of Ireland. 
(11 Geo. IV. & 1 Wm. IV. c. 66. s. 2; 2 & 3 Wm. IV. c. 123; 3 & 4 Wm. IV. c. 44. s. 3; 7 Wm. IV. & 1 Vict. c. 84. ss. 2 and 3.)

11. Premises.

The following are the offences coming under this denomination still in force :

1. Derogating from the queen's courts. (27 Edw. III. st. 1. c. 1. s. 1.)

2. Deans and chapters omitting to elect a bishop; and archbishops or bishops to consecrate the person so elected after receiving the queen's congé d'elire. 
(25 Hen. VIII. c. 20. s. 7; repealed by 1 & 2 Philip and Mary, c. 8, and revived by 1 Eliz. c. 7.)

3. Making the assizes of abbey lands contrary to the provisions of 1 & 2 Philip and Mary, c. 8. 
(1 & 2 Phil. and Mary, c. 8. s. 40.)

4. Obtaining any stay of proceedings, other than by arrest of judgment or writ of error, in suits for monopolies. 
(21 Jac. I. c. 5. s. 4.)

5. Procuring any stay of proceedings, other than by the authority of the court, in actions brought against persons for making provision or purveyance for the crown. 
(12 Car. II. c. 24. s. 14.)

6. Attempting maliciously and advisedly, by speaking or writing, that both Houses or either House of Parliament has a legislative authority without the crown. 
(13 Car. II. c. 1. s. 3.)

7. Sending any subject of the realm a prisoner beyond the seas in defiance of the Habene Corps Act. 
(31 Car. II. c. 2. s. 12.)

8. Asserting, maliciously and directly, by preaching, teaching or advising speaking, that any person, other than according to the Acts of Settlement and Union, has any right to the throne of these kingdoms, or that the crown and parliament cannot make laws to limit the descent of the crown. 
(6 Anne, c. 11. s. 1.)

9. Knowingly and wilfully solemnizing, assisting or being present at, any marriage forbidden by the Royal Marriage Act. 
(12 Geo. III. c. 11. s. 3.)

10. Aiding, comforting or maintaining persons who bring into the realm papal bulls or other writings or instruments from the See of Rome, to the intent to uphold the jurisdiction or authority of the pope. 
(18 Eliz. c. 2. s. 4.)

III. Felonies.—(Capital.)

The following felonies are punishable with death, viz. :

1. Destroying ships of war or her majesty's arsenals, dockyards, magazines, custom houses, castles, forts or other naval establishments, or other ammunition of war, &c. 
(12 Geo. III. c. 24. s. 1.)

2. Murder. 
(9 Geo. IV. c. 81. s. 3.)

3. Unnatural offences. 
(9 Geo. IV. c. 81. s. 15.)

4. Attempting to murder the king, or to destroy the government, or to commit any other treason against the crown. 
(16 Geo. III. & 1 Wm. IV. c. 16. s. 2.)

5. Robbery, aggravated by wounding the person robbed. 
(7 Wm. IV. & 1 Vict. c. 87. s. 2.)

6. Piracy, aggravated by endangering the life of any person on board any vessel in the realm, in respect of which the piracy is committed. 
(7 Wm. IV. & 1 Vict. c. 88. s. 4.)

7. Setting fire to a dwelling-house, any person being therein. 
(7 Wm. IV. & 1 Vict. c. 89. s. 4.)

8. Destroying vessels with intent to murder, or whereby human life is endangered. 
(7 Wm. IV. & 1 Vict. c. 89. s. 4.)

9. Exhibiting false lights, &c. with intent to bring ships into danger, or unlawfully doing anything tending to the destruction of ships in distress. 
(7 Wm. IV. & 1 Vict. c. 89. s. 5.)

10. Besides the above offences, that of willfully and without lawful authority taking, carrying off or stealing any sort of goods, wares or merchandise, or any other thing used in pursuance of any Act relating to any duties on gold or silver plate made or wrought in Great Britain, for the purpose of marking or stamping such plate, appears to be still punishable with death.

That offence is contained in 55 Geo. III. c. 185. s. 7, by virtue of which enactment it was formerly also a capital crime to forge or utter the stamps provided for marking any such plate, or to fraudulently remove such stamps from one piece of such plate to another, or privately and secretly to use such stamps with intent to defraud the king. The punishment of death for these last-mentioned offences was repealed, however, by 11 Geo. IV. & 1 Wm. IV. c. 66. s. 1 (as to the forging and uttering), and by 4 & 5 Vict. c. 56. s. 1 (as to the removing and fraudulently using); but by some inadvertence (for it is clear that it can never have been intended) the offence of being possessed, without lawful excuse, of forged stamps for marking gold or silver plate (the least criminal of all the acts specified in 55 Geo. III. c. 185. s. 7) is still left capital.

There are two other enactments of capital offences, which also do not appear to have been repealed. The 2 Geo. II. c. 25. s. 2, and the 12 Geo. III. c. 48. s. 1, make it capital for offenders convicted under the provisions of those statutes, to escape or break out of prison; and these enactments do not seem to have been wholly repealed, either expressly or by implication. The Criminal Law Commissioners (7th Report) say, 'Although many Acts have been passed which punish prison-break by penalties not capital, yet these seem to be confined to particular goals and prisons, and not to
affect the general enactments above referred to, as regards officers against their provisions confined in other prisons."

(Non-Capital.)

- Non-capital felonies are punishable as follows, viz., with
  I. Transportation for life, and previously thereto imprisonment
  or without hard labour, for any term not exceeding
  four years.
  1. Offenders transported from Great Britain being found at
  large, unless some lawful excuse, before the expiration of
  their term of transportation. (2 Geo. IV. c. 84, s. 39; &c.
  & 5 Wm. IV. c. 67.)
  II. Transportation for life.
  1. Rape. (9 Geo. IV. c. 31, s. 16; & 4 & 5 Vict. c. 56, s. 3.)
  2. Carnally knowing and abusing girls under ten years of
  age. (9 Geo. IV. c. 31, s. 17; & 4 & 5 Vict. c. 56, s. 3.)
  III. Transportation for life, or not less than fifteen years,
  or imprisonment for any term not exceeding three years, with
  or without hard labour or solitary confinement, or with both.
  1. Piracy. (28 Hmn. VIII. c. 15; 11 & 12 Wm. III. c. 7,
  s. 8, & 10; 4 Geo. I. c. 11, s. 7; 6 Geo. I. c. 10; 8
  Geo. I. c. 54, ss. 1 & 3; 2 Geo. II. c. 26, s. 7; 18 Geo.
  II. c. 48, s. 3.)
  2. Offences against the Riot Act.* (1 Geo. I. st. 2, c. 5,
  ss. 1 & 5; 7 Wm. IV. & 1 Vict. c. 91, ss. 1 & 2.)
  3. Resucing a murderer out of prison, or whilst going to or
  from such execution. (Geo. II. c. 97, s. 7; 7 Wm. IV. & 1
  Vict. c. 91, ss. 1 & 2.)
  4. Seducing sailors or soldiers from their allegiance, or
  trust to them mutiny. (37 Geo. III. c. 70, s. 1; & 57 Geo.
  III. c. 73, s. 1; 2 Geo. IV. c. 56, ss. 1 & 2.)
  5. Administering oaths binding any person to commit
  treason or any capital felony. (29 Geo. III. c. 104, s. 1; &
  7 Wm. IV. & 1 Vict. c. 91, ss. 1 & 2.)
  6. Any subject of her majesty, or any person residing in
  any of the queen's dominions, or in any place under
  the government of the East India Company, or upon the high
  seas, or within the Admiralty jurisdiction, being away &c.
  persons to make slaves of them. (2 Geo. IV. c. 113, s. 9; 3
  & 4 Wm. IV. c. 73; 7 Wm. IV. & 1 Vict. c. 91, ss. 1 & 2.)
  7. Assembling armed, to the number of three or more, for
  the purposes of smuggling. (7 Wm. IV. & 1 Vict. c. 91, ss.
  1 & 2; 8 & 9 Vict. c. 87, s. 63.)
  8. Shooting at vessels belonging to the navy or in the
  revenue service, within 100 leagues of the coast; or shooting at
  rear-ends tugs and prizes employed for the prevention of
  smuggling. (7 Wm. IV. & 1 Vict. c. 91, ss. 1 & 2; 8 & 9
  Vict. c. 87, s. 64.)
  9. Attempts to hinder, by attempting to administer poison,
  or shooting at or attempting to drown, strangle, or strike
  any person, although no bodily injury be effected. (7
  Wm. IV. & 1 Vict. c. 85, ss. 3 & 8.)
  10. Shooting at or attempting to discharge any kind of
  loaded arms at or wounding any person, with intent to do
  grievous bodily harm to such person, or to prevent lawful
  apprehension or detention. (7 Wm. IV. & 1 Vict. c. 85, ss.
  4 & 8.)
  11. Sending explosive substances, &c. to any person, or
  throwing any corrosive fluid or other destructive matter upon
  any person, with intent to do grievous bodily harm, and
  whereby grievous bodily harm is done to any person. (7
  Wm. IV. & 1 Vict. c. 85, ss. 5 & 9.)
  12. Attempting to procure the miscarriage of women. (7
  Wm. IV. & 1 Vict. c. 85, ss. 6 & 8.)
  13. Robbery, aggravated by the offender being armed, by
  means of, or by the use of personal violence to the person
  robbed. (7 Wm. IV. & 1 Vict. c. 87, ss. 3 & 10.)
  14. Extorting property by threatening to accuse
  whereof any money or other property. (7 Wm. IV. & 1
  Vict. c. 87, ss. 4. & 8.)
  15. Setting fire to places of worship or houses, or to
  buildings or erections used for the purposes of trade, with
  intent to injure or defraud any person. (7 Wm. IV. & 1
  Vict. c. 89, ss. 4 & 8.)
  16. Setting fire to or otherwise destroying vessels, with
  intent to prejudice any person interested therein or in the goods
  on board the same, as an owner, partner or underwriter. (7
  Wm. IV. & 1 Vict. c. 89, ss. 6 & 12.)
  17. Forcibly preventing a person endeavouring to save his
  life from a vessel in distress or wrecked. (7 Wm. IV. &
  1 Vict. c. 89, ss. 7 & 12.)
  18. Setting fire to coal-mines. (7 Wm. IV. & 1 Vict.
  c. 89, ss. 9 & 12.)
  19. Setting fire to stacks of corn, grain, coal or wood, &c.,
  or to any stook of wood. (7 Wm. IV. & 1 Vict. c. 89, ss.
  10 & 12.)
  IV. Transportation for life, or not less than fifteen years,
  or imprisonment for any term not exceeding three years, with
  or without hard labour or solitary confinement, or with both.
  1. Burglary. (7 Wm. IV. & 1 Vict. c. 86, ss. 3 & 7.)
  VI. Transportation for life, or not less than seven years.
  1. Personating soldiers or other persons entitled to prize-
  money, &c. on account of military services, or their
  representatives; or
  2. Forging the name or handwriting of any person so
  entitled, or of any officer or servant of Chelsea Hospital, or
  any writing concerning the payment of any such prize-money, &c.
  (2 Wm. IV. c. 53, s. 49.)
  VII. Transportation for life, or for any term of years.
  1. Taking on board any person (two or more, or committed thereto) binding the person taking the same to commit treason or any capital felony. (39 Geo. III. c. 104, s. 1.)
  2. Personating soldiers or other persons entitled to
  pensions, &c. on account of military services, or their
  representatives; or
  3. Forging the name or handwriting of any person so
  entitled, or of any officer or servant of Chelsea Hospital, or
  any writing concerning the payment of any such pensions, &c.
  (7 Geo. IV. c. 16, s. 38.)
  VIII. Transportation for life, or for fourteen or seven years.
  1. Aiding the escape of prisoners of war from prison or
  from the queen's dominions, if at large upon parole. (26
  Geo. III. c. 156, s. 1.)
  2. Subjects of her majesty aiding, upon the high seas, the
  escape of prisoners of war after they have quitted the coast.
  (26 Geo. III. c. 156, s. 3.)
  IX. Transportation for life, or not less than seven years, or
  imprisonment for any term not exceeding seven years, with
  or without hard labour.
  1. Stealing or embezling her majesty's ammunition, naval
  or military stores. (4 Geo. IV. c. 53; 7 & 8 Geo. IV. c.
  27.)
  2. Sending letters threatening to kill any person, or to
  burn his house, stocks, &c.: or rescuing a person in custody
  for any such offence. (4 Geo. IV. c. 54, s. 3; 7 & 8 Geo. IV.
  c. 27.)
  3. Bankrupt not surrendering, or not discovering all his
  estate, or embezling or concealing any part thereof to the amount
  of 10L or upwards, &c. (5 & 6 Vict. c. 122, ss. 32 and
  83.)
  X. Transportation for life, or not less than seven years, or
  imprisonment for any term not exceeding four nor less than
  two years, with or without hard labour or solitary confine-
  ment, or with both.
  1. Forgery of the seal or bonds of the South Sea Company
  (4 Geo. I. c. 4, s. 56; 11 Geo. IV. & 1 Wm. IV. c. 66,
  ss. 1 & 26); of receipts or warrants of the South Sea
  Company (6 Geo. I. c. 11, s. 50; 11 Geo. IV. & 1 Wm.
  IV. c. 66, s. 4; &c. 2 Geo. IV. c. 129, s. 4; 7 Geo. IV.
  c. 64, s; 7 Wm. IV. & 1 Vict. c. 84, ss. 2 & 3); of
  seals, policies, &c. of the London and Royal Exchange
  Assurance Companies (4 Geo. I. c. 18, s. 15; 11 Geo. IV.
  & 1 Wm. IV. c. 66, s. 1); certain Army Orders made forth
  in pursuance of 6 Geo. I. c. 11 & 17, 7 Geo. I. st. 1, c.
  30, 8 Geo. I. c. 20, or 9 Geo. I. c. 12, or of any authority
  to transfer the same (9 Geo. I. c. 12, s. 4; 11 Geo. IV. &
  1 Wm. IV. c. 64, s. 26); of the name or handwriting of
  the Accountant-General, Registrar, or Clerk of the Report
  Office (of the Court of Chancery), or of any cashier of the
  Bank, to any instrument relating to the sufferers' money
effects (12 Geo. I. c. 32, s. 9; 11 Geo. IV. & 1 WM. IV. c. 66, ss. 1, 26, and 31); of Mediterranean fisheries (4 Geo. II. c. 18, s. 1; 11 Geo. IV. & 1 WM. IV. c. 66, ss. 1 and 26); of the common seal, bonds, &c, of the English Linen Company (11 Geo. III. c. 120, ss. 17; 11 Geo. III. c. 66, ss. 1 and 26); of certificates, &c, of the Commissioners for the Reduction of the National Debt (32 Geo. III. c. 55, ss. 9; 11 Geo. IV. & 1 WM. IV. c. 66, ss. 4, 2 & 3 WM. IV. c. 123; 3 & 4 WM. IV. c. 64, ss. 3; 7 WM. IV. & 1 Vict. c. 84, ss. 2 and 3); of the seal, policies, &c, of the Globe Insurance Company (39 Geo. III. c. 88, s. 22; 11 Geo. IV. & 1 WM. IV. c. 66, ss. 1 and 26); of the name or handwriting of the Treasurer of the Ordnance, &c, to any appointment, &c, on the Bank (46 Geo. IV. c. 45, s. 9; 11 Geo. IV. & 1 WM. IV. c. 66, ss. 4, 2 & 3 WM. IV. c. 123; 3 & 4 WM. IV. c. 44, s. 3; 7 WM. IV. & 1 Vict. c. 84, ss. 2 and 3); of the name or handwriting of the Receiver-General of Stamps and Taxes, or of his clerk, or of the Commissioners of Stamps and Taxes, to any draft, &c, on the Bank (46 Geo. III. c. 76, ss. 9; 11 Geo. IV. & 1 WM. IV. c. 66, ss. 4, 2 & 3 WM. IV. c. 123; 3 & 4 WM. IV. c. 44, s. 3; 7 WM. IV. & 1 Vict. c. 84, ss. 2 and 3); of certificates of the issue of Exchequer-bills for carrying on public works and fisheries in the United Kingdom (57 Geo. III. c. 34, ss. 9; 3 Geo. IV. c. 86, ss. 54; 11 Geo. IV. & 1 WM. IV. c. 66, ss. 1 and 26); of the name or handwriting of the Accountant-General, Barons, or Clerk of the Reports (of the Court of Exchequer), or of any cashier of the Bank, on any instrument relating to the agents' money or effects (11 Geo. IV. c. 113, s. 23; 11 Geo. IV. & 1 WM. IV. c. 66, ss. 1 and 26); of the name or handwriting of the Accountant-General, Barons, or Clerk of the Reports (of the Court of Exchequer), or of any cashier of the Bank, on any instrument relating to the agents' money or effects (11 Geo. IV. c. 113, s. 23; 11 Geo. IV. & 1 WM. IV. c. 66, ss. 1 and 26); of the name or handwriting of the Receiver-General of Stamps and Taxes, or of any appointment, &c, on the Bank (46 Geo. IV. c. 45, s. 9; 11 Geo. IV. & 1 WM. IV. c. 66, ss. 4, 2 & 3 WM. IV. c. 123; 3 & 4 WM. IV. c. 44, s. 3; 7 WM. IV. & 1 Vict. c. 84, ss. 2 and 3); of certificates or appointments relating to public salaries, pensions, and allowances (3 Geo. IV. c. 113, s. 23; 11 Geo. IV. & 1 WM. IV. c. 66, ss. 1 and 26); of certificates of certain stock, transferable at the Banks of England and Ireland respectively (5 Geo. IV. c. 53, s. 22; 11 Geo. IV. & 1 WM. IV. c. 66, ss. 1 and 26); of the name or handwriting of the receiver-general of Exchequer, or Exchequer comptroller, &c, on any instrument relating to the agents' money or effects (11 Geo. IV. c. 53, s. 55; 11 Geo. IV. & 1 WM. IV. c. 66, ss. 4, 2 & 3 WM. IV. c. 123; 3 & 4 WM. IV. c. 44, s. 3; 7 WM. IV. & 1 Vict. c. 84, ss. 2 and 3); of stamps upon or relating to cheques or chequer-bills (51 Geo. IV. & 1 WM. IV. c. 66, ss. 1 and 26); of certificates, &c, as to annuities granted by the commissioners for the reduction of the national debt, or of instruments made by them relating thereto (10 Geo. IV. c. 24, s. 41; 7 WM. IV. c. 66, ss. 1 and 26; 2 & 3 WM. IV. c. 56, s. 19; 7 WM. IV. & 1 Vict. c. 84, ss. 1 and 3); of certificates and other documents in order to obtain pay or prince-money, due in respect of services performed by any person in the navy (11 Geo. IV. & 1 WM. IV. c. 20, ss. 85 and 88; 2 WM. IV. c. 40, s. 85); of Exchequer-bills, &c, Exchequer debentures, East-India bonds, &c.

As to the forgery of stamps on newspapers, the 8th & 9th WM. IV. c. 76, s. 1, appears to make that offence punishable under 10 Geo. III. c. 184, s. 4, in the case of the forgery of stamps on a newspaper, or newspaper-plate, or newspaper-paper, (see Lonsdale's 'Statute Criminal Law,' p. 81, note (c); the language of the Act, however, is not clear.)

The 59 Geo. III. c. 143, s. 10, appears to be repealed, so far as relates to the Customs, by 6 Geo. IV. c. 130, s. 2, by which the authority to stamp such documents is vested in the Commissioners of Customs; and by 10 Geo. IV. c. 56, s. 2, also, as to certificates relating to the duties of Excise, see 41 Geo. III. (U.S.) c. 61, s. 1.

1 See also 37 Geo. III. c. 141; 4 Geo. IV. c. 69 and 81 & 93 Geo. IV. c. 46, ss. 3, 4; 11 Geo. IV. & 1 WM. IV. c. 27; 7 Geo. IV. c. 19; 47 & 48 Geo. IV. c. 12; 7 WM. IV. & 1 Vict. c. 84; 8 Geo. IV. c. 117; 1 & 2 WM. IV. c. 51; 3 & 4 WM. IV. c. 84; 1 & 2 Vict. c. 140; and 3 & 4 Vict. c. 69, s. 14.

As to whether the forgery of Exchequer-bills, made out in pursuance of the same or similar orders, and before standing the stamp of that pardon in case of the forgery of other Exchequer-bills, was an offence punishable by imprisonment for two years, and the offender to find sureties for good behaviour for two years more, or to be compaigned from the court of King's Bench for a first offence, and for a first offence, to be sent to the house of correction, and for a second or subsequent offence, to be sent to the house of correction for a term not less than six months, and the offender to find sureties for good behaviour for one year more, see 13 Geo. IV. c. 56, s. 1, and the Exchequer-bills directed to be computed from the end of the law six months. (37 Geo. III. c. 146, s. 4.)
10. Privately or publicly using stamps provided in pursuance of any Stamp Act, with intent to defraud her Majesty of any duties granted by such act. (29 Geo. III. c. 184, s. 7; 56 Geo. III. c. 185, s. 33; & 5 Vict. c. 56, ss. 1 and 4.)

11. Buying, selling, or offering to remove or offering stamps from vellum, parchment, paper, gold or silver plate, &c., with intent to use them again. (55 Geo. III. c. 184, s. 7; c. 185, s. 7; & 4 & 6 Vict. c. 56, ss. 1 and 4.)

12. Transporting from St. Helena into England before the expiration of their term of transportation. (6 Geo. IV. c. 85, ss. 18; 4 & 5 Vict. c. 56, ss. 1 and 4.)

13. Riotously destroying places of worship or houses, or buildings used for the business of mines, &c. (7 & 8 Geo. IV. c. 3w, s. 8; & 4 & 5 Vict. c. 56, ss. 1 and 4; & 6 & 7 Vict. c. 10.)

XII. Transportation for life or not less than seven years, or imprisonment for any term not exceeding four nor less than two years. Being possessed, without lawful excuse, of forged dies, &c., or of any vellum parchment, or other thing having thereon the impression of any forged die, &c.; or fraudulently using any stamp which shall have been removed from any other vellum, &c.; or getting out of or from any vellum, &c., any thing having thereon the impression, with intent to use the stamp then being thereon, for any instrument or thing liable to stamp duty, &c. (3 & 4 Wm. IV. c. 97, ss. 11 and 12; & 4 & 5 Wm. IV. c. 60.)

14. Forgery of any stamped or private or fraudulently using such stamps, or, without lawful excuse, being possessed of any paper or other material so privately or fraudulently stamped. (7 & 4 Vict. c. 96, s. 22.)

XIII. Transportation for life or not less than seven years, or imprisonment for any term not exceeding four years, with or without hard labour or solitary confinement, or with both; and the offender, if a male, may be once, twice, or thrice publicly or privately whipped, in addition to such imprisonment. Sending threatening letters with intent to extort money, &c. (7 & 8 Geo. IV. c. 39, ss. 4 and 8.)

15. Destroying, cutting, or defacing any stamp, with intent to help to property which has been stolen, &c. (unless the person so taking such reward cause the offender to be apprehended and tried for the same.) (7 & 8 Geo. IV. c. 29, ss. 4 and 58.)

16. Forgery or damaging goods of silk, woolen, linen, or cotton, &c., whilst in progress of manufacture, or of any machine or implement used therein, or forcibly entering any place to commit any of those offences. (7 & 8 Geo. IV. c. 30, ss. 3 and 27.)

17. Breaking down sea-banks, &c., whereby any land shall be in danger of being overflowed or damaged; or destroying works on navigable rivers or canals. (7 & 8 Geo. IV. c. 39, ss. 27.)

18. Destroying, &c., public bridges. (7 & 8 Geo. IV. c. 30, ss. 13 and 27.)

XIV. Transportation for life or not less than seven years, or imprisonment not exceeding four years, with or without hard labour or solitary confinement, or with both. Counterfeiting the queen's current gold or silver coin. (2 Wm. IV. c. 54, ss. 3 and 19.)

Gilding or silvering or colouring counterfeit coin, or any pieces of metal, with intent to make them pass for the queen's current gold or silver coin; or colouring or altering genuine coin, with intent to make it pass for a higher coin. (2 Wm. IV. c. 54, ss. 4 and 19.)

Buying, &c., or putting off, &c., at a lower value than the same by its denomination imports, or importing into the kingdom the same or counterfeit coin, or passing the queen's current gold or silver coin, knowing the same to be counterfeit. (2 Wm. IV. c. 84, ss. 6 and 19.)

4. Having been convicted of uttering counterfeit coin intended to pass for the queen's current gold or silver coin; or having been convicted of uttering such coin, and being possessed at the time of such uttering of more such coin, or having, on the same day or within ten days afterwards, uttered more such coin, or having falsely passed any of such offences. (2 Wm. IV. c. 84, ss. 7 and 19.)

5. Having been convicted of having possession of three or more pieces of counterfeit coin intended to pass for the queen's current gold or silver coin, with intent to utter the same, afterwards committing the like offence. (2 Wm. IV. c. 54, ss. 8 in part and 19.)

6. Without lawful authority, making, having or dealing in, or having in possession, or using, any instrument adapted for counterfeiting the queen's current gold or silver coin. (2 Wm. IV. c. 34, ss. 10 and 19.)

7. Without lawful authority, conveying out of the Mint instruments of coining, or any coin, bullion, &c. (2 Wm. IV. c. 34, ss. 11 and 19.)

8. Persons employed under the Post Office stealing, embezailing, secreting, or destroying post letters containing money, &c. (7 & 8 Geo. IV. c. 31, s. 8.)

10. Stealing post letters, or post letters from post offices, or from the officers of the post office, or from mailboxes; or stopping mail with intent to rob or search them. (7 Wm. IV. & 1 Vict. c. 36, ss. 27, 41, 42.)

11. Receiving letters or other property stolen, &c. (2 Wm. IV. c. 34, ss. 11 and 19.)

12. Forgery of the name or handwriting of the Receiver-General of the General Post-office, &c. to any draft &c. on the Bank. (7 Wm. IV. & 1 Vict. c. 36, ss. 33, 41, 42.)

XIV. Transportation for life or not less than seven years, or imprisonment for any term not exceeding four years, with or without hard labour.

1. Taking away or detaining, from motives of lucre, an heirless, &c. against her will, with intent to marry or defile her, &c. (9 Geo. IV. c. 51, s. 19.)

XV. Transportation for life or not less than seven years, or imprisonment for any term not exceeding four years, with or without hard labour; or such fine as the court shall award. (9 Manauafigh, &c. 36, ss. 19.)

XVI. Transportation for life or not less than seven years, or imprisonment for any term not exceeding four years.

1. Persons employed in the Public Record Office certifying as true false legal or copies of records in the hand of the Master of the Rolls. (1 & 2 Vict. c. 94, s. 19 in part.)

2. Forgery of the signature of any Assistant Record Keeper, for the purpose of counterfeiting a certified copy of a record, or of the Seal of the Public Record Office. (1 & 2 Vict. c. 94, s. 19 in part.)

XVII. Transportation for life or not less than seven years, or imprisonment for any term not exceeding three years, with or without hard labour or solitary confinement, or with both.

1. Stealing in a dwelling-house at the value of 5s. or more. (7 & 8 Geo. IV. c. 29, s. 12; 2 & 3 Wm. IV. c. 82; & 4 & 5 Wm. IV. c. 44, s. 3; 7 Wm. IV. & 1 Vict. c. 90, ss. 1 and 2.)

2. Breaking, entering and stealing in a dwelling-house to any value. (7 & 8 Geo. IV. c. 29, ss. 12; 3 & 4 Wm. IV. c. 154, s. 2; 7 Wm. IV. & 1 Vict. c. 90, ss. 1 and 2.)

3. Castle-stealing or killing-cattle, with intent to steal the carcass or skin or any part of the cattle so killed. (7 & 8 Geo. IV. c. 29, s. 25; 2 & 3 Wm. IV. c. 62; & 3 & 4 Wm. IV. c. 44, s. 3; 7 Wm. IV. & 1 Vict. c. 90, ss. 1 and 2.)

4. Breaking, entering and stealing in buildings within the curtilage of a dwelling-house, but having no communication with the dwelling-house, either immediately or by means of a covered and independent passage, from the one to the other. (7 & 8 Geo. IV. c. 29, ss. 13 and 14; 7 Wm. IV. & 1 Vict. c. 90, ss. 2 and 3.)

5. Breaking, entering and stealing in shops, warehouses or counting-houses. (7 & 8 Geo. IV. c. 29, ss. 15; 7 Wm. IV. & 1 Vict. c. 90, ss. 2 and 3.)

* The punishment for uttering, in respect of a first offence, is imprisonment not exceeding one year, with or without hard labour or solitary confinement, or with both.

† For the purpose of this and the next offence no building, although within the curtilage of a dwelling-house, will be deemed to be such dwelling-house, unless it is a building between which and the dwelling-house there is no communication, either immediate or by means of a covered and independent passage, from the one to the other.

‡ See below, the punishment for a first offence.
5. Stealing to the value of 10s. goods of silk, woollen, linen or cotton, &c., whilst exposed in any place during any stage of manufacture. (7 & 8 Geo. IV. c. 29 ss. 16; 7 Wm. IV. & 1 Vict. c. 90 ss. 2 and 3.)

6. Stealing goods, from vessels, &c., in ports or upon navigable rivers, canals, docks, sheds, workshops, warehouses, or magazines, &c., adjoining thereto. (7 & 8 Geo. IV. c. 29, ss. 17; 7 Wm. IV. & 1 Vict. c. 90 ss. 2 and 3.)

7. Maliciously killing, maiming or wounding cattle. (7 & 8 Geo. IV. c. 30, ss. 16; 7 Wm. IV. & 1 Vict. c. 90 ss. 2 and 3.)

8. Maliciously destroying hop-binds growing on poles in hop plantations. (7 & 8 Geo. IV. c. 30, ss. 18; 7 Wm. IV. & 1 Vict. c. 90 ss. 2 and 3.)

9. Stealing in a dwelling-house, &c., and by threats or menace putting any inmate in bodily fear. (7 Wm. IV. & 1 Vict. c. 87 ss. 5 and 7.)

10. Robbery or stealing from the person. (7 Wm. IV. & 1 Vict. c. 96, ss. 5 and 10.)

11. Plundering vessels in distress, or wrecked, stranded, or cast on shore, or anything belonging to any such vessel. (7 Wm. IV. & 1 Vict. c. 87, ss. 8 and 10.)

12. Maliciously destroying any part of a vessel in distress, or wrecked, stranded or cast on shore, or anything belonging to such vessel. (7 Wm. IV. & 1 Vict. c. 89, ss. 9 and 12.)

13. Receiving, converting, &c., stolen goods, &c., with intent to defraud. (7 & 8 Geo. IV. c. 29 ss. 12 and 28.)

14. Without the authority of the Bank, making or being possessed of making, or attempting to make, any bank-notes, &c. (7 & 8 Geo. IV. c. 29 ss. 13.)

15. Without the authority of the Bank, engraving, making or using instruments for making, &c., bank-notes, &c., or any character or ornament resembling any part of a bank-note, &c. (11 Geo. IV. & 1 Wm. IV. c. 66, ss. 15 and 16.)

16. XXI. Transportation for any term not exceeding fourteen years.

17. Aiding prisoners to escape, or in attempting to escape from prison, whether an actual escape be made or not. (4 Geo. IV. c. 64, ss. 43.)

18. Rescuing offenders sentenced to be transported or banished. (5 Geo. IV. c. 84, ss. 22.)

20. Forging, &c., of the queen's mark on silver or gold, or of any false or counterfeit coin or bullion. (7 & 8 Geo. IV. c. 29, ss. 4 and 54.)

21. Boatmen and others concealing, &c., or not reporting according, &c, in obstructing the officers, &c., or any other articles found by them on the coast, &c. (7 & 8 Geo. IV. c. 29 ss. 4 and 54.)

22. Bailment and others concealing, &c., or not reporting according, &c., in obstructing the officers, &c., or any other articles found by them on the coast, &c. (7 & 8 Geo. IV. c. 29 ss. 4 and 54.)

23. Transporting for any term not exceeding fourteen nor less than seven years, or imprisonment not exceeding three years, with or without hard labour or solitary confinement, or with both. (1 & 2 Geo. IV. c. 75 s. 1; and c. 76.)

24. XXI. Transportation for any term not exceeding fourteen nor less than seven years, or imprisonment not exceeding three years, with or without hard labour, &c., or with both. (1 & 2 Geo. IV. c. 75, ss. 5 and 19.)

25. XXV. Transportation for any term not exceeding fourteen or confinement not exceeding five nor less than three years, with hard labour. (2 Wm. IV. & 1 Vict. c. 36 ss. 41 and 42.)

26. XXVI. Transportation for any term not exceeding fourteen years, or confinement not exceeding five years, or imprisonment not exceeding three years, with or without hard labour, &c., or with both. (2 Wm. IV. & 1 Vict. c. 36, ss. 41 and 42.)

27. Providing false affidavits, &c., in order to procure any person to be admitted as pensioner as the widow of an officer of the royal navy, &c. (11 Geo. IV. & 1 Wm. IV. c. 20, ss. 87 in part and 88.)

28. Bribing or enticing a person to escape from prison. (11 Geo. IV. & 1 Wm. IV. c. 20, ss. 86 and 88; 2 Wm. IV. c. 40.)

29. Aiding prisoners to escape, or in attempting to escape from prison, &c. (11 Geo. IV. & 1 Wm. IV. c. 20, ss. 86 and 88; 2 Wm. IV. c. 40.)

30. Making false affidavits, &c., in order to procure any person to be admitted as pensioner as the widow of an officer of the royal navy, &c. (11 Geo. IV. & 1 Wm. IV. c. 20, ss. 87 in part and 88.)

31. Impersonating a public officer. (2 Wm. IV. c. 4, s. 1.)

32. Forgery, &c., of marks on silver or gold, or of any marks of value. (7 & 8 Geo. IV. c. 22, s. 2.)

33. Forger, &c., of or disposing of any marks on silver or gold. (7 & 8 Geo. IV. c. 22, s. 2.)

34. Forger, &c., of marks on silver or gold or of any marks of value. (7 & 8 Geo. IV. c. 22, s. 2.)

35. XXIII. Transportation for any term not exceeding fourteen nor less than seven years, or imprisonment not exceeding three years, with or without hard labour or solitary confinement, or with both.

36. XXIV. Transportation for any term not exceeding fourteen nor less than seven years, or imprisonment not exceeding three years, with or without hard labour, solitary confinement, or with both.

37. XXV. Transportation for any term not exceeding fourteen nor less than seven years, or imprisonment not exceeding three years, with or without hard labour, solitary confinement, or with both.

38. XXVI. Transportation for any term not exceeding fourteen years, or confinement not exceeding five nor less than three years, with hard labour.
LAW

XXIX. **Transportation for seven years.**

1. By forcibly inducing persons, &c. within the hamlet of Wapping, Stepney, or any other place within the limits of the weekly bills of mortality, wherein persons shall unlawfully assemble and associate for the sheltering themselves from their debters, or on which complaint shall have been made by a presentment of the grand jury at a general or quarter sessions of the proper county. (11 Geo. I. c. 22, ss. 1 and 2.)

2. Aiding the escape from officers of justice of prisoners in their custody for the purpose of being carried to gaol by virtue of a warrant of commitment for treason or felony, or the escape of felons on their way for transportation. (16 Geo. II. c. 1, s. 1.)

3. Riotously assembling, to the number of five or more, to rescue offenders against the Acts relating to spirituous liquors; or assaulting persons who have given, &c. evidence, &c. against such offenders, &c. (24 Geo. II. c. 40, s. 28.)

4. Prisoners for debt not delivering in under the Lords' Act a true account of all their estate and effects, &c.† (32 Geo. III. c. 28, s. 17; 83 Geo. III. c. 5; 39 Geo. III. c. 50.)

5. Damaging, &c. buoys, &c. fixed to the anchors or moorings of vessels in the Thames, with intent to steal the same. (32 Geo. III. c. 28, s. 13.)

6. Being convicted a second time of unlawfully stopping or attempting to stop, or of otherwise preventing the conveyance of grain to or from any city, market-town or place of sending or receiving grain. (11 Geo. II. c. 29; 36 Geo. III. c. 9, ss. 2 and 6.)

7. With intent to prevent the removal of grain, pulling down or otherwise destroying granaries, &c. (30 Geo. III. c. 2.)

8. Forgery of the declarations of the return of premiums on policies or contracts of insurance. (54 Geo. III. c. 133, s. 10; 54 Geo. III. c. 144, s. 11.)

9. Forcibly rescuing offenders or goods seized under 6 Geo. IV. c. 80 (for repealing the duties on spirits distilled in England, &c.), or otherwise forcibly opposing the execution of the powers of that Act. (6 Geo. IV. c. 80, s. 143.)

10. Forgery of documents within the time exceeding forty years with smuggling goods, or in company with only one person within five miles of the coast, &c. &c. (4 Geo. IV. c. 87, s. 65.)

11. Forgery of the superscription of a post letter with intent to avoid the payment of postage.§ (7 Wm. IV. and 1 Vict. c. 36, s. 34.)

XXX. **Transportation for any term not exceeding seven years.**

1. Forgery of the seal, &c. of the British Society for extending the Fisheries and Improving the Sea Coasts of the Kingdom of France. (105 & 106 Geo. III. c. 25, s. 1.)

2. Administering oaths intended to bind the person taking the same to engage in any sedulous purpose, &c. &c., or to be of any association or confederacy formed for any such purpose, &c. (105 & 106 Geo. III. c. 25, s. 2.)

3. Counterfeiting foreign gold or silver coin, not permitted to be current within the realm. (37 Geo. III. c. 126, s. 2.)

4. Bringing any such coin into the realm with intent to utter the same. (37 Geo. III. c. 126, s. 3.)

5. Boxmen, &c. conveying annals, &c. which they know to have been swept for or otherwise taken possession of without being reported according to law, to any foreign ports, &c. and there disposing of the same. (1 & 2 Geo. IV. c. 75, s. 15.)

XXI. **Transportation for seven years, or imprisonment for any term not exceeding two years.**

1. Without lawful excuse, making or being possessed of any instrument for making the paper used for permits by the Commissioners of Excise, or being possessed of any such paper, or engraving, &c. any plate, &c. for making or printing the paper used for permits, &c. (9 Wm. IV. c. 16, s. 3.)

2. Without lawful excuse, making or being possessed of instruments for making the paper to be used for postage covers, or being possessed of any such paper, or by any means initiating or causing to appear any post marks, &c. &c. to be used in postage covers. (3 & 4 Vict. c. 96, s. 29.)

XXXII. **Transportation for seven years, or imprisonment not exceeding four years.**

1. Forgery of certificates or bills of exchange mentioned in 2 & 3 Wm. IV. c. 106 (An Act for enabling Officers, &c. in the Army to draw for their Half-pay and Allowances). (2 & 3 Wm. IV. c. 106, s. 6.)

XXXIII. **Transportation for seven years, or imprisonment for any term not exceeding three years nor less than one year, with hard labour.**

1. Forgery of the seals, stamps or signatures of such certificates, official or public documents, proceedings of corporations, or joint stock or other companies, or certified copies of such documents or proceedings, as are receivable in evidence in Parliament, or in any judicial proceeding, or tendering in evidence such certificates, &c. with false or counterfeited seals &c. thereunto;

2. Forgery of the signature of any equity or common law judge of the Superior Courts at Westminster, to any judicial or official document, or tendering in evidence any such document with a false, &c. signature of any such judge thereto;

3. Printing copies of private acts or of the journals of either House of Parliament, whose common seal or signet has been printed by the printers to the Crown or either House of Parliament, or tendering in evidence any such copy, knowing that the same was not printed by the persons by whom it so purports to have been printed. (9 & 10 Vict. c. 113, s. 4.)

XXXIV. **Transportation for seven years, or imprisonment for any term not exceeding three years, with or without hard labour or solitary confinement, or with both.**

1. Persons employed under the Post-Office stealing, embezzling, secreting or destroying post-letter. (7 Wm. IV. & 1 Vict. c. 30, ss. 20 and 48.)

XXXV. **Transportation for seven years, or imprisonment for any term not exceeding two years nor less than one year, with or without hard labour or solitary confinement, or with both.**

1. Forgery of the name or handwriting of witnesses attesting the execution of powers of attorney to transfer any public stock transferable at the Bank or South Sea House, or any capital stock of any body corporate, &c. established by charter or act of parliament, or to receive any dividend in respect thereof (11 Geo. IV. & 1 Wm. IV. c. 66, ss. 8 and 26); or copies of registers of baptisms, marriages, or burials, directed by law to be transmitted to the Crown or either House of Parliament, not being made or being false entries in such copies, &c. (11 Geo. IV. & 1 Wm. IV. c. 66, ss. 22 and 26.)

2. Clerks, &c. of the Bank or South Sea House, with intent to defraud any person, making false entries in the books or registers of debts due, or in the books or registers of dividends making false entries in such entries, &c. (11 Geo. IV. & 1 Wm. IV. c. 66, ss. 9 and 26.)

XXXVI. **Transportation for seven years, or imprisonment for any term not exceeding two years, with or without hard labour or solitary confinement, or with both; and the offender, if a male, may be once, twice, or thrice publicly or privately whipped, in addition to such imprisonment.**

1. Forgery of the stamps or seals on hides or skins (9 Anne, c. 11; 10 Anne, c. 99; 5 Geo. I. c. 2, s. 9; 52 Geo. III. c. 143, s. 1; 7 & 8 Geo. IV. c. 28, ss. 8 and 9); of the stamps or seals used for marking strips for sealing casks or barrels, in pursuance of 4 Geo. III. c. 37, An Act for the better establishing a manufactory of Casks and Barrels at Wincle, in the County of Chester, &c. (4 Geo. III. c. 37, s. 26; 52 Geo. III. c. 143, s. 1; 7 & 8 Geo. IV. c. 28, s. 8 and 9; 1 Wm. IV. c. 17, s. 1) or of the stamps or seals, or the stamping of the seals or stamps or stamps of the Court of Admiralty or High Court of Appeal of Fries, &c., to any instrument relating to the money or effects of the suitors of those courts (53 Geo. IV. c. 161, s. 12; 7 & 8

* &c. see also 1 & 2 Geo. IV. c. 84, s. 1, which, under certain circumstances, inflict transportation for seven years, or imprisonment not exceeding three years.

† The first offence is punishable, on summary conviction, with imprisonment and labour for any term not exceeding three months nor less than one month.

§ There are still some cases to which this enactment is applicable.

As regards copies of registers of marriages, it would appear that this offence ceased to exist when the registers were removed to the department of the Registrar General, and marriage, in England, be committed with respect to such copies only as were transmitted hereafter to be filled in and entered into operation. It is still however, as regards registers of baptism or burial. (see 4th sect. of 6 & 7 Wm. IV. c. 46.)
Geo. IV. c. 29, ss. 8 and 9); of quarantine certificates (6 Geo. IV. c. 78, s. 25; 7 & 8 Geo. IV. c. 28, ss. 8 and 9); of the name or handwriting of her Majesty's Commissioners of Woods, Forests, Land Revenues, Works and Buildings, to any person for or in respect of any place, or any thing therein, or of such commissioners, &c. (7 & 8 Geo. IV. c. 28, ss. 8 and 9; 10 Geo. IV. c. 50, s. 124; & 3 Wm. IV. c. 1, s. 1); or of the process of informing courts of the recovery of debts and debts of the second instance, or of the execution of such determinations (7 & 8 Geo. IV. c. 28, ss. 8 and 9; & 7 & 8 Vict. c. 19, s. 5 in part).

2. Obstructing the execution of process, &c. within Suffolk Place or the Mint, in the parish of St. George, in the county of Surrey (7 & 8 Geo. I. c. 26, ss. 1 and 2; 7 & 8 Geo. IV. c. 28, ss. 8 and 9.)

3. Persons having preserved merchandise &c. belonging to vessels wrecked &c. within the jurisdiction of the Cinque Ports, selling or otherwise making away with the same, or in any manner altering the same with intent to prevent the discovery or identity thereof by the owners. (1 & 2 Geo. IV. c. 76, s. 8; 7 & 8 Geo. IV. c. 28, ss. 8 and 9.)

4. Quarantine officers deserting from their duty or permitting persons &c. to depart from liable to prosecution (7 & 8 Geo. IV. c. 28, ss. 8 and 9; 6 & 7 Wm. IV. c. 85, s. 30.).

5. Sodomising marriages (except in the case of Quakers or Jews, or by special licence) in any other place than a church or registered office, being so in any other place than the register of the district, &c. (7 & 8 Geo. IV. c. 28, ss. 8 and 9; 6 & 7 Wm. IV. c. 85, ss. 30.)

6. Superintendent registrars issuing certificates for marriage, or registering marriages, contrary to law; or registrars or superintendent registrars issuing licences for marriage, or sodomy marriages, contrary to law. (7 & 8 Geo. IV. c. 28, ss. 8 and 9; 6 & 7 Wm. IV. c. 85, s. 40; 7 Wm. IV. & 1 Vict. c. 22, s. 3.)

7. Destroying, counterfeit or inserting false entries in, the register-books directed to be performed by the act for registering births, deaths, and marriages in England; or forging the seal of the register-office. (7 & 8 Geo. IV. c. 28, ss. 8 and 9; & 6 & 7 Wm. IV. c. 85, s. 43.)

8. Officer of the court uttering false certificates of indictments and convictions of a previous felony; or any other person signing &c., such certificates as such officer, &c. (7 & 8 Geo. IV. c. 28, ss. 9 and 11.)

9. Simple larceny. (7 & 8 Geo. IV. c. 29, ss. 3 and 4.)

10. Deer-stealing, &c. where the deer are kept in enclosed lands. (7 & 8 Geo. IV. c. 29, ss. 3, 4, and 26.)

11. Deer-stealing, &c. where the deer are kept in enclosed lands (for a second offence*); or offending a second time, or in any other offence, in deer for which a pecuniary penalty only is imposed, whether such second offence be of the same description as the first or not. (7 & 8 Geo. IV. c. 29, ss. 3, 4, and 26.)

12. Officers heating or saving deer-keepers. (7 & 8 Geo. IV. c. 29, ss. 3, 4, and 29.)

13. Stealing oysters &c. from oyster-beds &c. (7 & 8 Geo. IV. c. 29, ss. 3, 4, and 36.)

14. Stealing or seiving with intent to steal, ore, coal &c. from mines &c. (7 & 8 Geo. IV. c. 29, ss. 3, 4, and 37.)

15. Stealing or damaging with intent to steal, or maliciously destroying &c. trees &c. growing in parks &c. or grounds belonging to dwelling-houses, if the value of the article stolen or the amount of injury done exceeds 11., or growing elsewhere, if such value or amount exceeds 8. (7 & 8 Geo. IV. c. 29, ss. 3, 4, and 38; and c. 30, ss. 19 and 27.)

16. Stealing, or damaging with intent to steal, or maliciously destroying &c. trees &c., wherever growing, if the stealing thereof, or the injury done is to the amount of a shifting at the least, and if the offender has been twice previously convicted.† (7 & 8 Geo. IV. c. 29, ss. 3, 4, and 39; and c. 30, ss. 20 and 27.)

17. Stealing, or damaging with intent to steal, or maliciously destroying &c. plants, vegetable products &c., growing in gardens, conservatories &c., if the offender has been

* The first offence is punishable on summary conviction only, by fine not exceeding 40. & 7 Wm. IV. c. 29, ss. 4, and 9.)

† The last two sections are convicts to be imprisoned for not exceeding twelve calendar months in addition to the punishment to which the offender was subject at the time of such attempt.
of debts or damages in personal actions, without lawful autho-
* 28 Geo. IV. c. 28, s. 8 and 9; 7 & 8 Vic. c. 15, s. 5 in part.*

32. Workmen in mines in Cornwall removing or concealing ore with intent to defraud the proprietors of such mines. (2 & 3 Geo. IV. c. 10, s. 10.)

XXXVII. Transportation for seven years, or imprisonment for any term not exceeding two years, with or without hard labour; and the offender, if a male, may be once, twice, or thrice publicly or privately whipped, in addition to such imprisonment.

1. Child-stealing. (9 Geo. IV. c. 51, s. 21.)

XXXVIII. Transportation for seven years, or imprisonment for any term not exceeding two years, with or without hard labour.

1. Bigamy. (9 Geo. IV. c. 81, s. 22.)

XXXIX. Transportation for any term not exceeding seven years, or imprisonment for any number of years.

1. Cutting away or in any way injuring or concealing buoy, &c. belonging to vessels or attached to the anchors or cables of vessels, whether in distress or otherwise. (1 & 2 Geo. IV. c. 76, s. 11.)

XL. Transportation for any term not exceeding seven years, or imprisonment not exceeding two years, with or without hard labour or solitary confinement, or with both.

1. Slaughtering or killing horses or other cattle without taking out the license and giving the notice required by the Act for regulating slaughtering-houses, or doing any act or thing within the hours limited by the Act, or not delaying to do so, when required by the Inspector. (20 Geo. III. c. 71, s. 8.)

IV. MISDEMEANOURS.

Misdemeanors are punishable as follows, viz. with:

I. Transportation for life.

1. Being at large within the United Kingdom after being sentenced to be banished under the provisions of the Roman Catholic Relief Act (10 Geo. IV. c. 7.), without any lawful excuse, after three calendar months from such sentence. (10 Geo. IV. c. 7, s. 36.)

II. Banishment for life.

1. Jews or ministers of Religious Orders or Societies of the Church of Rome, bound by monastic or religious vows, coming into the kingdom. (10 Geo. IV. c. 7, s. 29.); or

2. Having obtained the Secretary of State's licence to come into the United Kingdom within twenty days after being released from the time mentioned in such licence, &c. (10 Geo. IV. c. 7, s. 31.)

3. Within any part of the kingdom, becoming a Jew or minister of any Society of the Church of Rome bound by monastic or religious vows. (10 Geo. IV. c. 7, s. 84.)

III. Transportation for the term of fourteen years, or, in mitigation or commutation of such punishment, the offender to be publicly whipped, fined or imprisoned, or all or any one of more than.

1. Not being a contractor with the Commissioners of the Navy, Ordnance or Victualling Office for her Majesty's use, selling, receiving or being possessed of any warlike or naval, ordnance, victualising or other public stores, without being able to produce a certificate from the Commissioners of the Navy &c., expressing the occasion &c. of such stores being so in possession. (9 & 10 Wm. III. c. 41; 9 Geo. I. c. 8, s. 3; 39 Geo. III. c. 22.)

The I of Geo. IV. c. 76, s. 4, contains a similar provision as regards books &c. within the jurisdiction of the Cinque Ports, but subjects the offender to transportation not exceeding fourteen years.

This and the next two offenses do not apply to members of Female Societies (10 Geo. IV. c. 7, s. 37.)

39. 29 & 30 Geo. III. c. 89, s. 1, imposes the above penalties in respect of those offenses, by enacting that persons who commit them in the port of London, or having them there, or having them to have been stored, and shall, on being convicted thereof in due form of law, be transported, or, if the Judge shall think fit, to be severely whipped in public or privately, or in any other manner. The sentences of such persons are directed to be transported by the Queen's order and if the Judge shall think fit to mitigate or commute the punishment as above mentioned, the punishment of receivers law, however severe alone, whatever the Act 9 & 10 Geo. IV. c. 22, s. 34 and 35. Is there fore becomes a question how for such alteration has modified the above punishment.

40. Geo. III. c. 89, ss. 1 and 7; 54 Geo. III. c. 60; 55 Geo. III. c. 127; 56 Geo. III. c. 138, s. 2.

2. Being a second or even third time convicted (not being a contractor with the Commissioners of the Navy &c.) of being possessed of &c. certain of her Majesty's or other public stores, the being possessed of the same, which would not otherwise, as the first offence, subject a person to transportation. (9 & 10 Wm. III. c. 41: 39 & 40 Geo. III. c. 89, ss. 5 and 7; 54 Geo. III. c. 60; 55 Geo. III. c. 127; 56 Geo. III. c. 138, s. 2.)

IV. Transportation for any term not exceeding fourteen nor less than seven years, or fine or imprisonment, or both, such imprisonment to be with or without hard labour or solitary confinement, or with both.

1. Bankers, merchants &c. converting to their own use money or securities intrusted to them to be applied for a specified purpose. (7 & 8 Geo. IV. c. 29, ss. 4 and 48.)

2. Bankers, merchants &c. converting to their own use chattels, securities &c. intrusted to them for a special purpose, but without authority to sell or negotiate &c. the same. (7 & 8 Geo. IV. c. 29, ss. 4 and 48.)

3. Factors or agents pledging goods or merchandise intrusted to them for sale, as a security for money &c. borrowed &c. by them. (7 & 8 Geo. IV. c. 29, ss. 4 and 51.)

4. Transportation for any term not exceeding fourteen nor less than seven years, or imprisonment with hard labour for any term not exceeding three years.

1. Doing in any land, by sight, to the number of three or more (any of them armed), for the purpose of committing any theft or destroying game or rabbits. (9 Geo. IV. c. 69, s. 9.)

VII. Transportation for seven years.

1. Countertopping foreign copper or other coin of a less value than silver, not permitted to be current in this kingdom (for the second offence). (43 Geo. III. c. 159, s. 8.)

VIII. Transportation for seven years, or fine or imprisonment, or both, such imprisonment to be with or without hard labour or solitary confinement, or with both.

1. Stealing, obliterating or destroying records or original documents belonging to Courts of Record, &c. (7 & 8 Geo. IV. c. 29, ss. 4 and 21.)

2. Stealing, destroying or concealing wills or other testamentary instruments, either during the life of the testator or after his death. (7 & 8 Geo. IV. c. 29, ss. 4 and 22.)

3. Stealing title-deeds. (7 & 8 Geo. IV. c. 29, ss. 4 and 23.)

4. Obtaining property by false pretences. (7 & 8 Geo. IV. c. 29, ss. 4 and 53.)

IX. Transportation for seven years, or fine and imprisonment.

1. Forgery of permits, or knowingly accepting or receiving forged permits. (2 Wm. IV. c. 16, s. 4.)

X. Transportation for the term of fourteen years, or the like punishment as for a misdemeanor at common law.

1. Purchasing or receiving anchors &c. which have been swept or otherwise taken possession of, whether the same have belonged to vessels in distress or otherwise, if such anchors &c. have not been reported &c. according to law. (1 & 2 Geo. IV. c. 75, s. 12; and c. 76, s. 10.)

XI. Transportation for seven years, or imprisonment without hard labour.

1. Assaulting officers on account of the exercise of their duty in the preservation of vessels in distress, &c. (9 Geo. IV. c. 51, s. 24.)

2. Fine of 40l., or if the offender has not goods or chattels, lands or tenements to the value of 40l., then imprisonment by the space of one half-year; &c. and, besides the foregoing punishment, the offender may be imprisoned.

For the purposes of 9 Geo. IV. c. 60, the word "game" includes hare, pheasants, partridges, grouse, bustards, game birds, and beagles. (See 13 & 14 Geo. IV. c. 69, s. 1.)

The punishment for a first offence is imprisonment not exceeding one year.

2. See the 8 & 9 Vic. c. 109, s. 17, which declares that persons winning such game, &c. by chance, may be kept in prison for the time of derelicting such money, &c. by false pretences, and shall be punished accordingly. (See 8 & 9 Vic. c. 109, s. 17.)

3. The punishment for a misdemeanor at common law is fine and imprisonment.

The only cases are when the offender is prosecuted under 5 Eliz. c. 9. that he is liable to this portion of these penalties. If prosecuted at common law he is punishable with fine, &c. of which either may be sentenced to the other penalties stated above. The common law offence extends also to imposition of property in any judicial proceedings.
with hard labour for a term not exceeding seven years, or transported for a term not exceeding seven years; and, in addition to or in lieu of the before-mentioned punishments, may be imprisoned with hard labour for any term not exceeding the term for which he may be imprisoned as aforesaid; and the offender on conviction cannot therefor be received as a witness in any Court, unless the judgment given against him be reversed.

1. Subornation of perjury in any of the Queen's Courts of Chancery or Courts of Record, or in any Lact, View of Francisques, or in any Court of the United of the United of the Court, or in the Court or Courts of the Stannary in the counties of Devon and Cornwall; or subornation witnesses sworn to testify that peremptory rei memoriam.  ⁶ (5 Eliz. c. 9, s. 2; 2 Geo. II. c. 25, s. 2; 3 Geo. IV. c. 114; 7 Wm. IV. & 1 Vict. c. 25.)

XIII. Fine of 20l. and imprisonment for six months; ⁷ and besides the before-mentioned punishment the offender may be imprisoned with hard labour for a term not exceeding seven years, or transported for a term not exceeding seven years; in addition to or in lieu of the before-mentioned punishments, may be imprisoned with hard labour for any term not exceeding the term for which he may be imprisoned as aforesaid; and the offender on conviction cannot therefor be received as a witness in any Court, unless the judgment given against him be reversed.

1. Perjury in any of the Courts mentioned above in the case of subornation of perjury, or by any person examined as a witness.  (6 Eliz. c. 5; 21 Janc. I. c. 26, s. 8; 2 Geo. II. c. 25, s. 2; 3 Geo. IV. c. 114; 7 Wm. IV. & 1 Vict. c. 23.)

2. Sowen or marines attempting to obtain their pay by means of forged certificates of their discharge from the queen's ships, or from hospitals or sick-quarters.  (11 Geo. IV. & 1 Wm. IV. c. 20, s. 89; 7 Wm. IV. & 1 Vict. c. 23.)

3. Forgery of certificates of the Commissioners for executing the Act of Lord High Admiral, of the purchase or sale of any naval or signalling vessels.  (2 Wm. IV. c. 40, s. 32; 7 Wm. IV. & 1 Vict. c. 23.)

4. Making false declarations or signing false notices for the purpose of preventing marriages; ⁸ or

5. Forbidding the issue of any superintendent registrar's certificate, by falsely representing oneself to be a person whose consent to such marriage is required by law.  (6 & 7 Wm. IV. c. 4, s. 98; 7 Wm. IV. & 1 Vict. c. 23; 3 & 4 Vict. c. 72, s. 4.)

6. Making false statements for the purpose of their being inserted in registers of births, deaths, or marriages.  (6 & 7 Wm. IV. c. 4, s. 99; 7 Wm. IV. & 1 Vict. c. 29.)

XIV. Transportation for seven years, or imprisonment with hard labour for any term not exceeding three years.

1. Assaulting or obstructing persons duly employed for the purpose of the peace or for the public good, with high official capacity.  (6 & 7 Wm. IV. c. 4, s. 97; 7 Wm. IV. & 1 Vict. c. 29.)

XV. Transportation for seven years, or imprisonment with or without hard labour for any period not exceeding three years; and during such imprisonment the offender may be publicized or whipped at public meetings in such manner and form as the Court shall direct, not exceeding thrice.

1. Discharging or aiming fire or other arms, or discharging or attempting to discharge any explosive substance, at or near the person of the queen, or striking or attempting to strike at the person of the queen, or in any other manner throwing or attempting to throw anything at or upon her person, with intent to injure or alarm the queen or breach the public peace, or which the public peace may be endangered; or having fire or other arms, or any explosive or dangerous matter or thing near the queen's person, with intent to use the same to injure or alarm her.  (5 & 6 Vict. c. 88, s. 2.)

XVI. Transportation for five years, or imprisonment for any term not exceeding two years, with or without hard labour or solitary confinement, or with both; and the offender, if a male, may be once, twice, or thrice publicly or privately whipped; and the offender, if a female, may be subjected to such imprisonment as aforesaid.

1. Receiving property the stealing, taking, &c. whereof is made an indictable misdemeanour by 7 & 8 Geo. IV. c. 29, knowing the same to have been unlawfully stolen, taken, &c.  (7 & 8 Geo. IV. c. 26; 4 Vict. c. 17.)

2. Boatmen and others concealing &c. and not reporting according to law, or obliterating the marks &c. on, articles found by them on the coast (provided the stealing of such articles or the act immediately connected is a punishable misdemeanour).  (1 & 2 Geo. V. c. 75, s. 1; and 76.)

3. Maliciously destroying the dams of fish-ponds or millponds, or poisoning fish-ponds.  (7 & 8 Geo. IV. c. 90, ss. 15 and 27.)

XVII. Transportation for seven years, or imprisonment with hard labour for any term not exceeding two years.

1. Taking or destroying game, or rabbits by night, in any land or on any public road, path &c., or at the openings, gates &c. from such land into such public road &c., or entering any such land, by night, with any instrument for that purpose.  (5 & 6 Geo. IV. c. 69, ss. 1, 2; 7 & 8 Geo. IV. c. 26.)

XVIII. Transportation for any term not exceeding seven years, or imprisonment not exceeding two years.

1. Being guilty of an unlawful combination or conspiracy.  (37 Geo. III. c. 129, s. 1; 20 Geo. III. c. 79, ss. 2 and 8; 52 Geo. III. c. 104, s. 1; 57 Geo. III. c. 19, s. 25.)

2. Being present at meetings for the purpose of drugging persons to the use of arms &c., such meetings being unauthorized by her Majesty or the lieutenant or two justices of the peace of the county or riding, by commission or otherwise; or drugging persons to the use of arms &c.  (90 Geo. III. & 1 Geo. IV. c. 1, s. 1.)

XIX. Imprisonment for life, loss of the offender's right hand, and forfeiture of his goods and chattels, and of the profits of his lands during life.

1. Assisting any judge of the queen's courts of law or equity, or any justice of assize, oyer and terminer, or general gaol delivery, whilst acting in his official capacity; or striking any person in the presence of any such judge or justice.  (Hawk. P. c. b. 1. c. 21, s. 3; Seventh Report of the Criminal Law Commissioners, pp. 49 and 160.)

XX. Imprisonment for life and forfeiture of the offender's goods and profits of his lands.

1. Recruising prisoners being in the presence of any such judge who shall have the power of his official capacity.  (Hawk. P. c. b. 1. c. 21, s. 5; Seventh Report of the Criminal Law Commissioners, pp. 49 and 160.)

XXI. Imprisonment for life, and forfeiture of all goods and chattels of the offender.

1. Being a second time convicted of publishing fond, fantastical or false prophecies, to the intent thereby to make any rebellion or other disturbance &c. within the queen's dominions.  (3 Eliz. c. 15, s. 3.)

XXII. Imprisonment for life.

1. Hearing and being present at any other form of common prayer &c. than is mentioned and set forth in the Book of Common Prayer, or in speaking in derogation thereof, having been twice previously convicted of the same.  (6 & 6 Edw. VI. c. 1, s. 6; 13 & 14 Car. II. c. 4, s. 24.)

2. Clergymen of the Established Church using any other form of common prayer &c. than is set forth in the Book of Common Prayer, or speaking in derogation thereof, having been twice previously convicted of any such offence.  (1 Eliz. c. 2, s. 6; 13 & 14 Car. II. c. 4, s. 24.)

* See also 12 Geo. I. c. 24, s. 4 (made perpetual by 21 Geo. II. c. 23) as to subornation of perjury and perjury &c. by attorneys &c., for which the Court may cause them, after an examination in a summary way, to be transported for seven years.  8 The punishment for the common offence is the same as for subordination of perjury; and perjury at common law must be proved.  ⁷ Persons are usually carried on for the offence as at common law, and not under the statute.  ⁸ There is a great number of similar acts, besides those mentioned above, which are punishable at common law, for which trial by jury is necessary, or to be punishable as perjury; but it would have occupied too much space to have inserted them here.

This and the next four offences subject the persons committing them to the punishment of perjury.

It may be a question whether the 2 & 6 Vict. c. 51, s. 2, notwithstanding the fact that other provisions are declaratory, or to be punishable as perjury, or to be punishable as perjury, it but it would have occupied too much space to have inserted them here.
3. Persons not having any spiritual promotion committing any such last-mentioned offence, after their first conviction. 1 (1 Eliz. c. 2, s. 8; 15 & 16 Car. II. c. 4, s. 24.)

4. For attempting or conspiring anything in derogation of &c. the Book of Common Prayer, or compelling or causing any person or other minister to use any other form of common prayer &c. than is mentioned in the said book, or in saying or keeping any place of worship, or in saying common prayer &c. in the form mentioned in the said book, having been twice previously convicted of any such offence. 2 (1 Eliz. c. 2, s. 11; 15 & 16 Car. II. c. 4, s. 34.)

12. Imprisonment, or being deprived of all his spiritual benefices or promotions or sitting or acting in any place of worship, after his second conviction; or for his second or third offence, to be deprived of all his spiritual promotions. 1 (1 Eliz. c. 2, s. 1, s. 5, &c.)

13. The punishment for the first offence is imprisonment for one year. 1 (Eliz. c. 2, s. 5.)

The punishment for the first offence is forfeiture of 100 marks, or, if the offender do not pay the same within six weeks after his conviction, six months imprisonment instead; and for the second offence is forfeiture of 400 marks, or, if the offender do not pay the same within six weeks after his conviction, twelve months imprisonment instead. 1 (1 Eliz. c. 2, s. 9, 10, 12, and 13.)

24. The punishment for any term not exceeding twelve months imprisonment, nor less than six months, and the offender to be liable to such other punishment as may by law be inflicted in cases of high misdemeanors.

31. Refusing to give any information tendered to excite hatred of the queen, &c., as having been previously printed in some foreign paper which has not been so printed. 38 Geo. III. c. 78, s. 24.

32. Fine and imprisonment, with or without hard labour or solitary confinement, or with both.

33. Refusing to deliver up &c. post-offices which ought to have been delivered to any other person, or post-offices which shall have been found by the person so refusing, or by any other person, &c. 7 Wm. IV. & 1 Vict. c. 36, ss. 31 and 42.

35. Fine and imprisonment, and such corporal punishment by public or private whipping as the court shall direct. 5 Geo. IV. c. 77, s. 2, 3. and c. &c.

52. The Church of England was deprived of all rights and privileges within the United Kingdom, admitting any person to become a member of any such order or society. 10 Geo. IV. c. 7, s. 23.

57. Parish officers refusing to call meetings, &c. according to the provisions of the Act for the better Regulation of Vestries. 1 & 2 Wm. IV. c. 60, s. 11.

58. Making false answers to any of the questions directed by the Reform Act to be put by the returning officer at elections of members of parliament, if required by any candidate, to any voter at the time of his tendering his vote. (2 & 3 Wm. IV. c. 45, s. 8.)

77. Forgery, &c. of protection from service in the navy. 5 & 6 Wm. IV. c. 24, s. 3.

78. Making false declarations in cases where declarations are substituted for oaths by the Act for abolishing unnecessary Oaths. 5 & 6 Wm. IV. c. 62, s. 21.

79. Executing &c. renewed ecclesiastical leases, knowing the recital required by law contained therein to be false. 6 & 7 Wm. IV. c. 76, s. 6.

80. Making false statements in declarations required to be delivered to the Commissioners of Stamps and Taxes before being allowed to print and publish newspapers. (6 & 7 Wm. IV. c. 76, s. 6.)

81. Making, &c. false declaration of being qualified to be elected a member of the House of Commons. (1 & 2 Vict. c. 48, s. 7.)

82. Frauds in assignments of pensions for service in her Majesty's navy, royal marines or ordnance. (2 & 3 Vict. c. 51, s. 8.)

83. Making false declarations touching any of the matters contained in the Act for procuring Returns relative to Highways and Turnpikes. * (2 & 3 Vict. c. 40, s. 9.)

84. Officers of railways making false returns, under the discretion of the entrance, commitment or discharge of such prisoners, or detaining prisoners for non-payment of fees.* (55 Geo. III. c. 50, s. 13.)

85. Fishing off, &c., by persons having charge of stage-coaches or public carriages, not being hackney-coaches drawn by two horses only, and not plying for hire as stage-coaches, whereby any person is injured. (1 Geo. IV. c. 4.)

86. Buying or offering to buy, or procuring any place of business in any manner relating to the sale or purchase thereof. 5 & 6 Edw. VI. c. 16; 40 Geo. III. c. 196, s. 3; 6 Geo. IV. c. 105, s. 10.)

3. Officers exacting fees from prisoners against whom no bill of indictment is found by the grand jury, or who are acquitted on their trial or discharged by proclamation for want of prosecution. 2 (55 Geo. III. c. 50, ss. 4 and 5.)

4. Officers of game or Excise by their misconduct causing waste, &c. in merchandise warehoused in warehouses under the Act for permitting goods imported to be secured in warehouses without payment of duty on first entry. (4 Geo. IV. c. 24, s. 72.)

5. By false certificates or representations endeavouring to obtain from Chelsea Hospital any pension, privilege or advantage. 3 (7 Geo. IV. c. 16, s. 25.)

6. Setting spring-guns or man-traps, except within a dwelling-house, between sun-set and sun-rise, for the protection thereof. 7 & 8 Geo. IV. c. 18, ss. 1 and 4.)

62. Jesus, or members of any religious order or society of the Church of Rome, and other societies which are of a contrary nature, within the kingdom, admitting any person to become a member of any such order or society. 10 Geo. IV. c. 7, s. 23.

63. Parish officers refusing to call meetings, &c. according to the provisions of the Act for the better Regulation of Vestries. (1 & 2 Wm. IV. c. 60, s. 11.)

64. Making false answers to any of the questions directed by the Reform Act to be put by the returning officer at elections of members of parliament, if required by any candidate, to any voter at the time of his tendering his vote. (2 & 3 Wm. IV. c. 45, s. 8.)

65. Refusing to attend, &c. the Poor Law Commissioners (4 & 5 Wm. IV. c. 76, s. 13); the Tithe Commissioners (6 & 7 Wm. IV. c. 71, s. 83); or the Copyhold Commissioners (4 & 5 Vict. c. 85, s. 94).

66. Forgery, &c. of protection from service in the navy. (5 & 6 Wm. IV. c. 24, s. 3.)

67. Executing &c. renewed ecclesiastical leases, knowing the recital required by law contained therein to be false. (6 & 7 Wm. IV. c. 76, s. 6.)

68. Making false statements in declarations required to be delivered to the Commissioners of Stamps and Taxes before being allowed to print and publish newspapers. (6 & 7 Wm. IV. c. 76, s. 6.)

69. Making, &c. false declaration of being qualified to be elected a member of the House of Commons. (1 & 2 Vict. c. 48, s. 7.)

70. Frauds in assignments of pensions for service in her Majesty's navy, royal marines or ordnance. (2 & 3 Vict. c. 51, s. 8.)

71. Making false declarations touching any of the matters contained in the Act for procuring Returns relative to Highways and Turnpikes. * (2 & 3 Vict. c. 40, s. 9.)

72. Officers of railways making false returns, under the discretion of...
Act for regulating railways, to the committee of the Privy Council for Trade. (3 & 4 Vict. c. 97, s. 4.)
23. Making false returns of corn, under the Act regulating the importation of corns. (5 & 6 Vict. c. 14, s. 42.)
24. Making false entries in the Register Book of Copyrights. (5 & 6 Vict. c. 45, s. 12.)
25. Voters making false answers to returning officer at elections of members of parliament. (6 & 7 Vict. c. 18, s. 81.)
26. Actuaries or other persons holding appointments in savings' banks, receiving deposits and not paying the same over to the managers of such banks, &c. (7 & 8 Vict. c. 83, s. 4.)
27. The registrar of joint-stock companies or any person employed under him, demanding or receiving any gratuity, or reward beyond the fees allowed by law. (7 & 8 Vict. c. 110, s. 22.)
28. Directors of joint-stock companies by whom certificates of shares are issued, making false statements on such certificates as to the date of the first complete registration of such companies. (7 & 8 Vict. c. 110, s. 26 in part.)
29. Persons knowing dogs or skins of dogs found in their possession, by virtue of a search warrant, to be stolen dogs, or the skins of stolen dogs (for the second offence). (8 & 9 Vict. c. 47, s. 3 in part.)
30. Corruptly taking any reward for aiding persons to recover stolen &c. dogs. (8 & 9 Vict. c. 47, s. 6.) 31. Obstructing the provisions of the 8 & 9 Vict. c. 100 (An Act for the regulation of the care and treatment of Lunatics), and the 8 & 9 Vict. c. 126 (An Act to amend the laws for the provision and regulation of Lunatic Asylums for counties and boroughs; and for the maintenance and care of Pauper Lunatics in England), declared by those Acts to be misdemeanours.
32. Using contemptuous words or gestures of or against the queen.
40. Blasphematic or seditious libels.
41. Unlawfully refusing to serve public offices.
42. Executing official duties before taking oath of office and giving security, where the same are required by law.
43. Wilfully disobeying any statute, by doing what it prohibits or omitting what it commands, whereby the public are or may be injured.
44. Wilfully disobeying any lawful warrant, order or command of her Majesty, or any court or person acting in a public capacity and duly authorized in that behalf, where no other penalty or mode of proceeding is expressly provided. 45. Obstructing officers in the execution of any public office or duty.
46. Excess or abuse of authority by public officers. 47. Extortion by public officers.
48. Fraudulent misapplication by public officers of property under their control as such officers.
49. Unlawfully, and contrary to oath of office, disclosing the matter of knowledge of which has been acquired in an official capacity.
50. Assaulting &c. persons on account of anything done by them in connexion with any judicial proceeding.
51. Contempts of courts of justice or magistrates, by uttering any words, or more menacing or menacing words, or by as to gestures expressed or done in the face of such courts or in the presence of such magistrates.
52. By force, or by violent or outrageous conduct, interrupting the proceedings of courts of justice.
53. The wilful omission by judicial officers to do their duty.
54. Oppression by judicial officers.

*The first offence is punishable on summary conviction before two or more justices by payment of such sum, not exceeding 25l., as to the justice shall award.*

[This and the following fifty-two offences (29 to 44 inclusive) are made misdemeanours, by the Criminal Law Amendment Act, 1861 (6 & 7 Vict. c. 102).]

2, 3 & 4. Vict. c. 98, s. 70. [These offences, when committed for a second time, were made punishable at the discretion of the court, by 60 Geo. Ill. 1 & 2 Geo. IV. c. 4; but 12 Geo. IV. 1 & 2 Wm. IV. c. 23, repealed the latter portion of the punishment.]

LAW

55. Judicial officers taking bribes.
56. Bribery or otherwise corruptly influencing judicial officers.
57. Persons procuring themselves to be returned as jurors, with intent to obtain a verdict or any undue advantage for any person interested in a trial.
58. Unlawfully preventing persons from serving as jurors.
59. Justices receiving their venire fees or any mode of chance.
60. Witnesses refusing to be sworn or to give evidence in judicial proceedings.
61. Unlawfully preventing witnesses from giving evidence in judicial proceedings.
62. Endavouring to procure the commission of perjury.
63. Publishing statements, pending suits or prosecutions, with intent to excite prejudice for or against any party to such suits or prosecutions.
64. Fabricating false evidence.
65. By disposing of dead bodies, without giving notice to the coroner, in cases where inquests ought to be taken, obstructing the taking of such inquest.
66. Glaazers and others, contrary to their duty, allowing dead bodies to remain unburied or putrefy, without giving notice to the coroner, in cases where inquests ought to be taken.
67. Challenging or provoking to fight, or to commit a breach of the peace.
68. Open indecency in places of public resort or in view thereof.
69. Keeping gaming or other disorderly houses.
70. Arresting or otherwise obstructing the burial of dead bodies.
71. Unlawfully disinterring dead bodies.
72. Building or selling wines.
73. Selling unwholesome provisions.
74. Maliciously exposing persons labouring under contagious diseases in places of public resort.
75. Common innominate.
76. Corrupting wells or springs used by the public.
77. Innkeepers refusing to receive travellers, their lads not being fully occupied at the time, and a reasonable sum being tendered for accommodation.
78. Battery.
79. False imprisonment.
80. Assaults.
81. Persons maiming themselves, with intent to evade the discharge of any public duty.
82. Cheats.
83. Forgery, in cases where no punishment is provided by statute.
84. Concealing treasure-trove.
XXXI. Forfeiture, fine not exceeding 200l., and costs of suit, and also. Such further fine or imprisonment, or any of them, in such manner and for such space of time as to the court shall seem meet.
1. Being possessed (not being a contractor with the Commissioners of Her Majesty's Ordnance or a Vestigial Office for Her Majesty's use) of any of her Majesty's stores called can-vas, or bewer, otherwise called buntin, or of any cordage wrought with one or more worsted threads, or of any other public stores, or same not being charged to be new, or not more than one-third worn. (38 & 40 Geo. III. c. 89, s. 2; 54 Geo. III. c. 60; 55 Geo. III. c. 127; 56 Geo. III. c. 138, s. 2.)
2. Making, being possessed of, or concealing (not being a contractor as last mentioned) any warlike or naval stores, with the marks used by her Majesty's warlike, naval, or ordnance stores, or any other public stores. (38 & 40 Wm. IV. c. 114, s. 1. i. c. 8; 17 Geo. II. c. 40; 29 & 40 Geo. III. c. 88, s. 2; 54 Geo. III. c. 59; 55 Geo. III. c. 127; 56 Geo. III. c. 138, s. 2.)
XXXII. Fine not exceeding 500l., or imprisonment for any term not exceeding two years, or both.
1. Aiding the escape of convicts from New South Wales or Van Diemen's Land. (9 Geo. IV. c. 83, s. 34.)
XXXIII. Imprisonment, with or without hard labour, for such term as the court shall determines.
1. Unlawfully and carnally knowing girls above the age of ten and under age of twelve years. (9 Geo. IV. c. 31, s. 17.)

2. Unlawfully taking, or killing hares or conies, in the night time, in warrens. (7 & 8 Geo. IV. c. 29, ss. 4 and 30.)

3. Unlawfully destroying, or despoiling any birds running through or in lands adjoining or belonging to dwelling-houses. (7 & 8 Geo. IV. c. 29, ss. 4 and 34.)

4. Unlawfully destroying turpik or toll gates or houses, &c. (7 & 8 Geo. IV. c. 29, s. 34.)

5. Officers of the Post-Office opening or detaining post letters! (7 Wm. IV. & 1 Vict. c. 36, ss. 25 and 42;) or stealing, embezzling, or destroying printed or proceedings in Parliament, or newspapers, or other printed papers sent by the post, without covers or in covers open at the sides. (7 Wm. IV. & 1 Vict. c. 36, ss. 32 and 42.)

6. Forgery of bills, or false impositions or imitations of bills, &c. (1 & 2 Wm. IV. c. 22, s. 25;) of stage-carriage tickets (2 & 3 Wm. IV. c. 120, s. 32;) or of the licences or tickets of drivers of hackney-carriges, drivers of stage-carriges, or watermen (1 & 2 Wm. IV. c. 79, s. 12.)

7. Frauds in applying for hackney-carriges or stage-carriage licences. (1 & 2 Wm. IV. c. 22, s. 33; 2 & 3 Wm. IV. c. 10, s. 3.)

8. Compounding offences, or otherwise offending against the provisions of the 18 Eliz. c. 5 (An Act to redress disorders in common lodging Eliz. 6, s. 4; 27 Eliz. c. 10; 56 Geo. III. c. 138, s. 2.)

9. Resisting the execution of any legal process, execution, or extent, taken out by persons having debts owing to them from persons residing within the Parishes, Savoy, Salisbury Court, Ram Alley, Mitre Court, Fuller's Rest, Baldwin's Gardens, Montague Close, or the Minorities, Mint, Clink, or Deadman's Place. (6 & 9 Wm. III. c. 27, s. 12; 56 Geo. III. c. 138, s. 2.)

10. Illegal brokerage. (53 Geo. III. c. 141, s. 9.)

11. Persons having the custody of offenders ordered to be confined in Parkhurst Prison, or Pentonville or Millbank Prison, ready to be committed to such offenders, or to the custody of persons employed about the performance of divine service. (9 Geo. IV. c. 31, s. 25.)

12. Frauds by Excise officers in the granting of permits, or in the performance of their duties in relation to the same. (2 Wm. IV. c. 16, s. 15.)

13. Altering, destroying, counterfeiting, or trafficking in the register-tickets with which merchant seamen are required to provide themselves. (7 & 8 Vict. c. 112, s. 22.)

14. Making false answers to questions by the registrar of seamen, &c. with reference to the granting of such tickets. (7 & 8 Vict. c. 112, s. 22.)

15. Masters of merchant ships, without the sanction of the consul, &c., discharging or abandoning abroad persons belonging to their ships or crews, or, in case any such person should desert, or be neglected, or have been abandoned in writing to such consul, &c. (7 & 8 Vict. c. 112, s. 46.)

16. Masters, mates, or other officers of merchant ships, wrongfully foregoing on shore, or leaving behind on shore or at sea, persons belonging to their ships or crews, before the completion of the voyage for which such persons were engaged, or the return of their ships to the United Kingdom.* (7 & 8 Vict. c. 112, s. 47.)

17. Masters of merchant ships omitting, when required by the consul, &c., on the complaint of three or more of their crew, to provide proper provisions, water, or medicines, or of the requisite place of storage, or, in using any provisions, &c. which the consul, &c. shall have signified to be unfit for use or inappropriate. (7 & 8 Vict. c. 112, s. 57.)

**This offence does not extend to angling in the daytime; but persons desiring to use angling as a trade, or as a means of livelihood, are obliged to obtain a licence under the provisions of the Act, which contains regulations and restrictions designed to protect the interests of the angling fraternity.*

---

* See also 9 Geo. IV. c. 51, s. 50, which makes it a misdemeanour, punishable with imprisonment for such term as the court shall think fit, to prevent merchant ships to force on shore or refuse to bring home all such men of the merchant marine as they can carry or can with advantage return to England. The effect of the offences of Chapmastry and Maintenance is recommended by the Criminal Law Commission (Fourth Fifth Report.)

---

2. Being armed, assaults Excise officers whilst searching for or seizing commodities forfeited under any Act relating to the Excise or Customs, or whilst endeavouring to arrest offenders. (7 & 8 Geo. IV. c. 58, s. 10.)

3. Improving for any term not exceeding three years, with or without hard labour or solitary confinement, or with both.

4. Being possessed of three or more pieces of counterfeit coin, intended to pass for the Queen's current gold or silver coin, knowing the same to be counterfeit and with intent to utter the same. (2 Wm. IV. c. 34, ss. 8 in part and 15.)

5. Improving for any term not exceeding three years, with or without hard labour.

6. Bankruptcy of holders of incorporated commercial or trading companies which shall be adjudged bankrupt, falsifying or destroying their books, &c., with intent to defraud their creditors. (5 & 6 Vict. c. 122, s. 24; 7 & 8 Vict. c. 111, s. 30.)

7. Publishing or threatening to publish libels, &c. with intent to extort money, &c. (6 & 7 Vict. c. 66, s. 9.)

8. Improving for one year and grievous fine for the queen's pleasure; or if the offended have not whereof, imprisonment for three years.

9. Misrepresentation by sheriffs, coroners, or other bailiffs. (3 Edw. I. c. 9.)

10. Improving for one year and grievous fine; or if the offended have not whereof, imprisonment for two years.

11. Bailiffs not being ready, on the hue and cry, to arrest felons. (3 Edw. I. c. 9.)
XLVI. **Improvement** with or without hard labour for any term not exceeding two years, and fine if the court shall think fit; and the offender may be required to find sureties for keeping the peace.

1. Assails with intent to commit felony, or on any place or road, or with intent to resist the lawful apprehension or detention of any person, or in pursuance of any conspiracy to raise the rate of wages (9 Geo. IV. c. 81, s. 25); or on special constables.*

2. Maliciously publishing seditious libels, knowing them to be false. (6 & 7 Vict. c. 96, s. 4.)

**XLVII.** _Improvement_ for any term not exceeding two years, with or without hard labour or solitary confinement, or with both.

1. Soliciting the commission of any felony or misdemeanor punishable by the Post-Office Acts. (7 Wm. IV. c. 1 & 2 Wm. IV. c. 1, s. 1.)

2. Bankrupt, within three months next preceding his bankruptcy, of obtaining goods on credit under the false pretence of selling in the ordinary course of trade. (6 & 6 Vict. c. 129, s. 35.)

3. Drunkenness or other misconduct of servants of railway companies‡

**XLVIII.** _Discourtesy_ for a term not exceeding two years.

1. Embracing on board slaves in the capacity of petty officers, seamen, &c. (5 Geo. IV. c. 119, s. 11; 3 & 4 Wm. IV. c. 73.)

2. Doing any thing to obstruct carriages on railways or to endanger the safety of persons conveyed upon the same. (3 & 5 Vict. c. 97, s. 18.)

**XLIX.** _Improvement_ for one year, and such further punishment by fine or imprisonment, or both, as to the court shall seem most proper, and the offender to give sureties for good behaviour and to further improve himself before they be given.

1. Withholding, fraud, forgery, selling, &c., or pretending to discover where property supposed to be stolen or lost may be found. (9 Geo. IV. c. 5, s. 4; 56 Geo. III. c. 138, s. 2.)

2. _Improvement_ not exceeding eighteen months, or with or without hard labour.

1. Dog-stealing; for the second offence‡. (8 & 9 Vict. c. 47, s. 2 in part.)

L. **Forfeiture** of goods and chattels, real and personal, and the offender not having goods and chattels to the value of 20l. then, in addition, _imprisonment_ for one year.

1. Maintaining the authority, spiritual or ecclesiastical, of any foreign prince or state claimed within this realm or any of the dominions under the queen's oblogeance before the passing of the 1 Eliz. c. 1.§ (1 Eliz. c. 1, ss. 27 and 28; 7 & 8 Vict. c. 102.)

LIV. **Improvement** for any term not exceeding one year, with or without hard labour or solitary confinement, or with both.

1. Uttering counterfeit coin intended to pass for the queen’s current copper coin, or being possessed of three or more pieces of such coin with intent to utter the same. (2 Wm. IV. c. 84, ss. 12 and 19.)

* Assaults on special constables may also be punished on summary conviction before two justices. (See 1 & 2 Wm. IV. c. 41.)

But see 7 Wm. IV. & 1 Vict. c. 5, s. 5, which limits the time for which the court has discretion to allow imprisonment on a complaint before a magistrates to a term not longer than one month as a time, or three months in a year. It may be a question whether the above provision, by the Statute 20 Geo. IV. c. 46, s. 3, does not empower the court to impose a term exceeding three months in the case of disqualification of a person, the judgment of which will have an effect of disfranchising a person, or to impose a term exceeding three months in the case of disqualification of a person, the judgment of which will have an effect of disfranchising a person.

† The first offence is punishable on summary conviction, with imprisonment not exceeding a calendar month, or fine not exceeding 10s., if the justice before whom complaint is made directs it to be so decided upon it, instead of sending it to the Quarter-Sessions.

‡ The second offence is punishable on summary conviction, with imprisonment not exceeding six calendar months, or with or without hard labour, or with forfeiture not exceeding 200l. over and above the fine of the value of the goods or goods. The offence shall in no case exceed £400.

§ This forfeiture, being by statute, does not, as above observed, constitute the offence of forgery.

‖ The repeal of this offence is recommended by the Commissioners for reforming the offender in such cases.

* But see 7 Wm. IV. & 1 Vict. c. 5, s. 5, which limits the time for which the court has discretion to allow imprisonment on a complaint before a magistrate to a period not longer than one month as a time, or three months in a year. It may be a question whether the above provision, by the Statute 20 Geo. IV. c. 46, s. 3, does not empower the court to impose a term exceeding three months in the case of disqualification of a person, the judgment of which will have an effect of disfranchising a person, or to impose a term exceeding three months in the case of disqualification of a person, the judgment of which will have an effect of disfranchising a person.

**L.** _Improvement_ for any term not exceeding one year, with or without hard labour or solitary confinement, or with both.

1. Maliciously publishing seditious libels. (6 & 7 Vict. c. 96, s. 5.)

**LV.** _Solitary improvement_ for a space not exceeding twelve nor less than three calendar months.*

1. Persons having hired stocking-frams, unlawfully disposing of them without the consent of the owners. (26 Geo. III. c. 55, s. 3.)

2. Knowingly receiving or purchasing such stocking-frams as unlawfully disposed of. (28 Geo. III. c. 55, s. 3.)

**LVI.** _Fine_ of 100l. or _imprisonment_ with hard labour for any term not exceeding one year, at the discretion of the court.

1. Making signals between sunset and sunrise from the 21st of September to the 1st of April, and between 8 p.m. and 6 a.m. at any other time of the year, for the purpose of giving any notice to persons on board smuggling vessels, whether such persons be or be not within distance to notice such signals. (8 & 9 Vict. c. 87, s. 60.)

**LIX.** _Fine_ of 600l., and the offender to be rendered incapable of holding any office or place under the crown.

1. Judges and other officers or persons demanding or taking any money or other thing of value for anything done or pretended to be done under any Act relating to bankrupts, beyond what is allowed by such Acts. (1 & 2 Wm. IV. c. 80, s. 58.)

2. Masters in Chancery, or persons holding offices in the Court of Chancery, or under any of the officers thereof, demanding or taking any emolument or other thing of value, other than is allowed to be taken for anything done or pretended to be done relating to their offices or employments.† (3 & 4 Wm. IV. c. 94, s. 41.)

**LXI.** _Fine_ of 200l. for six months.

1. Bailiffs, or other chief officers of towns corporative, designedly hindering the election of other mayors, &c. in the same towns corporative.‡ (11 Geo. I. c. 4, s. 6.)

2. Being not bona fide acting as guardians or receivers of silver, buying or selling bullion or molten silver. (6 & 7 Wm. III. c. 17, s. 7.)

3. Persons suspected of buying or selling unlawful bullion, in whose hands such bullion shall be found, not proving upon their trial for melting the current coin of the realm, by one witness at the least, that the same was lawful silver and not current coin, nor clippings thereof. (6 & 7 Wm. III. c. 17, s. 8 in part.)

**LXI.** _Half a year’s_ imprisonment, and ransom at the queen’s will§.

1. Marshals of the Queen’s Bench suffering prisoners indicted for felony, who have removed the same indictment before the queen, to wander out of prison by bail or without. (6 Edw. III. c. 8.)

**LXII.** _Fine_ for any period not exceeding six months, or _imprisonment_ of the offender, if a male, may be put to hard labour, or be once, twice or thrice privately whipped, in such manner as the court shall direct.

1. Maliciously damaging anything kept for the purposes of art, science or curiosity, or as an object of curiosity, in any museum or other repository, which is at all times or from time to time open to the public or any considerable number of persons, either by permission of the proprietor or by payment of money, or any picture, statue, monument or painted glass in any place of public worship, or any statue or monument exposed to public view. (8 & 9 Vict. c. 44, s. 1.)

**LXIII.** _Improvement_ for any time not exceeding six calendar months.

1. Making false declarations under the provisions of the Act for regulating the manner of making sureties of the duties of excise taxes.¶ (50 Geo. III. c. 105, s. 9.)

**LXIV.** _Fine_ not exceeding 100l. and three months’ _imprisonment_.

1. Procuring the consent of more than twenty persons to any petition or other address to the queen or either house of
parliament, for attention of matters establishd by law in church or state, without the previous order of three or more justices, or even a single justice of the grand jury of the county, where the matter arises at the assizes or quarter-sessions, or, if arising in London, of the lord mayor, aldermen, and commons, in common council assembled; or, upon pretence of presentment and petition or other means being inviolate, and by a greater number of people, or at any one time with above ten persons. 

II. Fine not exceeding 20l., or imprisonment with or without hard labour, for any term not exceeding three months, or, fine not exceeding 50l.,

III. Offending against the provisions of the Act for regulating schools of anatomy. (3 & 3 Wm. IV. c. 75, s. 18.)

IV. Fine not less than 20l., and imprisonment with or without hard labour.

V. Neglecting or disobeying the orders of the Poor Law Commissioners or assistant commissioners, having been twice previously convicted of so doing: (4 & 5 Wm. IV. c. 76, s. 1.)

VI. Imprisonment until the offender brings into court him which was the first author of the tale, and, if he cannot find, any other person with which the panel shall accord; or, with any other person, willfully concealing the estate of such person, committed by him, (3 & 11 W. Vict. c. 11, s. 17.)

VII. Fine of 40l.

VIII. Disturbing any religious assembly allowed by law. (1 Wm. & Mar. c. 18, s. 16; 31 Geo. III. c. 92, s. 10; § 12 Geo. III. c. 155, s. 1.)

IX. Fine or imprisonment. (5 Geo. IV. c. 50, s. 61.)

X. Bravery according to the laws. (6 Edw. I. c. 10.)

XI. Illegal distress. (32 Henry III. cc. 1, 2, 3, 4; 8 Edw. I. c. 16.)

XII. Fine and ransom at the queen's will and pleasure.

XIII. Judges or clerks raising rolls, changing verdicts, &c. whereby ensues disbarrement of any of the parties. (8 Rich. II. c. 4.)

XIV. Penalties for persons bolding commissions to compound for the payment of first-fruits. (26 Hen. VIII. cc. 8, 4; 1 Edw. I. c. 4, s. 24.)

XV. Grievious fine to the queen.

XVI. Being or being supposed to be committing impiety, or engaged in any foreign war, or any sum of money, or other business, to the damage of the queen, or any of her crown's dominions, or Papists keeping school or educating youth within the same, whereby, upon conviction, they become liable to perpetual imprisonment; and, for every second and other offences like imprisonment, and to forfeit 12l. to the queen. (13 & 14 Car. II. cc. 4, s. 11 and 12; 1 Wm. and Mar. sess. 1, c. 8, s. 11.)

XVII. Poaching, priests, or Jesuits, saying mass or exercising any other of their functions within the queen's dominions, or Papists keeping school or educating youth within the same, whereby, upon conviction, they become liable to perpetual imprisonment. (11 & 12 Wm. III. c. 4, s. 4.)

XVIII. Roman Catholics were also liable to many other severe penalties for promoting or exercising their religion, until these were repealed by 7 & 8 Vict. c. 102. It will be seen that the two former of the above offences no longer apply to Roman Catholics. The two latter are, however, still in force with respect to them as well as all other classes of the queen's subjects.

The offence of forbearing to resort to church is repealed by the Protestant Dissenters' Toleration Acts (1 Wm. & Mar. sess. 1, c. 16, ss. 13 and 16; and 52 Geo. III. c. 155, ss. 4 and 14) in favour of Dissenters who go to some congregation for religious worship, and protestants shall enjoy the same. Quakers, however, must also, in addition, make the declaration of fidelity, as it is called, and subscribe a profession of their Christian belief. By the provisions of the same Acts, the offence of relieving, harbouring, or protecting an Ran Sous was also punishable as treason.

The above offence does not apply to the delivery of false-currants, or of removing from the land of the lord mayor, aldermen, and commons, held under the provisions of 9 Geo. III. c. 13, for any better supplying the city with London and other fish, to which a large quantity is annually exported. Persons committing this and the next offence may be proceeded against by indictment, or by indictment and on information, and, if on information, by the county court, with a penalty not exceeding £10. 

As to other exceptions see 29 Car. II. c. 5, ss. 10 and 11; 11 W. III. c. 14, § 1; 4 Geo. IV. c. 100, 8 Geo. III. c. 72, and 18 Geo. III. c. 83; (cit. 1 & 8 Vict. c. 92, s. 37.)

By the same act persons who use oaths are declared to be incapable of ever being elected to any of the offices held in the Lord's Day, or to vote for the same.
repealed in favour of Quakers who make the declaration and
subscribe the profession before alluded to, and of all other
Protestant Dissenters who resort to some congregation for
religious worship of Protestants allowed by law, or take the
oaths of allegiance and supremacy, or (since the passing of
the 3 & 4 Wm. IV. cc. 49 and 82, in case such Dissenters
were Moravians or Separatists) make an affirmation to the
effect of such oaths. The penalties imposed upon schoolmasters
teaching without licence from the archbishop, &c. are re-
pealed in favour of Protestant Dissenters who take the oaths
of allegiance and supremacy (or, if Moravians or Separatists),
make an affirmation to the effect of such oaths. If, however,
if Quakers, make the declaration of fidelity and profession of
their Christian belief before alluded to, and make a declaration
that they believe in the Scriptures as received among Protestant
churches. (1 Wm. and Mary, sess. 1. c. 18. s. 13; 8 Geo. I. c. 6; 19 Geo. III. c.
44, s. 2; 10 Geo. IV. c. 7. s. 1; 3 & 4 Wm. IV. cc. 49
and 82.) Pojish bishops, &c. saying massa, &c. and Papists
keeping school or educating youths, are relieved from the
penalties for so doing, provided they take the oath appointed
by the Roman Catholic Relief Act (10 Geo. IV. c. 7). See
the 31 Geo. III. c. 32. ss. 3, 4, and 13; and 10 Geo. IV.
c. 7, ss. 2 and 25.

Persons committing any of the before-mentioned offences
against the Established Church, may, also, in general, pre-
vent the enjoyment of any such benefits by conforming
themselves to the Church. Members of the Estab-
nished Church are not within the Toleration Acts,
and the only mode, therefore, in which they can escape the
penalties for so conforming, is by conforming to the law.
Neither do those Acts apply to Jews.

There are also two offences, having, however, much more
of a political than of a religious character, which subject the
persons committing them to be adjudged Pojish recusants
convict, and as such to forfeit and be proceeded against.
These, are refusing to take the oaths of allegiance and
abjuration, or to make the affirmations or declarations allowed
by the Toleration Acts, or, when tendered by two justices of the
peace or other authorized persons (1 Geo. I. st. 2. c. 13, s.
10; 8 Geo. I. c. 6; 6 Geo. III. c. 53; 3 & 4 Wm. IV.
c. 49 and 82; 1 & 2 Vict. c. 77); and peers or members of
either House of Parliament, sitting or voting therein or coming
into the queen's presence, before they have taken the
oaths of allegiance and supremacy, or taken or made the oath,
affirmations or declarations allowed by law in lieu thereof.
(20 Car. II. st. 2. s. 2, 5, and 6; 8 Geo. I. c. 6; 31 Geo.
III. c. 32. s. 20; 10 Geo. IV. c. 7. s. 2, 4, and 23; 3 & 4
Wm. IV. cc. 49 and 82; 1 & 2 Vict. c. 77.) Peers and
Members of Parliament are also liable in respect of the latter
offences to many disabilities, to a fine of 500l, in addition
to the penalties consequent on being adjudged Pojish recu-
sants convict. The repeal of the four first-mentioned offences
relating to the Established Church, is recommended by the
Commissioners to Parliament, with a view of making the
criminal law (See their Report on Penalties and Disabilities in regard
to Religious Opinions, dated 30th of May, 1845.) The Com-
missioners also recommend that persons committing the two
last-mentioned offences should no longer be adjudged and
suffer as Pojish recusants convict, but should be punished in
a more direct manner; and that one form of an oath, and one
of an affirmation, should be substituted for the numerous forms
of the oaths of allegiance, supremacy and abjuration, and the
modifications thereof now existing, to be so framed that the
same may be taken by all classes of her Majesty's subjects
without objection on religious grounds.

The whole of the law, written as well as unwritten, re-
lated to the definition and punishment of the above offences,
that is, and the laws as Law and Seed as regards indi-
ectible crimes and their punishments, has been collected
and reduced into one body by the Criminal Law Com-
mmissioners (see their 7th Report), and is thus for the
first time brought with fuller and clearer light to the public at large. Before this reduction the Criminal Law had to be sought for in an
innumerable mass of statutes, reported decisions, records, ancient
and modern, and text-books; and, on that account, could be known
only to a small minority of the learned, and to those engaged in
the practice or administration of the law. The digest so pre-
pared by the Commissioners, and called by them "The Act of
Crimes and Punishments," is comprised in twenty-four
chapters, under the following heads:—

1. Preliminary Declarations and Enactments.
2. Treason and other offences against the State.
3. Offences against Religion and the Established Church
   (including the present the Executive Power of the
   Church).
5. Offences against the Administration of Justice.
6. Offences against the Public Peace.
7. Offences relating to the Coin, and to Bullion, and
   Gold and Silver Coinage.
8. Offences relating to the Public Property, Revenue and
   Funds.
10. Offences relating to the Administration of Registration.
11. Offences against Public Morals and Decay.
14. Offences relating to Trade, Commerce, and Public
    Communication.
15. Homicide and other offences against the person.
16. Libel.
17. Offences against the Habitation.
18. Fraudulent Appropriations.
19. Piracy and Offences connected with the Slave Trade.
20. Malicious Injuries to Property.
21. Forgery and other offences connected therewith.
22. Illegal Solicitations, Conspiracies, Attempts and Re-
    petitions of Offences.
23. Definitions of Terms and Expressions.
Procedure.

Where any of the before-mentioned crimes has been or is suspected to have been committed, the ordinary mode of bringing the accused to justice is as follows:—Unless he surrender himself, he is, in the first place, to be summoned by some magistrate, having jurisdiction, to appear before him, or, as is to be first done, to an attorney-general, and may be procured from some such magistrate. In order to the issuing of a summons or warrant there must be an information laid on oath: the former may be directed either to the accused himself, or his sureties, or any other person whom the magistrate pleases, and must signify the party to be arrested and the offence which is the cause of his arrest. After a summons duly issued and served, he may be brought to appear according to its directions, or in default the magistrate may issue his warrant to apprehend him. After a warrant duly granted, whether a summons has been previously issued or not, the person to whom it is directed is to proceed to arrest the accused (and if for treason, felony, or breach of the peace, may do so on any day, and at any time of the day or night), and to take him to goal or before some magistrate having jurisdiction, according to the manner of the Warrant, and that without any unnecessary delay. It is also lawful for a constable or private person who sees a felony committed, or attempted to be committed, a dangerous felony or tumultuous riot, to arrest the offender, without warrant also any person whom he reasonably suspects of having committed a felony which has actually been committed, and persons found committing thefts or malicious injuries to property or persons may be arrested without warrant, arrest on a reasonable charge made of a felony committed or dangerous wound given, although it afterwards appear that none such had been actually committed or given; also for a breach of the peace committed to him in view; but (except in the case of one of the metropolitarn police, who may arrest under certain circumstances do so upon a charge made of an aggravated assault [see 2 & 3 Vict. c. 47], not for one committed out of his view.) Justices of the peace, sheriffs, coroners, and all other peace officers, have, it would appear, the like power to arrest as constables. Where a party is arrested without warrant, he must be taken before a magistrate within a reasonable time.

On surrendering himself or appearing in obedience to a summons, or being brought before a justice of the peace under a warrant, the justice is to proceed to take the examination of the accused and the information on oath of those who know the facts and circumstances of the case, and to put so much thereof as is material into writing. If a prima facie case be made out, the justice is to commit him to prison (unless he be one of the metropolitan police) and the accused is to be brought before a justice of the peace, if the evidence be neither sufficient to raise a strong presumption of guilt, nor to warrant the dismissal of the charge, the accused is to be detained until the case be taken before two justices at the least, who in such case may admit him to bail (7 Geo. IV. c. 64, s. 1), and, if one of them has signed the warrant of commitment, may admit him to bail, although he confess the matter laid to his charge, or such charge do not appear to be groundless, or the circumstances be such as to raise a presumption of guilt (5 & 6 Wm. IV. c. 33, s. 3). If the accused be brought before two justices in the first instance, they have the like power to bind him to appear and answer to the accused is not bound to plead, the justice may certify that he is of sufficient means and not likely to abscond, or be unable to give security, if the accused be not bound before the second for the commencement of the assizes or sessions at which the accused is to be tried, he is not entitled to an order of discovery in order that he may be delivered without delay or inconvenience to the trial (6 & 7 Wm. IV. c. 114, s. 8).

Before a prisoner can be put upon his trial for any treason or felony, it is necessary that a bill of indictment should be found against him by a grand jury duly returned as some court which has jurisdiction to try parties for crimes by means of a petty jury; or in the case of murder or manslaughter, he may be tried upon the coroner's inquisition. Where the offence with which he is charged is of a treasonable nature, he may be tried either upon a bill of indictment found, as in the case of treason or felony, or upon a criminal information filed against him in the name of the queen. For a prosecution, he may be tried either on a petition or on information presented to the attorney-general, in like manner as in the case of treason in the usual manner pointed out by 1 Rich. II. c. 5, commonly called the Statute of Premunire. This latter mode may, however, be regarded as obsolete.

A bill of indictment must be either so stated as to implicate the Crown, and for being for the public benefit and security, may generally be preferred by any person; but it is not usual for parties to interfere unless they are individually aggrieved by the offence, or fill some office which renders it specially incumbent on them to bring the offender to justice. [INDICTMENT, P. C.] So soon as the grand jury have presented the bill of indictment in court, indexed 'a true bill,' the indictment is complete. If the grand jury find no true bill, the accused, where in custody, is to be at once set at large, without the payment of any fees on account of such discharge (14 Geo. III. c. 20; 55 Geo. III. c. 50; 8 & 9 Vict. c. 114). An indictment may be framed upon the first apprehension of the person by the grand jury, their own knowledge that an offence has been committed; but this mode of prosecution is seldom adopted. For further particulars relating to this mode of proceeding, see 31 Car. II. c. 2, s. 7.

A criminal information in the name of the Queen is a suggestion filed on record by the attorney-general or by the queen's coroner or master of the Crown Office, in the court where the accused has been or is an alleged offender. The attorney-general, or, during vacancy in that office, the solicitor-general, may at his discretion file a criminal information. In all other cases it is in the discretion of the Court of Queen's Bench to grant or refuse leave to file such informations, and such leave will only be granted on motion made, grounded on proper affidavits, and in respect of misdemeanors of such magnitude or under such circumstances as, in the opinion of the court, call for its interference. After an information is filed, all the subsequent proceedings are, in general, the same as after an indictment found for a misdemeanor.

Persons committed for treason or felony who move in open court the first week of the term, or first day of the sessions of oyer and terminer or goal delivery, to be brought to trial, may, if not indicted some time in the next term or session after their commitment, be bailed by the attorney-general, or, the Queen's Bench, or justices of oyer and terminer or goal delivery, unless it appear that the witnesses for the Crown could not be produced the same term or sessions; and if not indicted and tried the second term or sessions after their commitment, and they are acquitted upon their trial, shall be discharged from imprisonment (31 Car. II. c. 2, s. 7). [INHALATIO CORPUS ACT, P. C.]

When the indictment is found, in cases of felony, the accused is bound to plead and try his cause, and, if the case be tried by the grand jury, to be brought to the bar and arraigned (which is the legal term for calling on a prisoner to answer to a charge of an indictable offence) as soon as convenient after such indictment is found; but in all cases of treason, except where the overt act is the assassination of the queen, the endangering of her life or person, or any attempt to injure her person (39 & 40 Geo. III. c. 38; 5 & 6 Vict. c. 51), and except the forgery of the great and other royal seals (7 & 8 Wm. III. c. 3, s. 18), the accused is to have a true copy of the indictment delivered to him ten days at the least before he is arraigned, and, at the same time, a list of the witnesses to be produced against him, and if indicted by any other than the grand jury or the Queen's Bench, a list of the petty jury; but if indicted in the Queen's Bench, the list of the petty jury may be delivered to him at any time after his arraignment, so as it be delivered ten days before the day of trial. (7 Geo. IV. c. 21, s. 11; 6 Geo. IV. c. 50, s. 21). If the accused plead, however, without claiming or having had delivered to him such copy of the indictment, he will be considered to have waived any objection on account of such non-delivery. In cases of misdemeanor, the accused is not bound to plead and try at the session at which the indictment is found, unless he has been in custody or out on bail, after which he is charged, twenty days at the least, before such session (30 Geo. III. & 1 Geo. IV. c. 4, s. 3), but may traverse the indictment, that is, postpone its determination to the next session. He must, however, before he is allowed to do so, appear personally in the
Queen's Bench, where he may appear by attorney and plead a petty indictment for a misdemeanor, not having been in custody nor out on bail, twenty days before the session at which he is so indicted, may also, at the subsequent session, traverse to the one following, unless he has been in custody or has been committed to await trial, to be tried within ten days before such subsequent session (6 Geo. III. c. 4, s. 5). If the accused, whether in case of felony or misdemeanor, be not in custody nor on bail when the indictment is to be tried, he may, without being indicted in a petit jury, by way of distinction from the grand jury. The ordinary courts having jurisdiction to try indictable offences are the Queen's Bench, Courts of Oyer and Terminer, Goal Delivery, and Courts of Quarter-Sessions of the peace of one county; and the superior Criminal Courts of the Counties Palatine; but Courts of Quarter-Sessions and Borough Courts have no jurisdiction with respect to treason or felony punishable by death of in any accused save upon a presentment or indictment in other offences (see 5 & 6 Vic. c. 38, s. 1). The trial is generally to be had in the county or district in which the offence was committed.

Upon the trial being called on, the jurors are to be sworn as they appear, to the number of twelve, unless they be otherwise directed. As to challenges, whether on the part of the Crown or the prisoner, and as to petty jurymen generally, see JURY, P. C. I may here be observed, however, that the right of peremptory challenge, i.e. of challenging at mere pleasure, without showing any cause, which exists in cases of treason and felony, is one of the common law liberties of the country, which the king cannot alienate without the advice and consent of two thirds of both branches of the legislature. In cases of felony, the power to challenge peremptorily to the number of thirty-five jurors in cases of treason, and to the number of thirty in cases of other felonies, is vested in the king, and exerciseable at the suit of the accused. When twelve jurors are procured free from exception, and have been sworn, or, if Quakers, Moravians, or Separatists, or persons who have been in religious communion with either, are retained by the Crown, they are not to be discharged for the non-appearance of the said jurors, unless there should be a sufficient cause, to which the defendant, the court, or counsel for the prosecution, may object, unless the defendant, by his counsel, shall, upon the trial, after the opening of the prosecution, and the giving of the questions, himself state a sufficient cause, other than the non-appearance of the said jurors, why they have been retained.

In cases of treason or felony, the prisoner may, before the opening of the prosecution, and the giving of the questions, be committed to the keepers of the house of correction, or to the officer of the county, as the law directs, in a manner to prevent his preparing, or engaging in, or procuring the preparation, or engaging in, or procuring the preparation, of any treasonable or felony documents, or to prevent his communicating with any persons, unless upon the authority of the grand jury, or of the court of quarter sessions; and he shall be committed without examination, unless upon the requisition of the grand jury, or of the court of quarter sessions, and the court shall be satisfied that the cause for which he is to be committed is such as is likely to endanger the public peace. The prisoner may, after he has been committed to the house of correction, or to the officer of the county, or to the keeper of the gaol, or to the sheriff, be brought before the court, to be remanded or discharged; and if the court shall think fit, they may order such finding to be recorded and the prisoner to be kept in strict custody until her Majesty's pleasure be known.

When, however, the plea of 'Not Guilty' has been pleaded, the trial is to be had before some court having juris-
When the jury have agreed upon their verdict, they signify that they are ready to deliver it; and on returning into court for that purpose, their names must be called over, and all twelve must be within hearing when it is given. The foreman of the jury is the person who is to deliver the verdict; and in cases of treason or felony, it can only be received in open court and in the presence of the prisoner: in cases of misdemeanor it may be delivered by the person charged, or by Guilty or Not Guilty, or may be a special one; and may be Guilty upon one count of an indictment, and Not Guilty upon another count, or Guilty as to part of the count, and Not Guilty as to the remainder. The offence is charged which includes a lesser crime of the same degree, and the latter only is proved; as where murder is charged and is set at large in open court, and an assault is a misdemeanor only. A special verdict is the finding of all the facts specially, where the jury doubt whether they constitute the offence in the indictment, and leaves the court to give judgment according to the legal effect of the facts so found.

Where upon the trial evidence is given of insanity at the time of committing the offence charged, and the jury acquit, they are required to find specially whether the accused was insane at the time of the commission of the offence, and whether he was acquitted on that account; and if they find in the affirmative, the court is to order him to be detained till the queen's pleasure he known; and she may give such order therefor as in like cases the queen has done, and of the same authority: (39 & 40 Geo. III. c. 94, s. 1; 2 & 4 Vist. c. 54, s. 3.) On a verdict of acquittal, or he is discharged by proclamation for want of prosecution, the prisoner is to be immediately set at large in open court, without the payment of any fine in respect of such discharge. (14 Geo. III. c. 20; 56 Geo. III. c. 50; 8 & 9 Vist. c. 114.)

When a verdict of guilt has been returned against a prisoner, the court, except in the case of prosecutions pending in the Queen's Bench, may proceed at once to pass sentence upon him, unless he allege some matter or thing sufficient in law to arrest or bar judgment. In prosecutions pending in the Queen's Bench, however, the prisoner is allowed four days for moving in arrest of judgment; or, in cases of misdemeanor, for a new trial or writ of certiorari. No. Also where the trial at any sittings or assizes is upon a record of the Queen's Bench, the judge before whom the verdict is taken may, under 11 Geo. IV. & 1 Wm. IV. c. 70, s. 9 (except where the prosecution is by information filed by leave of the Queen's Bench, or such cases of information filed by the attorney-general, as the government of the crown or crown's attorney-general, may order), pass sentence at once; but such sentence is not to have the force and effect of a judgment of that court, until after the expiration of six days after the commencemen of the ensuing term, during which time the prisoner may have a new trial, or to have the judgment amended. Except in the last-mentioned case of a trial at the sittings or assizes upon a record of the Queen's Bench, or where the offence of which the prisoner is convicted is a misdemeanor punishable by a simple fine, or where the Queen's Bench, after conviction for misdemeanor, thinks proper to dispense with his attendance, sentence cannot be pronounced against a prisoner unless he be present in court at the time.

Judgment may be arrested where the offender has received a pardon since his arraignment or after conviction becomes insane, or, having been convicted, though twenty-four hours after such conviction, denies that he is the person convicted (in which last case a jury is to be impanelled to try the fact), or for some defect apparent in any part of the record, as regards either the jurisdiction or the commission of the offence, or of the proceedings thereon, but not for any of the mere technical defects specified in 7 Geo. IV. c. 64, ss. 20 and 21. If the judgment he arrested, all the proceedings against him are to be set aside, and judgment of acquittal to be pronounced in his favour; but he may be prosecuted again for the offence of which he is so acquitted.

A new trial may be had on the application of the defendant in all cases of non-capital felonies pending in the Queen's Bench, where it appears to the court that the chargingbond is essential to justice; as, for instance, where the verdict is contrary to evidence or the directions of the judge, or evidence has been improperly refused. The recharge of Queen's Bench will also in its discretion, where a party is
acquitted of a misdemeanor on a prosecution pending in that court, allow a new trial, on the application of the prosecutor, if such acquittal has been obtained by any fraudulent means or practice, as where the party acquitted has kept back any of the prosecutor's witnesses, or neglected to give due notice of trial.

A writ of 

terri facies de novo, the effect of which is the same as granting a new trial, may be applied for, where, by reason of the error on the part of the jury, or of some uncertainty or ambiguity or other imperfection in their verdict, or of any other irregularity or defect in the proceedings or trial, appearing on the record, the proper effect of the first sentence has been frustrated, or the verdict has become void in law.

Neither new trials nor writs of 
terri facies de novo are granted in cases of treason or felony.

Where a new trial or writ of 
terri facies de novo is awarded, the parties stand in the state in which they were immediately before the first trial: the whole case is to be re-heard, and the first verdict cannot be used upon the new trial, or as evidence of any matter found by such verdict, or in argument.

After sentence pronounced against an offender, the judgment of the court may be falsified or reversed, either by plea without writ of error or by writ of error: by the former, for some matter not apparent upon the face of the record, as want of authority in the court by whom the judgment was pronounced, or for the same reason, for any material defect as are sufficient to arrest a judgment, and for any material defect in the judgment itself. Where the judgment has been pronounced by a court of oyer and terminer, gaol delivery, or quarter-sessions, or of a county petty sessions, it is to be brought in the court of Queen's Bench, and for that purpose the indictment and other proceedings thereon must be removed into that court by writ of certiorari (Certiorari, P. C. and C. S.): whereas it has been pronounced in the Queen's Bench, it is to be brought in the Exchequer Chamber, before the justices of the Common Pleas and barons of the Exchequer, from whose judgment a writ of error lies to the King's Bench.

In cases of treason and felony it is not in the discretion of the crown to grant or refuse a writ of error: in all other cases the fiat of the attorney-general must be first obtained, and this he ought to grant upon probable cause of error shown. When issued, the writ of error stays the execution of the judgment, where it has not been carried into effect during the time that such writ is pending, except that in cases of treason or felony the offender is not entitled to be liberated on bail. In cases of misdemeanor, however, where he is imprisoned under execution, or any fine has been levied, either in whole or in part in pursuance of the judgment, he is entitled to be discharged from imprisonment and to receive back any fine or penalty paid and taken on account of such termination of the Writ of Error. (6 & 9 Vict. c. 68, s. 1.)

If the judgment be falsified or reversed, such judgment and the execution thereupon, and all former proceedings, become therefore null and void, and any sentence pronounced against whom is so falsified or reversed, if living, and if dead, his heir or executor, is restored to all things which such person may have lost by such judgment and other proceedings, and stands in every respect as if such person had never been charged with the offence in respect of which such judgment was pronounced against him.

If, however, the execution only be erroneous, that only will be reversed; and if the judgment be reversed for some technical error merely, in the indictment or subsequent process, the party may be prosecuted again. If the judgment be confirmed, the prisoner is to be committed to undergo the remainder of his sentence.

Where there is nothing to arrest or bar a judgment, the execution of it may be prevented by a pardon received after sentence pronounced: but, without express words of restitution, where the offender forfeited by his conviction or attaintment, is thereby revoked in him; or, unless where the pardon is by act of parliament, it is the corruption of his blood removed, except as regards those of his blood born after the pardon, all the cases of the consequen-
ces of such previous corruption prevented.

In capital cases the execution of a judgment may also be suspended by a reprieve, either at the discretion of the Crown, or on a substantial justification created by law before the court. There are two instances however in which the court is bound to grant a reprieve, viz.: 1, where the offender, if a female, is pregnant; 2, where the offender becomes insane after judgment.

The statute also alleges that she is pregnant or the court have reason to suppose that she is so, a jury of twelve matrons is to be impannelled with all possible dispatch to try whether or not she be quick with child. In case they find at the trial that she is not quick with child, she is to remain in custody until she be delivered of a child or it is no longer possible in the course of nature that she should be so. After her delivery or where such delivery is no longer possible as before, the officer is to continue her in custody until she be delivered of a child, the court, at the expiration of the period for which it has respited her, proceeds to award execution against her. Where insanity is alleged, the court will reprove the pris-

Soner, if found to be a suspensory cause of ex officio inquiry, or if his insanity otherwise sufficiently appear.

Should the execution of a judgment be neither prevented nor suspended, or, having been suspended, should have ceased to be so, it is the duty of the court to arrest the execution and to issue a habeas corpus to the sheriff or other authorised person or his deputy. In capital cases, if the offender, after hanging, be taken down before he be dead, he is to be hanged again until he be dead. As regards the manner in which the various judgments which may be pronounced against offenders are to be executed, the subject is too extensive to be further treated of in an article like the present.

With respect to the expenses of prosecutions for indictable offences, the general provisions on the subject are contained in 7 Geo. IV. c. 64. According to these the court before which any person is prosecuted for felony or the following misdemeanors, such as: false accusation of felony; at-
tempts to commit felony; riots; receiving stolen property; assaults upon peace-officers in the execution of their duty, or upon persons acting in their aid; neglect or breach of duty by persons having any care or custody of the public revenue; illegal proceedings of officers to raise the rate of wages; obtaining property by false pretences or by undue exposure of the person; perjury and subornation of perjury, may, at the request of the prosecutor or any other person appearing on his or her own behalf to prosecute or give evidence, order payment of the costs and expenses incurred by the prosecutor in preferring the indictment, and also the reasonable expenses of the prosecutor and witnesses for the prosecution in attending before the grand jury and otherwise carrying on the prosecution; and also, whether a bill of indictment be preferred or not, may order the rea-
nons expenses incurred by any person by reason of attend-

ance on any such recognizance or subpœna (such attendance, where no indictment is preferred, appearing to be in bonâ fide obedience to the recognizance or subpœna), and, except in cases of misdemeanor, by reason of attending before the ex-

aming magistrate, and also, if the person shall attend before such magistrate in cases of misdemeanor, compensation for trouble and loss of time. Such payments are in general to be made out of the county rate.

It is the purpose of the statute to what principle the selection of the cases of misdemeanor in respect of which the court is empowered to award costs has been made. Other cases might with justice be included; and it may be a question whether, under other circumstances, there is not a case of a new conviction to be ex-
tended to the expenses of the prisoner's witnesses.

Offences punishable on Summary Conviction.

It would be inconsistent with the limits of the present article to give a detailed account of the various offences punishable on summary conviction, in number far exceeding those which are indictable. They relate, however, principally to ale and beer houses, apprentices, petty assaults, the Customs and Excise, distresses, drunkenness, friendly societies, gaming, hawkers and pedlars, highways, turnpike roads, petty thefts not amounting to larceny, malicious injuries to property, pawning and receiving stolen goods, vagrants, vagrants, warrants, and the numerous offences punishable under the Metropolitan Police Acts.

Summary proceedings, except in the case of attempts of the superior courts of justice (which some Courts have been immemorially used to punish by attachment), were wholly unknown to the common law. Their institution appears to have originated partly in the necessity for relieving the ordi-

nary tribunals from the immense burden which would otherwise have been cast upon them, owing to the mul-
tiplicity of new offences of a trivial kind which were yearly committed, doubtless at once arising from the nature of popu-

lation and civilization, and partly in the desire to do more speedy justice in the case of such trifling offences than it would have possibly been had they been made indictable. In the case of indictable offences a party cannot in general, as before
observed, be put upon his trial until a true bill has been found against him by a grand jury, and cannot be convicted except by the verdict of a petit jury: to have made all these minute offences indictable would have entailed upon the class of persons qualified to serve as jurors a frequency of attendance which would have been found to be most troublesome and harassing. Accordingly numerous acts of parliament have been passed to create new offences in the case of the peace or other persons the power to try parties accused of trifling offences without the intervention of a jury. The extension, however, of this mode of proceeding has been always resisted with a saner wisdom.

Where an offence punishable on summary conviction before a justice of the peace has been committed, or is suspected to have been committed, the general course of proceeding is as follows: An information is made but which need not be in writing unless directed to be so by the statute which creates the offence, to be laid before the justice authorized to take such information, who thereupon issues a summons to the party complained of, containing the substance of the charge, and giving him notice that at a certain time and place the hearing of the complaint against him will be proceeded with. If the party attend at the appointed time and place, and confess that he has committed the offence, the justice proceeds at once to convict him, and to impose the penalty assigned by the Act which creates the particular offence. If he attend, but deny the fact, or profess to be unacquainted with the matter accused of, the de- crust to be gone into for the purpose of showing that he has committed it. In the latter case, however, it must be first ascertained that he has been duly summoned. It appears that the word 'proceedings' must in all cases be upon oath, notwithstanding the Act creating the offence may authorize conviction on the examination of witnesses, without stating that the same is to be upon oath. So also such examination must be in the presence of the party complained of, where he appears; and generally, all rules applicable to the trial of indictable crimes may be considered as applying to the trial of offences punishable on summary conviction. Such rules are consistent with that mode of proceeding. If, after hearing the evidence, the justice is of opinion that the charge is not substantiated, the party accused is to be acquitted. If, on the other hand, he thinks that it is, he is to convict the offender and to impose upon him the assigned penalty. Upon conviction the justice usually issues his warrant to apprehend the offender, in cases where corporal punishment is to be inflicted upon him, or else to levy the penalty incurred, by distress and sale of his goods. This is the general mode of proceeding, as well where the conviction is required to be before two or more justices, as where it may be before a single justice of the peace, but for reasons of convenience to the several justices creating the offenses or inflicting the punishment. In some cases a power of appealing to the quarter-sessions is given to the party convicted. [Justice of the Peace, P.C.]

There are also cases of offences punishable on summary conviction before the Commissioners of Excise or persons other than justices of the peace, referred to be made to the statutes on the subject. The principles that hold true in the realm which have been consulted in the preparation of this article, are Hawkins's Pleas of the Crown; Blackstone's Commentaries; Russell, On Crimes and Misdemeanors; Chitty's Criminal Law; Starkie's Treatises On the Law of Evidence and On Criminal Pleading; Dickens's Guide to the Quarter-Sessions; by Tailourd; the 4th, 5th, 6th, 7th, and 8th Reports of the Criminal Law Commissioners; the Reports of the Commissioners for revising and consolidating the Criminal Law, on the subject of Penalties and Disabilities in regard to Religious Opinions; and Hilton On the Law of Convictions.

LEASE. A lease, or letting, is sometimes called a Demise (demisio). It is sometimes said that Lease is from the Latin locatio; but as the verb which corresponds to the noun Lease is Leas or Lest, which corresponds to the verb Leat, the verb Leat is akin to the French laisser and the German lassen.

He who lets land is called the Lesser, and he to whom land is let is called the Lessee.

There are various legal definitions of a lease. A lease has been defined to be a conveyance of lands or tenements from lessor to lessee for life, for years, or at will, generally in consideration of a rent or rent reserved. It is that lease by which the lessor conveys to the lessee the leasehold interest in the land demised, and the lessee holds under the condition of payment of the rent reserved. Under this definition, lease would denote a contract for a determinate period, and not a perpetual interest.

This mode of proceeding has been always resisted with a saner wisdom.

Where an offence punishable on summary conviction before a justice of the peace has been committed, or is suspected to have been committed, the general course of proceeding is as follows: An information is made but which need not be in writing unless directed to be so by the statute which creates the offence, to be laid before the justice authorized to take such information, who thereupon issues a summons to the party complained of, containing the substance of the charge, and giving him notice that at a certain time and place the hearing of the complaint against him will be proceeded with. LEASE. A lease, or letting, is sometimes called a Demise (demisio). It is sometimes said that Lease is from the Latin locatio; but as the verb which corresponds to the noun Lease is Leas or Lest, which corresponds to the verb Leat, the verb Leat is akin to the French laisser and the German lassen.

He who lets land is called the Lesser, and he to whom land is let is called the Lessee.

There are various legal definitions of a lease. A lease has been defined to be a conveyance of lands or tenements from lessor to lessee for life, for years, or at will, generally in consideration of a rent or rent reserved. It is that lease by which the lessor conveys to the lessee the leasehold interest in the land demised, and the lessee holds under the condition of payment of the rent reserved. Under this definition, lease would denote a contract for a determinate period, and not a perpetual interest.

To constitute a lease, it is necessary that the lessor's interest in the lands demised. If a man parts with all his interest in the lands or tenements, the conveyance is an assignment [Assignment, P.C.], and not a lease. The relation of the lessor and lessee is that of landlord and tenant.

The lease has a reversion in the lands which are demised, that is, after the expiration of the lease the land reverts to the lessor. The lessor, by virtue of this reversion, sovereignty, or lord's title, has the power of drawing on the land for the rent which is agreed on, and for the services which may be due by the terms of the lease; and fealty is always due to the lord.

The ordinary course of lease for a term of years, by which lease a rent, generally payable in money, at stated times, is reserved to the lessor. These stated times are usually quarterly periods.

The words used in a lease for the purpose of conveying that interest in the lands which constitutes a term of years are 'demise, grant, and to farm.' These words are derived from the law-Latin expressions 'demail, concess,' and ad firmam tradidit.' The word 'firma,' farm, is said to signify originally 'provisions,' and 'to farm let' does not properly signify to let to be farmed, in the modern sense of the term, but to let on the condition of a certain rent, being paid in farm, that is, in provisions. If this explanation is correct, a 'farmer' is one who had the use of lands on condition of paying a 'farm' or rent in provisions, such as corn and beans no longer than the time during which a man hires to cultivate upon the payment of a rent.

The interest which a man acquires in land by a lease for years is a term of years, or an estate for years. [Estate, P.C.]

The word lease is used in common language also to signify the estate or interest which the lessee acquires by the lease; but the word lease signifies properly the contract or conveyance by which the lessee acquires the interest in the lands.

The words 'demise,' &c., above mentioned, are the proper words to constitute a lease for years: but any words are sufficient, which clearly show 'the intent of the parties that the one shall divest himself of the possession (of the land), and the other come into it for a determinate time.' When the written contract is not intended to be a lease, but an agreement for a future lease, it is often difficult to determine whether the contract is not so expressed as to make it a lease.

At common law, it was necessary for the lessor to enter on the lands in order to make the lease complete, and no writing was necessary to make the lease complete, but for reasons of convenience to the several justices creating the offences or inflicting the punishment. In some cases a power of appealing to the quarter-sessions is given to the party convicted. [Justice of the Peace, P.C.]

There are also cases of offences punishable on summary conviction before the Commissioners of Excise or persons other than justices of the peace, referred to be made to the statutes on the subject. The principles that hold true in the realm which have been consulted in the preparation of this article, are Hawkins's Pleas of the Crown; Blackstone's Commentaries; Russell, On Crimes and Misdemeanors; Chitty's Criminal Law; Starkie's Treatises On the Law of Evidence and On Criminal Pleading; Dickens's Guide to the Quarter-Sessions; by Tailourd; the 4th, 5th, 6th, 7th, and 8th Reports of the Criminal Law Commissioners; the Reports of the Commissioners for revising and consolidating the Criminal Law, on the subject of Penalties and Disabilities in regard to Religious Opinions; and Hilton On the Law of Convictions.
tain, in order that the lease may be most beneficial to the landlord and the tenant, and by consequence to the public generally.

It is evident that the cultivation of subjects of leases are houses and buildings of all kinds, cultivable lands, and mines. Many persons who have not the complete ownership of houses and lands are enabled to grant leases under particular powers; and there are many statesmen who have particular classes of persons enabled or restrained, as to the granting of leases, such as Bishops, Deans and Chapters, and others. [Bennett, P. C.]

The kind of leases which we shall treat here are farming leases, which are granted by persons who have full power to grant them on such terms as they please. The particular form of such leases, as already intimated, is a matter that belongs to the subject of public economy, and it is almost beyond the province of direct legislation.

At present a great part of the land in England and Wales is held by large proprietors, and the number of landowners who cultivate their own estates is comparatively small. In many parts of the kingdom the number of small land-owners who cultivate their own farms has certainly been decreasing for some centuries, and they are probably fewer now than in former periods of our history. In England the great subdivision of land has been prevented by the form of government and the habits and feelings of those who have had the chief political power: and the great increase of wealth that has arisen out of the manufacturing and commercial industry of the country is deemed to prevent the subdivision of land and not to increase it. Those who acquire great wealth in England by manufactures and commerce generally lay out a large part of it in the purchase of land; for the ownership of land is deemed to be a man to found a family and to perpetuate it, to obtain social respect and consideration, and also political weight in the administration of public affairs. It facilitates his election to the House of Commons, and if he plays his part well, it may introduce him into due time to the House of Lords, and place him among the nobility of England.

Those who cannot acquire enough to give them political power, nor are anxious to acquire land, are a means of social distinction, and as a permanent investment which must continually rise in value. Thus there is a constant competition among the rich for the acquisition of land, which raises its price above its simple commercial value; and a man of moderate means does not find it easy to purchase land in small quantities and on such terms as will enable him to obtain a proper remuneration for the cultivation of it.

The great mass of the cultivators in England are now tenant farmers, who hold their land either by leases for years or by such agreements as amount to a tenancy from year to year only; and there is the kind of competition among them to obtain land for their own use, that enables him to obtain land by purchase. The consequence is that more rent is often paid for land than it is worth: a consequence of the limited amount of land and of the number of competitors for it. The rent is sometimes increased in consequence, but it enables the landlord to impose conditions which are unfavourable to the tenant and to agriculture, and finally to himself.

Several things are essential to the good cultivation of land, whether it is held by lease or is the property of the cultivator. These essentials are, a knowledge of the best modes of husbandry, adequate capital, and a market in which the farmer may fairly buy and sell all that he wants. Now, in the present state of agriculture in this country, not one of these three conditions exists in the degree which is necessary to ensure good cultivation. The greater part of the land in England, as well as in the colonies, is cultivated under leases or a tenancy from year to year; and the covenants in the leases are often such as to be an insuperable obstacle to good agriculture. The condition then of the tenant farmer, as determined by his lease, is something that should be considered.

Many landholders have several objects in view in letting their lands besides the getting of rent. One of these objects is to maintain their political weight by commanding the votes of the tenant. This is mainly effected by leasing their lands for determinate periods, such as seven, fourteen, or twenty-one years; but by making them very nearly tenants at will, or liable to quit at six months notice, which he grants for his tenant. He may rent a piece of land to cultivate, out of which he may be turned on a short notice, will not be an independent voter. Nor can the landlord expect to have a good tenant who will improve his land and a political tool at the same time. The uner-

The improvements which would follow from a good system of leasing would be the abolition of the evils which now exist in consequence of uncertain tenure and of bad leases. It is affirmed by the best authorities that the amount of capital which is now applied to the cultivation of the land in England is much less than it would be if there were not sufficient capital to improve their lands, nor the necessary skill and enterprise; and it is maintained that these evils are mainly owing to the want of a sufficient security of tenure or the way in which they are conducted, to the abnormal restrictions with which many of them abound.

It has been said, and truly enough, that there is no advantage to the landlord in granting a lease to bad cultivators, and that there are many such. Such a lease would not indeed be any advantage to the farmer himself or the community in general; but he who has land to let, and will let it on terms that are mutually profitable to the landlord and the tenant, will be much more likely than a farmer who has no capital and skill than he who gives the farmer an uncertain tenure or binds him in the fetters of a bad lease.

The preservation of the game and the enjoyment of the pleasures of the chase, or of the profits derived from the wild animals, is another object which some landlords secure by their leases with as much minuteness and strictness as they do their rent. [Game Laws, F. C. S.] Thus, in addition to getting a rent from the tenant, they may command the votes of his tenant and secure his game. With reference to these objects and certain other imaginary advantages which he purposes to secure by directing the mode of cultivation, the tenant is often bound by numerous restrictions, penalties, and feudal services, which no care on the part of the farmer can prevent him from breaking in some particular, and which no man of capital, skill, and independence from the feudal system can prevent from being imposed. The leases have been printed and circulated. One of them appeared in the 'Leicester Chronicle' for June 28, 1845. This lease prescribes a mode of cultivation which is absolutely inconsistent with good farming. The landlord in such a case directs the tenant how he must cultivate the land. If the directions which the landlord gives comprehended the best modes of cultivation, they would be unnecessary if he had a good tenant, and they would not be observed by a bad one.

A good tenant with sufficient capital will farm the land according to the system best adapted for the land, and he will be ready to avail himself of all improvements. The good tenant, whether he is capital or not, will act well simply because he is prevented from doing some things and bound to do others; for farming, like other matters, consists not only in doing a thing, but in doing it well. These conditions and restrictions, if enforced at all, can only be enforced by constant supervision, and must be an endless source of trouble and dispute.

But leasing farming leases are often copies of old leases, made in other days, and are unsuited to the present state of agriculture. The things which they require not to be done and those which they require to be done, are often inconsistent with each other. The tenant must cultivate the land and let him use the land from yielding that amount of produce which it would yield under the best system, not only without thereby being impoverished, but with the certainty of permanent improvement. Ignorance on the side of the landlord of his true
interest is one of the reasons why many of these absurd leases still exist.

There can be no principle in the letting of land, if the object is simply to secure the best rent to the landlord and the permanent improvement of the land, which makes it different from the letting of any other piece of property.

The good farmer hires land to cultivate, with the hope of deriving profit from the application of his skill and capital. He does not want the advice and direction of another man; he trusts to himself. The object of the landlord is to get as much rent as his land is worth, and to secure it against deterioration during the tenant's occupation. The terms of the lease, then, should simply be, the payment of rent, and the observance of such provisions as are found by experience and known to practical agriculturists to be necessary to secure the permanent value of the landlord's land. It is admitted by all reasonable people that the landlord should have ample security by the lease for his land being given up to him at the end of the lease in as good condition as he gave it to the tenant. The tenant wants no directions from the landlord, and no conditions in his favour, beyond the simple condition of being allowed to cultivate the land in the best way that he can for his own profit during a period sufficiently long to secure him a return for his outlay; and he acknowledges that himself, submits to all conditions in favour of the landlord, which are not inconsistent with his free cultivation, and which shall secure the permanent value of the landlord's property.

Perhaps many landlords who now grant hard leases would agree to less on these principles, and in this way they would insist on many conditions as necessary to secure their permanent interest, which a good farmer would object to, as not necessary for that purpose, and also as inconsistent with his freedom of action.

The framing of such a lease as we have described in general terms, must be the joint work of intelligent and liberal landlords and of good tenant farmers. It may require some time, some more or less retrenchments and modifications from many quarters before such a lease is got into the best form. But it is an object worth the consideration of all persons interested in the cultivation of the land, and the attempt has been made already. Mr. Cobden, who is well acquainted with the Vale of Evesham Agricultural Association, which has been conducted with the purposes of obtaining the suggestions of competent persons.

It has been said that some farmers do not care for having long leases; they are willing to go on as they have done. But it can be shown that there is a number of intelligent farmers with capital who prefer a yearly tenure to a lease of reasonable length. Besides, some of these agreements for a tenancy from year to year contain restrictions almost as numerous and absurd as those in leases for a term of years.

If there are farmers who prefer dependence to the independence of their property, who prefer a landlord to a free farmer and landlord, these are not the men to improve our agriculture; these are the men with little capital, and less skill, who have no hopes of improving their condition, who rely on the temporary employment of their land, and who are taught that they and their labour must be protected from foreign competition. The intelligent farmer with capital seeks no protection against the foreigner, and wants no indulgence from his landlord. He is ready to give, and he would be compelled by compulsion to give, to the landlord the full value for the use of his land, and he would ask for no more than the liberty of cultivating it in the best way.

Before, however, a good farmer could enter on the land with full confidence, he would have one favour to ask of his landlord; and that would be, not to protect him. If he were defeated by being left in the lurch in his business, the farmer in one part of the kingdom wants something that he does not produce: but it is produced in another part of the kingdom. Both parts are protected in what they produce, that ease and that certainty which shall full the pockets of the farmers by strengthening in what he buys in order that the other may be protected. Thus the legislature interferes with the prices of things. They do impose a tax on foreign produce that comes into the kingdom simply with the view of getting revenue from it; they profess to interfere in order to keep up the prices of certain commodities that are produced in the kingdom. They profess to regulate within certain limits the prices for which the farmer must buy and sell his agricultural produce; they profess to do it; but everybody knows that the corn laws knows that they cannot do it, and never have succeeded in the attempt. But they have succeeded in breeding up a race of farmers, and of landlords too, who believe that their true interest is best secured by a constantly attempting to raise the prices of all agricultural produce, both that which a farmer buys and that which he sells. As matters stand now, we have by his lease directs his tenant how to cultivate, and at the same time reserves the power of walking over his ground when he pleases to kill the game which the farmer must not kill, but which he must feed; a tenant with deficient capital and insufficient skill, and the shackles of a restrictive lease, or an agreement for a lease which constitutes a tenancy from year to year, and a legislature which interferes with prices and shunts the farmer as well as others from buying in the cheapest market whatever agricultural produce he does not raise himself. Then there is a cry of agricultural distress, and when the ablest man in the House of Commons asks for a committee of inquiry into the condition of the farmers, the tenant, those who complain of the distress will not have the inquiry.

It has been shown [Agriculture, P. C. S.] that all duties levied on agricultural produce that is brought into these kingdom, are productive of distress, however much the farmer may profit. He who disputes this proposition is inaccessible to the cogent power of reason. He who admits it, and contends for the system, must contend that on the whole it does more good than harm. But it is a system continually creating agricultural distress, so that the system does not promote agricultural distress. Those who have handled the subject best attempt to prove, and we believe that they have proved, that the system causes no distress. But it is the chief obstacle to improved cultivation of the land, the granting of good leases, the employment of fresh capital in the cultivation of the land, and the employment of agricultural labour. All these are the causes urged by the House of Commons (1845), in a speech, when he moved for a select committee to inquire into the extent and cause of the alleged existing agricultural distress, and into the effects of legislative protection upon the interests of landowners, farmers, and farm-labourers—a speech unequalled for perspicacity of statement, practical knowledge of the subject, clearness of expression, and sound argumentation; a speech which would place Mr. Cobden, if he had not already earned that distinction, among the very few men who have views at once comprehensive and sound enough to entitle them to the honour of directing the affairs of industrious people.

The covenant is a fact, however few they may be, occasional difficulty and dispute upon the expiration of the tenancy. The landlord may often claim more than his due, and the tenant may be disposed to do less. These difficulties are not only serious in themselves, but all the more so in the case of the case of leases which are in the opinion of a House of Commons (1845) to be a vestige of the old feudal system. The old feudal system continued in the case of leaseholds: the system of leasing and occupying land with the expectation of being able to purchase it, was abolished in 1740, but it is still in existence and continues in the case of leaseholds. It has been suggested that in the case of dwelling-houses in large towns like London, some easy mode of finally settling such disputes might be established. In such cases, the evidence of owners is the evidence on which a jury must give their verdict in case of legal proceedings; and it would be quite as satisfactory to all parties, if the evidence that is submitted to a jury, for their judgment, which is to be used against the farmer, is given to the farmer in some uniform manner, and whose decision should be final.

In 1845 an act was passed (8 & 9 Vict. c. 124) entitled "An Act to facilitate the settlement of controversies arising in respect of a lease, or to vest the right to the landlord in a lease, without any further proceedings. The object is to substitute abbreviated forms for those now in use, and it is provided that in taxing any bill for preparing and executing any deed under the act, the tax officer, in estimating the proper duty, shall be charged a duty to the extent of length of such deed, but only the skill and labour employed, and the responsibility incurred in the preparation thereof. It is enacted in section 4, 'That any deed or part of a deed which is signed and sealed by any person other than the parties thereto, so far as the rules of law and equity will permit, if this act had not been made.' There are schedules to the act.
one of which gives, in column 1, short forms of expression
which may be used in place of the ordinary expressions in
leather, which are contained in column 2; and it is enacted
by section 1, 'That whenever any party to any deed made
according to the preceding schedule be bound to perform
the act, or to any other deed which shall be expressed to be made
in pursuance of this act, shall employ in such deed respectively
any of the forms of words contained in column 1 of the
schedule to the act, and shall be considered as if the same
were annexed to the same deed as is annexed to the
form of words employed by such party; but it shall
not be necessary in any such deed to insert any such number.
This act does not extend to Scotland. The amount of words
saved by this act is not sufficient in compensation for the dif-
culties that may arise from persons using the abbreviated form
in cases where they may not intend them to have the full
meaning which this act gives to them. He who wishes to
secure himself either as landlord or tenant by suitable cove-
nants will do better to express his meaning at full length,
without availing himself of the abbreviations which this
act invites him to use.

Legal terms require either an ad valorem stamp or the
common deed stamp, without which the instrument cannot be
given in evidence. Leases for a term determinable on a life
or lives not exceeding three, and the leases of all ecclesiastical
corporations or bodies, are not to exceed twenty-one years, are
exempted from duty. There is also a stamp duty on-agreements for leases. This
is one of the many modes of taxation.

LEATHER. An account of the chemical processes by which
the skins of animals are converted into leather is given
under TANNING, P. C. p. 57; and under LEATHER, P. C.
p. 55. The various kinds and stages of the leather-making
process are described and illustrated. The present article treats of the subject
of currying and leather-dressing.

In an interesting lecture 'On Tanning and Leather-dress-
ing,' read by Mr. Arthur Aikin before the Society of Arts
in 1830, and published in the fifth volume of the Society's
Transactions, pp. 192-214, is a notice of the principal kinds
of skin which are converted into leather, and of the chief
uses to which each kind is applied. From this we may
conclude a few particulars illustrative of the wide range of
the leather manufacture, from which it will be seen that the
processes followed in its different departments must be exceed-
ingly various. The more remarkable of these processes and the skins, Mr. Aikin observes that among those of oxen, tech-
ically known as hides, those supplied by bulls are thicker,
stronger, and coarser in the grain than those of cows; while the
leather from castrated or castrating bulls are intermediate be-
tween those of the bull and the cow. He states that the
thickest and most substantial leather now in use is that made
from the hides of the half-wild cattle of South America. Such
leather is employed for the soles of boots and shoes; for most
parts of harness and saddlery; for making leather trunks,
buckets, hose for fire-engines, and pump-valves; for the thick
belts used in military accoutrements; and for the gloves of
cavalry. The thick buff-leather formerly used as armour, and
which was pistol-proof, and would resist the edge of a sword,
was made from the hide of the bear, or wild bull of Poland,
Hungary, and the middle and southern provinces of Russia;
the animal itself being called buffa, whence the common name of
the leather made from its hide. The skins of calves
though thinner than those of cows, are thicker than most other
kinds of skin, and are extensively used for the leather. They are
taved (Tanning, P. C. p. 40) for the use of workmen, and
are tanned and_curried for the upper leathrs of boots and
shoes. Aikin states that it was formerly customary, in the sound-
ground, and the middle and southern provinces of Russia.

The leather is then tanned, usually in wads of clay, and
that the celebrated Limnerock gloves were made of this; it is
usually fine and delicate skins of the unicorn calves. The
practice is however, it adds, now almost discontinued, so that
the trade in this kind of leather is entirely superseded by other
kinds, and the saving of which are not now to depend upon peculiarities in the
material, but upon the quality of the skin than upon its original quality.

Leather, which is most commonly of home growth, although Aikin refers to
a considerable supply as coming from the Cape of Good Hope,
vary much in quality. A long fleece, observes our au-
thority, 'always indicates a thin skin; much of the jelly laid
up in that organ being, perhaps, the material from which the
leather is made; and a thin leather is always one which is
distinctive remark that 'as soon as a sheep has been sheared the air
comes in contact with the cuticle, checks the perspiration
and expenditure of the skin, and allows the jelly to accumulate;
which it does so rapidly that it is of wool. sheep enclosures
with long fleeces are driven up to London from the distance of a
few days' journey, and if part of them are slaughtered immediately on their arrival, and the remainder are
slaughtered by degrees, and the skin of the latter will be
twice as thick as that of the former.' When simply
shaved, sheepkins are employed for inferior bookbinding,
for leathering bellows, and for various other purposes for which a
cheap leather is required. All the skin-leather, as it is
termed, which is used for whip-hashes, base, aiptous, &c., is
of sheepskin; as are also the cheaper kinds of soth-leather, of
which brushes, gloves, under-waistcoats, and other articles of
dress are made. Mock or imitation morocco, and most of
the other coloured and dyed leathers used for women's and
children's shoes, carriage-linings, and the covering of stools, chairs,
sofas, writing-tables, &c. are also made of sheepskin. Lambs-
skins are often used, especially white or coloured, as such
of goats and kids supply the best qualities of light
leather, the former being the material of the best morocco, all
other, while kid leather, both white and coloured, affords
many of the finest qualities for shoes, boots, leggings, and
shoeskins, are used for making gloves, as moccasins,
leather-dressed. Aikin states that the
Shamoyed leather breeches were formerly very much used,
especially in the army, and that English shamoyed leather was
in high repute, it was used not only in the clothing of our
own army, but by the cavalry of that nation, and of
most of the other German states. During the
Peninsular war it was discovered that the leather of the British cavalry
was seriously affected in wet weather by their leather breeches,
which, being made of genuine skins, contracted, and
chilled the men, and rendered them liable to rheumatism
and other diseases. Woolen cloth was accordingly substituted for
shamoyed leather in this article of dress, first in the
British, and subsequently in the Austrian and Prussian
armies, and this change has effected a great decline in this
branch of the leather manufacture.

Horse-hides, which, con-
sidering their size, are thin, are tanned and curried, and
are used by the harness-maker, especially for collars; and occa-
sionally, when pared thin, for the upper leathers of liders' walking shoes. Dog-skins are thick and tough, and make
ecellent leather; but Aikin observes that as the supply is
entirely from the dog of the smaller kind and have been
for several years as to be nearly extinct, dog-skin leather has been in a
great measure superseded, as a material for dress shoes, by
horse leather and by tanned rat-skins. Seal-skins produce a
leather which is inferior to the heated leather, but
and hag-skins afford a thin but dense leather, which is used
exclusively for covering the seats of saddles. 'It comes,
Aikin states, from Scotland and Yorkshire, for though hogs
are abundant in every part of the country, the general custom
of cooking pork with the skin greatly restricts the supply.'

Referring to TANNING, P. C., for an account of the processes
by which hides and skins are converted into leather by tan-
ing, tawing, or shaving, we may here notice some impor-
tant observations on the subject quoted by Dr. Ure, in the
'Supplement' to his Dictionary of Arts ('art, Leather,'
p. 147), from a communication made by Mr. John Lee
to the Franklin Institute, in February, 1814. Mr. Lee expresses
his belief that much of the original gelatine of the hides
is never combined with the tannin, but is wasted; for he thinks
that 100 lbs. of perfectly dry hide, which has broken
and removed all the fur, after being kept in
for several years, and tanned, cost not more than
180 lbs. of leather. 'He believes the usual mode of preparing
the hides for actual tanning, called the liming and baking;
or unliming and cleansing, to be a waste of leather;
and that the upper layers of leather are usually done either by steep-
ing the hides in a solution of lime, or by placing them in a
close heated chamber until the epidermis is loosened by
E japonica putrefaction. Sometimes however this
is performed by a process in which the hides are kept
in Germany, and consists in laying the hides in a
jake or pile, covered with tan, to produce fermentative heat. All of these plans, but
especially the two latter, are said to be injurious to the hides.

The term tanning, as used in connexion with the process analogous to that described in Tanning under the term raising, consists in steeping the hides in a solution of pigeon's dung, containing, Mr. Lee says, urates of ammonia, with the addition of the most powerful compounding of ammonia and lime, with urate of ammonia, and very

fermentable animal matter.

Dry hides are often softened by the operation of the fulling-stocks, which has the effect of softening the leather, for which purpose this is done, care must be taken that the fulling or beating be not too violent, in which case it would make the hide too limber and thin. Mr. Lee conceives that the lining process is injurious to the hair of the skin; and it appears that leather which has been highly limed is loose in texture, weighs light, and wears out quickly.

The subsequent fermentation in the tanning process aggravates the evil ascribed to the lining. This evil is to be avoided in a process which has been adopted in New York, Maine, New Hampshire, and some parts of Philadelp

...
tallow is then laid on with a soft brush, after which the surface is rubbed with a smoothing-glass. The finishing gloss is given by a little thin size laid on with a sponge, after applying which the skin is laid up to dry and incorporate, according to the case. And a lump of polish is laid lightly over the surface. 'The skin is thus,' he adds, 'completely finished for the consumer; and leather so dressed is found superior in appearance and durability to any other method.

Leather is occasionally dressed 'black on the grain,' or having the hair or grain instead of the flesh side coloured. The currying operations in each case are similar to those above, but in the blacking the flesh side is applied to the skin immediately after scoring, by rubbing it with a solution of copperas. A brush dipped in stale urine is then passed over the surface, and an iron slicker is used to make the grain come out as fine as possible. It is then studded with oil, and, when dry, seasoned, or rubbed over with a brush dipped in copperas-water, on the grain, it is perfectly black; after which it is alched with a g r i t t o n e , to remove any wrinkles and smooth down the coarse grain. The grain is finally raised by repeatedly rubbing over the surface, in different directions, with the pommel or grainboarding.

One of the most singular operations in the working of leather, which may be noticed here as an illustration of the peculiar properties of the material, and of the power of the currier over it, is the mode of covering the roofs and upper panels of coach-bodies, of which an interesting description is given in the 'Penny Magazine,' 1835, 'A Day at a Coach-factory.' In this operation, which is only performed upon the higher class of carriages, the whole of the roof and upper part of the front, back, and sides, is covered with a skin, cut into two pieces, the front-piece from the front of the coach, and the other side, and so on, but made to fit closely in every part to the woodwork without any joints or divisions, and without showing any folds or wrinkles. 'To accomplish this apparently impossible effect,' he adds, 'the skin is very large and of sound quality, and, in every part, as close to the paper referred to, 'first thoroughly moistened throughout and thrown over the top of the coach, the edges hanging down on all sides. The currier then rubs or brushes it over all the roof, the back and sides, and even in every part. He next proceeds to one of the sides, and in like manner rubs and smooths the leather till all irregularities disappear. 'The leather is in that soft and pliable state that it will yield to the movement of the tools, and enable the workman to fit it to every part of the coach with perfect closeness. 'A little consideration,' observes the writer, 'must show that a superfluous fold of leather will occur at each corner; yet by working it towards a central point at the back or front, the currier succeeds in raising, or pressing out all irregularities, and in producing a surface sufficiently flat and smooth for the subsequent operations of the painter.' The edge of the leather is cut off triangularly, thus dividing what divides the upper from the lower panels. In many cases modern carriages have the roof only covered with leather, which is laid flat, nailed, and left to shrivel.

Japonised leather of various kinds is also in use, in shoe-making, harness-making, and for various other purposes. Mr. Adams, in his treatise on 'English Pleasure-Carriages' (p. 69), states that what is ordinarily termed 'painted leather' is covered with a ordinarily transparent 'patent leather,' which gives a surface like polished glass, impermeable to water; and that hides prepared in a more perfectly elastic mode of japanning, which will permit folding without cracking the surface, are called 'enamelled leather.' Such leather is usually made black, but may be produced of any required colours. 'All this japanned leather,' he observes, 'has the Japan annealed, something in the same mode as the hides laid before; but the latter are subjected to the heat of an oven at a particular temperature during several hours.' Boots and shoes are sometimes made of thin enamelled leather, and they possess the advantage of never requiring much oiling, being sufficient to remove any dirt which impairs their gloss.

Of the preparation of Morocco and some other kinds of leather which present peculiar features in their manufacture, a few words may not be out of place. From the account of the manufacture of Russian leather, called by the Russians themselves jucen, which is usually dyed red with the aromatic saunders-wood, and is celebrated for being free from any of the above-mentioned defects, it is not only being proof against insects, but repelling them by its colour, so as to preserve books in the binding of which it is used. The skins are freed from the hair or fleece by steeping them in an ash-lye, then rinsed, fulled, and fermented in a proper steep, after having been washed in hot water, for a week or more, to raise or open their pores. They are then cleaned, by working them over the horse, on both sides. They are then soaked for about twenty-four hours, and then laid in a paste of eye-dirt, in the proportion of 38 lbs. of flour to 200 skins, enriched with leaven. The skins, when taken out of the bath, are left in tubs for fifteen days, and then washed. Being thus prepared for the action of the astrigent or blackening juice, they are immersed in a boiler containing a hot decoction (just sufficiently cooled to avoid injuring the animal fibres) of willow bark (that of the salix cinerea and salix caule), in which they are laid, for one hour, and then left to soak fifteen minutes. This manipulation is repeated twice a day for a week, after which the tanning infusion is renewed, and the process is repeated on the same skins for another week, after which they are exposed to the air to dry, dyed, and cured with the empyreumatic oil of the bark of the birch-tree, for the preparation of which Dr. Ure, whose account we have followed, gives full directions (Dict. of Arts, p. 779). This oil, to which the leather is indebted for its peculiarities, is applied only to the flesh side, and care must be taken not to prevent its passing through and staining the grain side. Chemovet, having investigated the odorous matter of this oil, has given it the name of cumin oil.

Shagreen, a peculiar kind of leather, or rather of prepared skin, formerly much used for the covers of watch-cases, mathematical-instrument cases, &c., is briefly noticed under that of the leather, to which it belongs, and we also accordingly agree with those of Aikin and some other authorities. From Aikin's lecture, referred to at the commencement of this article, and Hebert's 'Engineer's and Mechanic's Dictionary,' the following account of shagreen or shagreen skin, when being soaked in water and scraped to remove the hair, is further scraped until it does not exceed a wetted hog's bladder in thickness. It is then, while wet and soft, stretched upon a frame, and the strips are attached with horsehair and round seeds of the albus, or goosefoot (chenopodium album). A felt being laid over these, they are trodden deeply into the soft yielding skin, after which the frames are so situated in the shoes, that as the dress is finished, the skin may be shaken out without violence, leaving the skin in a hard horny state, covered with deep indentations. The surface is then rasped or rubbed down with iron tools, nearly to the bottom of the holes or indentations, the skin being during this operation, laid upon a block covered with wool. The skins are then softened, first with water, and then with a warm alkaline ley, and are heaped, while warm and wet, upon each other; and by this softening the depressed parts of the skin rise to their former elevation, forming prominent points wherever depressions had been made by the seeds. The skins are then salted and dyed, after which, according to Hebert, they are finished, but the description of the process is rather short, but very clear, and the finish produced is perfectly hard and smooth. The skins, when to be finished, are laid in a box of shells, and are covered with a mixture of a beautiful green dye is given by soaking the inner or flesh side of the skin with a saturated solution of sal-ammoniac, strewing it over with copper-flings, rolling it up with the flesh side inward, and pressing it with the weight of a box containing about twenty-four hours; in which time the sal-ammoniac dissolves enough of the copper to penetrate the skin with an agreeable sea-green colour: this is repeated a second time, in order to give the colour more body. 'Blue shagreen,' he adds, 'is dyed with indigo, dissolved in an impure soda by means of lime and honey. Black shagreen is dyed with galls and vitriol.' Aikin, evidently referring to a more ornamental variety of shagreen, instead of giving the above directions for dyeing, says that the skin is stained superficially only, of a green colour, with copper-flings and sal-ammoniac, and then dyed; and that the shagreen is then rubbed down to a perfect light, when the points that were prominent, being deprived of their superficial colouring, appear as white dots scattered over, and gradually melting into a green ground. The shagreen thus produced is susceptible of a high polish, and is both beautiful and durable. Great difficulties present themselves in the way of any application of machinery to the dressing of leather, in consequence of the need of a certain degree of leverage, to obtain an action which will work only on different kinds of leather, of different parts of the same skin; yet the great amount of time and manual labour involved in the polishing and graining of morocco and other ornamental leathers, has induced some ingenious men to invent machinery to do this.

Hebert contrived what he describes as the earliest machine for the finishing of leather, for which he obtained a patent, and which had been in use about twenty-five years.
when he published his 'Engineer's and Mechanic's Encyclopedia,' in 1839. This machine consists essentially of a stiff circular frame or wheel, eight feet in diameter, revolving horizontally upon a vertical axis, and carrying, on the under side of its periphery, a series of circular polishers or graters, which are capable of being applied or removed as needed for the work to be performed. These, as the apparatus revolves, pass over a series of eight tables, circularly arranged, and mounted upon elastic bearers. The skis to be operated upon are laid upon these tables, and the man who lays the skin smoothly on it, and moves it about from time to time, so as to bring every part in succession under the revolving grater, but as no edge of the knife would come in contact with the surface of the ski, each table is further supported by a lever, to one end of which is attached a trestle, on which the workman can place one or both feet. The effect of this arrangement is that while both hands are left at liberty to manage the ski, a greater or less pressure can be given at pleasure by the operator, while, by entirely removing his foot from the trestle, the table may be caused to fall just clear of the rubbers or polishers, so that the skin will not be touched at all by them. That portion of the surface of the table upon which the rubbers operate is formed of brass, and adjusted to a shape, and its angle, so as to be levelled off to prevent the rubbers from striking the skin injuriously as they come in contact with it. To obviate the comparatively trifling defect arising from the circular instead of rectilinear motion of the machinery, Mr. Hebert contrived a similar machine, which is also described by Hebert, in which the rubbers were attached to the periphery of a vertical wheel about thirty inches in diameter, and the skin was passed through a series of revolving rubbers; but the serious practical objections to such a contrivance are evident. Hebert did not know whether it had been brought to work with advantage or not, and it is quite possible that even thin skins may be divided into two thicknesses, each of which is capable of being dressed as a perfect skin, have called forth much ingenuity of contrivance. Illustrated descriptions of several such machines as well as the patent or any information given by any one mentioned by him, in Dr. Ure's 'Supplement.' Before such machines were introduced the reduction of thickness necessary to bring many of the finer kinds of leather to the requisite tension was effected solely, as it still is partially, by paring or shaving the flesh side with a knife worked by hand, an operation occupying much time, and requiring great nicety to prevent cutting through the skin. The part shaved off, also, being necessarily in small pieces, was only available for the making of glue. By the use of a machine the best portion of the leather, that with the grain side, is cut of a much more uniform thickness than it was before; the removed portion is taken off in a more useful form; and the whole operation is conducted more rapidly. Hebert states that, to show the capabilities of a splitting-machine long used by him, he covered a cowhide, which he had been at pains to split sheep-skins into three equal parts, one of which, that on the grain-side, might be used as leather, the middle portion converted into parchment, and the slice on the flesh side, being unequal in thickness, and therefore unfit for any better use, being used for glue-making. In this machine, which is also represented and described in No. 635 of the 'Penny Magazine,' the skin is drawn between two revolving rollers, and presented, as it emerges from their grasp, to the edge of a long and very sharp knife, which is kept continually moving a little backwards and forwards with great velocity. As a skin of unequal thickness could not be grasped in the proper manner upon the rollers between them, the upper roller, instead of being solid, is composed of a number of circular discs or rings of metal, about half an inch thick, slipped on to an axis rather smaller than the holes in their centres. These axes may be termed a planetary axis, which is a rod passing loosely through holes in the whole series of discs between their centres and their circumference, and so connected with the axis by its ends that they are free to move by the aid of the plane edges of the disc. The roller is enabled to adapt its surface to that of the skin, which is everywhere pressed with an equal force, due to the weight of the discs of which the upper roller is composed. It is stated that the leather is produced in about two minutes, during which time the knife makes from two to three thousand vibratory motions to and fro. This machine, according to

Hebert, in the invention, of Lieutenant H. P. C. W. In the machine described by Dr. Ure, and in some others, the knife is stationary, and the cutting is occasioned by the application of a steady force by which the skin is drawn against its cutting edge; and in Duxbury's patent skin-splitting machine the axis of the whole, which is horizontal, revolves in the rim of the whole parallel to its axis, and lies very nearly in the same plane with its face, and which, instead of cutting, is merely a cylindrical revolving cylinder, so hollowed as to present a concavity perfectly tallying with the curvature of the periphery of the disc. As therefore the drum revolves, it brings the skin, which is confined closely to its concave surface by a contrivance somewhat resembling the upper roller in the machine above described, in contact with the edge of the revolving knife, which cuts by a continuous and uniform movement, instead of a sawing action backwards and forwards. The extreme nicety required to fix the concavity of the feeding-roller to the edge of the circular knife, and to keep the knife or cutter itself perfectly true in a shape, and its form to be the chief objections to this ingenious contrivance.

We may close this article by referring to some practical remarks on the choice or purchase of leather in the second part of Mr. Devlin's 'Knight's series of 'Guides to Trade,' premising that the subject of his complaint in reference to English leather is likely to be, if it be not already, materially affected by the very great reductions in the price of manufactured leather, especially of the better classes, made by the English manufacturers under the tariff of 1842, and the still further reductions proposed in the government measure now (February, 1846) under discussion. After some remarks tending to prove a great deficiency in the quality and quantity of leather among shoemakers, but even among tanners and curriers themselves, respecting the qualities of leather, Mr. Devlin quotes from a pamphlet printed by himself for circulation among the London manufacturers of leather, to the Board of Trade, in France, as it affects the interests of the British Manufacturer, the following remarks:— 'If we look,' he says, 'to the nature of our leather, to almost every description of our leather, excepting that used for the soles, we shall find the article not so good—so intrinsically good—as that which the French boot and shoemaker can purchase; and what is more pertinent to the matter, is, that formerly it was not so; when a greater time and a more honest consideration were paid by both tanner and currier to the production of the highest degree of wholesomeness, surpassing beauty of grain, a perfect blackness and whiteness, a decided firmness, a decided polish, as mere thickness being the only necessary perfection.' 'But what,' he adds, 'can the manufacturer do? He gets his work done rapidly, and, in consequence, cheaply; and being, as he is, protected from the full effects of French and other competition by our manufactures being increased, and, likewise, through this circumstance, feeling himself secure of the commands of the home boot and shoemaker, he goes on in his cupidity, hurrying and driving through as much business as he can, safe in his own interests, and never pestered, hurt, and insulted by those complaints which the less fortunate and apparently more reasonable shoemaker is every day or hour under the compulsion of submitting to the consumer, about the leather breaking, tearing, or cracking, or of its pressing on the foot with the severe hardness of an uncomplying piece of wrought-iron.' After some remarks indicative of his confidence in the ability of British manufacturers to excel both in ordinary and in choice leathers, as they confessingly do in some other kinds, he further observes that 'were the same substance of leather to be wrought generally into boots and shoes by the British manufacturer as is wrought in France, by the French manufacturer, the less would be the objection would be still more glaring; and hence we are often compelled into clausines, to make the coarse and unwhitely that we may produce the serviceable, and so save the pocket of the consumer, and make the upper part of his foot more pleasurable wear.' 'Our roads too,' he proceeds, 'with which we line our boots and shoes, can bear no comparison with the roads of our neighbours; they are in many cases so hard and stiff with the constant tread of other clyder that they bear upon the matter of the skin, and are so scorched on the skin with various chalks and pigments to produce the requisite surface, that the nail or needle in working is continually being thrust into
many loose fibres, thus rendering the work not anything like so agreeable or so perfect as it ought to be. Add to which the quick manner in which such lining dries and roughens in the air, a shop, and in the hands of the customer.

In purchasing dressed leather, Mr. Devlin recommends the shoemaker to take care that it be not of too large growth for its substance, and that, if waxed calf, it have ‘a free easy grain.’ Wax is useful, but, when it is inwardly a little, discovering a series of diminutive ridges or curls,—a pretty correct token that such leather has not been taken down too deeply.’ ‘It should always,’ he says, ‘be lofty and soft to the feel, not rank with grease, but yielding and smooth from the manner it has been wrought.’ Skins freshly curried should not be bought for immediate use, ‘all calf or other oil-dressed leather being the better to be laid by, skin over skin, for a month or two before they are cut; leather in this condition, as the phrase is, fastening, and thereby attaining a more durable character.’ ‘The qualities of sole leather, which is generally better in England than in any other country, are, according to the same writer, ‘defined by its closeness, weight, and, when cut, by the uniform healthiness of hue it offers to the sight; badly tanned hides being generally streaky, black, brown, grey, and green.’

Hobert describes two compositions which have been patented as substitutes for leather. Of these, Gunby’s, patented in 1824, consists of an elastic coating or varnish of glue-size, bored into seeds, lampblack, white lead, and pippesary, varied according to the soil in which the elastic hemp is acquired, spattered upon cotton, linen, or woollen cloth, or upon felt; while Hancock’s consists of a felted fabric of flax, cotton, or other material, covered with several coats of liquid caoutchouc. Each of these, however, is chiefly intended for the manufacture of patent ties, but is suitable also for covering coach-tops, and for some other purposes.

LEBANO-STAPHYLARIA [Leverworts, P. S. L.]
LEFEBVRE, ANTOINE COTTRIGHT, P. C. S.]
LEFEBVRE, FRANCOIS JOSEPH, Duke of Dantzig, and Marshal of France, was born of humble parents, at Raffach, in Upper Alsace, on the 25th October, 1755. He was preparing for the ecclesiastical profession, but having lost his father, he enlisted, when eighteen years of age, as a private soldier in the regiment of French guards. He had attained the rank of serjeant-major when, on the breaking out of the French revolution, that regiment was dissolved. The changes which then took place in the government of France removed those obstacles which prevented the promotion of meritorious soldiers who were deprived of the advantage of a college education. The merit of Mr. Lefebvre’s abilities was interposed in their behalf, and, at the peril of his life, rescued them from an infuriated populace. His subsequent rise in the army was without precedent rapid, even at that period: on the 3rd of September, 1793, he was appointed adjutant-general; on the 2nd of December, in the same year, he was a general of brigade; and on the 10th of January, 1794, he rose to the rank of a general of division. While serving with the army of the Moselle, he distinguished himself at the battle of Lammersbach, and in the battle of Giebzig. During the whole of the campaign in Germany and the Netherlands, under Fiegerow, Moreau, Hoche, and Jourdan, he made himself conspicuous for his skill and courage. In 1796, when the French army under General Kléber had passed the Rhine [Kléber, P. C. S.], the Austrians, finding themselves compelled to retire from Uckerath, had entrenched themselves, twenty thousand strong, on the heights which surround the small town of Altenkirchen. Their formidable position was attacked on the 4th of June by Kléber, who formed his army into two divisions, the first of which, the advanced-guard, he placed on its left, and the second, of which he placed on its right, fell on that division, which boldly charged the enemy at the point of the bayonet, and, in spite of a most vigorous resistance, compelled them to retire in disorder, leaving behind them forty thousand best soldiers, and about twelve thousand prisoners. On the 25th of March, 1799, was fought the memorable battle of Stockach, in which Lefebvre acquired fresh renown; with only eight thousand men he resisted, for many hours the attack of thirty thousand Austrians. For these eminent services however Lefebvre appears to have been but poorly rewarded, and there is extant a letter from him to the Directory at Paris, in which are contained the following passages, sufficiently characteristic of his manner and manner of thought:—‘The definite conclusion of peace,’ he says in it, ‘will enable the country to dispense with my services. I petition you therefore to assign me a pension which may maintain me in comfort. I ask not for carriage or horses, but only for bread. My services must be well known to you, and I shall not enumerate my victories; as for defeat, I have none to reckon.’

At the time when Bonaparte was placing himself at the head of affairs, the Directory, who supposed Lefebvre devoted to their cause, appointed him to the command of the guards of the Legislative Assembly; but, on the morning of the 18th Brumaire (November 9th), 1799, at Bonaparte’s private residence, and cordially co-operated in their proceedings. He was also instrumental in extricating Lucien Bonaparte from his dangerous position in the stormy days of Brumaire. On the 14th of May, 1804, he took his leave of Bonaparte’s private residence, and cordially co-operated in their proceedings.

In the year 1804 he was raised to the dignity of a Marshal of the Empire. He accompanied Napoleon the following year in the Austrian campaign, and in 1806 took an active part at the battle of Jena, where, though at that time upwards of fifty years of age, he fought on foot at the head of the guards.

In 1806 he was sent with an army of sixteen thousand men to invest Danzig, which was garrisoned by twenty thousand troops, besides a numerous militia, and the investment was completed on the 14th of March. A body of twelve thousand Russians were advancing to the relief of the besieged, and Lefebvre was compelled to divide his force, and to throw a portion of them to oppose the Russians. On the 15th of May a severe action took place between them and the French, when the latter were defeated by the troops of General Czartoryski and General Oudinot, who had been sent by the Emperor to assist them, successfully repelled nine Russian regiments, and a part of the Prussian garrison by whom they had been joined. On the 21st, after a short and severe struggle for a great valley, the Prussian commander General Kalckreuth offered to accept terms of capitulation; the long resistance which this fortress, among the strongest in Europe, was still able to make, rendered these terms as favourable as could
be expected. The garrison were allowed to retire with the honours of war, and to take with them their munition and baggage, on the condition of giving their parole not to serve during the space of one year against the French or their allies. The French kept the peace of the two generals, who lent him so powerful an assistance, to join him in the honour of signing the capitulation, but with a similar generosity, they declined to share with him a triumph which he had reached with their help. But always after these events, Napoleon, who was desirous of reviving the high nobility in France, and to give additional lustre and more munificent rewards to the twenty-four grand dignitaries who had saved him, the day before the battle of Leipzig. This marshal being highly esteemed by the army, and his eminent services during the wars of the Revolution having acquired for him the gratitude and respect of every Frenchman, he was selected by him as the first person on whom to confer the ducal dignity. The siege of Danzig indeed was one of the most brilliant triumphs of the Prussian campaign. Eight hundred pieces of cannon and immense magazines fell into the hands of the conquerors, and the capture of this important fortress not only secured the left flank and rear of Napoleon's army, but left to Prussia only the stronghold of Pillau along the whole coast of the Baltic. [D'Anzi, P. C.] In the year 1808 Lefebvre joined the Persian expedition, and was appointed to the command of the fifth corps of the French army. On leaving, the Emperor had given him directions to keep the Spaniards in check till his arrival; but an enemy's army was marching toward Spain when the enemy were seriously harassing the flanks of his army, he gave him battle, and on the 1st of November triumphantly entered the town of Bilbao. His conduct on this occasion enabled him to serve Napoleon, not only by interfering with his plans of operations, but afterwards present at the battle of Tudela, where he had the command of the cavalry. [Larue, P. C. S.]

In the German campaign of 1809 he rendered himself conspicuous as a brave soldier and an excellent tactician, at the battles of Eckmühl and Wagram, and in the dangerous warfare among the passage of the Danube and the Ticino. He was also with Napoleon in the disastrous expedition to Russia, and had the command of the old guard, which was however seldom called into action; but during the retreat he showed considerable military skill, and, for the most part, accompanied his corps on foot, sharing every suffering and exposing himself to every danger in common with the private soldiers. During the campaigns of 1813 and 1814 he appears faithfully to have adhered to the declining fortunes of his master, and after the battle of Leipzig, when the remnants of the French army were called to fight for the defence of their native country, by none of his lieutenants was Napoleon more adored for his valor or merceability than by Lefebvre, who acted in April, 1814, at Arcis-sur-Aube (March 20), and at Mont-Mirail (April 14), he displayed the same gallantry as in the more renowned but not more glorious fields of war. For his services in the campaign of 1814 Napoleon greatly influence the abdication of Napoleon, and at the first restoration of Louis XVIII. he was created Chevalier of St. Louis and peer of France. But on the return of his former chief from Elba, we find him again adhering to his fortunes, and accepting a seat in his Chamber of Peers, where however he held himself aloof from all discussions. (Journal des Debats of the 10th April, 1814.) At the second restoration of the Bourbons, he was excluded from the Chamber of Peers, to which he was recalled in 1819, having been a few years previously reinstated in his rank of marshal. He died at Paris on the 14th of September, 1820.

The military career of this distinguished general is perhaps more to be admired than his public character; it being difficult to reconcile his conduct, during the latter years of his life, with genuine patriotism. His manners evidenced the pleasure of the king; yet to the last he had not lost any of the memory of his husband in the cemetery of Père-la-Chaise. The character of this excellent woman, who was of most humble origin, may be best judged by a trait which Lis Casse praised in him. She was the second wife of a poor tailor, who had three years to serve as a grand officer; and, finally, to obtain the highest grade, which is that of grand cross, he must have served five years as a grand officer.

When a prominent talent in the arts of war appears as the king determines the number of decorations of each grade, and a distribution is made by the chancellor of the order in the following proportion, 40 to 40:—
On all public occasions certain military honours are due to personages decorated with this order, and, at all times, a soldier on different accounts is on more than one decoration. The following salaries are attached to the different grades: chevalier, 250 franes; officer, 1000; commander, 2000; grand officer and grand cross, 5000.

In the formation of this order, as first designed by Napoleon, though of a strictly military nature, the honour was not restricted to military men alone, but was intended to be the reward of civil, scientific, and literary services. He wished, moreover, that the name which he gave it should imply its object, which was to form a body of the most distinguished citizens, specially bound together by the ties of honour and devotion to their country. The legion, which was to be composed of men who were not connected by a supreme council, composed of seven members, the three consuls, and four grand officers—the first of whom was to be chosen by the senate, the second by the legislative body, the third by the military senate, and the fourth by the council of state. He likewise enacted that all military men, who had previously received honourable distinctions for their services by the republican government, should be, of right, members of the order.

The proposition of the first consul, when presented to the legislative body and to the tribunate, met with a violent though unexpected opposition. The representatives of the French nation could see in it nothing but a powerful weapon of military despotism, to be sooner or later wielded by one whose projects of absolute rule were beginning to be discovered. His brother Lecien, moreover, to whom the motion had been entrusted, by his impudent zeal in urging its adoption, raised in the minds of many the idea that he was enforcing the interests of his family rather than those of the nation. Even in the council of state, which, by the nature of its constitution, was especially under the influence of Napoleon, it was deemed by some to be a most dangerous experiment, calculated to reconcile aristocratical feelings, and gradually to introduce the ancient régime; while others, answering the more general observation, that distinctions, when distributed without regard to the constitution should be restricted to military men. Among the representatives of the people, the general expectation of the institution itself was still more strongly contrasted with the Roman senate, where, they felt, the powers of the tabiens, 'the pillars of an hereditary throne; they were unknown to the Romans when they conquered the world.' The first consul's reply to these different objections was a remarkable proof of his prescience and correctness. 'Such ideas,' he remarked, 'might be well adapted to the feudal ages, when the knights were accustomed to combat together, man to man, and the bulk of the nation was reduced to a state of slavery. But when the military system changed, it was then not prowess in war, but science and skill, which decided the fate of nations. In all civilized states military force must of necessity yield precedence to civil qualities. Bayonets must lower before the priest who speaks in the name of heaven, or the man of science who has obtained an influence by the ascendancy of his knowledge. Think not that it is a general that I govern France; but because the entire nation believes me possessed of that ability in the direction of civil affairs so necessary to a ruler; without it I could not, for an instant, keep my ground.'—France, he continued, 'contains thirty millions of men, united together by the ties of intelli-
gence, property, and commerce; what are a quarter of four hundred thousand soldiers in comparison to such a mass? and, moreover, not only does a commander preserve his influence and ascendancy over the soldiers of his army chiefly in virtue of his qualities as a man, but, when his command ceases, he returns to the rank and position of a private individual. The natural tendency of military men is to carry every thing by force; the enlightened and educated civilian, on the other hand, elevates his views to the perception of the general good, and follows an opposite course of conduct. I have no hesitation in assuring that, if a preference is to be awarded to the one rather than to the other, it belongs to the civilian. If you divide society into two orders, soldiers and citizens, you create disunion into what should be but one body.' Influenced by these arguments, a majority of the council agreed to the proposed honours should not be indiscriminately to civil and military men of distinction. At length, after many an angry discussion, the project was passed into a law on the 29th Floréal (May 19th, 1802), in the national assemblies; in each of them, however, but by a small majority.

The Legion of Honour, though it undoubtedly seemed a forerunner to that new nobility which Napoleon, in after years, created in the form of the Légion d'Honneur, was the highest degree important to his interests, and popular among the nation. On the 24th of July, 1804, Napoleon distributed to the principal civil and military dignitaries of France the higher order of decorations. The splendid church of the Hotel des Invalides was the place appropriately selected for the distribution. He had not as yet given the decorations of this order to foreign courts; as a prelude to doing so, he bestowed it upon the venerable Cardinal Caprara, who, in his capacity of legate, represented Pope Pius VII. at Paris, and, to enhance the value of the honour, on that occasion, detached from his own neck the ribbon of the Order of the Garter, as representative of a church with which France, through his instrumentalities, had been happily reconciled (Thiers, *Hist. du Consulat, &c., b. xii.* [Bonaparte, P. C.])

But a more interesting spectacle was that of the assemblage of the vast army which Napoleon had assembled at Boulogne, preparatory to his intended invasion of England. On the 14th of August, 1804, the festival of his tutelar saint, nearly thirty thousand men were drawn up on the slopes of the large natural amphitheatre, on the western side of the hill, on which is situated the so-called tower of Caesar. An elevated throne was raised in the centre of this theatre, and the soldiers were ranged in four long rows of a circle emerging from this throne as their centre; beyond them was congregated a countless number of spectators. At mid-day the emperor ascended the throne, amid the din of military salutes and the acclamations of the crowd; near him was placed the famed buckler of Francis the First, while the decorations of the order about to be distributed were contained in the helmet of the illustrious Chevalier Bayard. He was surrounded by his brothers, by the chief functionaries of the empire, by the marshals and generals of his army. Amidst this proud army were to be seen the ancient standards of the republic, the witnesses of the victories of Rivoli, Acreola, and Marengo. In presence of the great, the generalissimo was drawn up in such a manner as to give adherence to the laws of this order and of his country first himself, and afterwards administered it to those around him; then, raising his voice, and addressing the veterans of his army, he continued, 'Citizen officers, you, on the slopes of the hill, are the custodians of the sacred law of your country, the hazard of your lives, the honour of the French name, your country, and your emperor.' This animating appeal was responded to by the deafening shouts of the mighty militia of the Fatherland. With these words was brought to an end a rapidly moving scene, and this imposing ceremony was concluded by a general review of the whole army, whose ranks defined before the imperial throne. Napoleon estimated at twenty-five thousand the decorations he had distributed during the ten years of his reign. This remarkable institution has outlined the fortune of its founder. Its benefits were appreciated by the Bourbon, who soon discovered that it was the most powerful means they could employ of increasing their popularity, and giving stability to their precarious position. It has been wisely adopted, and its utility has been increased, under the pacific reign of the house of Orleans. By its means the present king of the French has been enabled, at a comparatively small expense to the state, to consolidate the esteem and to reward the merit of the most deserving citizens. It has been placed on the breast of an Arago, a Guizot, and a Thiers, with equal honor, as such an appellation, as it has been of those of a Ney, a Massena, and a Lannes. It is the erudite of the French nation that, while no other people are perhaps so much under the influence of military renown, it should become the habit of the French nation to distinguish where men of science and literature are more generally esteemed and rewarded.

But the benefits which have accrued to the French from this institution may be best described in the eloquent
words of one of their living historians, in his history of the county. His Epitaph says, 'In memory of this order, he says, 'dates scarcely more than forty years existence, and it is now consecrated in the memory of the people, as if it had passed through the lapse of many ages; so much has it become a part of the local life, that it is full of life and spirit, and every kind of merit; so much has it been sought after by the great and principal personages of Europe, those even who pride themselves the most on the honours of their ancestry. Time has shown that when he came to determine the distinctions, he has declared in favour of its worth and utility. Leaving aside the abuse which has occasionally occurred in the distribution of its distinctions, under the various governments which have followed each other, it would be sure to be noticed, the rewards bestowed by man upon his fellow men, let us gratefully recognize what there was novel in plan, profound in design, and beautiful in execution in an institution whose object it was to place on the breast of the common soldier, or on that of the unassuming man of science, the same decorations which was destined to confer distinction on the commander-in-chief of armies, on princes, and on kings; let us recognize in the creation of these honourable rewards, the most brilliant triumph of true equality, that equality which raises instead of abusing the minds of men: let us recognize, in short, that if to the great in civil or military life it might become a new gratification of vanity, it was to the common soldier, returned to his domestic hearth, at once the pledge of honourable ease and a visible proof of his former prowess.'

The following statement of the rewards which have been conferred since 1796, shows the number of the Order of the Bath, who have taken place in the members of this order, and also how liberally its honours have been distributed by the present king of the French. We are indebted for the latter part of these details to the lists of the Union of 974, and to the里面 of 975; it being a curious detail in the history of the Order, that this list of the different orders of the Order of the Bath, the entire number of members of all the different divisions of this order were 97,747. We have stated above the number which Napoleon estimated that he had distributed during his reign.

The following detail will show the increase during the reign of Louis Philippe.

Thus it appears that there has been an increase during fourteen years of 8,418 members; the diminution in the highest decorations has probably arisen from the deaths of many of the old nobility who had been numbered in all the years of the order, and the number of the order at the year 1844, 29,843 received no pension, and 19,851 drew the salaries attached to the order. The revenue during the year was 7,000,000 francs, about £280,606, and the expenditure 2,807,728 francs, about £277,500. Our information respecting that year is derived from the French newspaper 'Le Courier de l'Europe' published in London.

A full account of this order and of its most distinguished members may be found in a work entitled 'Fautes de la Legion d'Honneur,' 4 vols. Paris, 1842 and 1844.

LEGITIMATION. [Bastard, P. C.] -

LEGUMINOSAE, a genus of crucial fruits, from the Islands of the West Indies, the East India, and the Moluccas. The most celebrated is Leech, of Holkham, Thomas William COKE, Earl of. Thomas Coke, Esq., of Holkham, in Norfolk, great-great-grandson of Sir Edward Coke, great-grandson of Sir Thomas Coke, baronet, who was Lord Chief Justice of England, 1727, was appointed by his father, Sir William Coke, of Minster Lovell, in Oxfordshire; and in 1744 Viscount Coke of Holkham, and Earl of Leicester. On his death without offspring, in 1750, the title became extinct, and the estates went to his nephew Weiman Roberts. Esq. (the son of his sister Anne and her husband, Colonel Philip Roberts, who thereupon assumed the surname and arms of Coke. The subject of the present notice was his son, by his wife Elizabeth, daughter of George Anson, afterwards Denton, Esq., and was born on the 4th of May, 1752.

His father, who had been returned to parliament as member for the county of Norfolk at the general election in 1774, and who was the son of his late father, Member of Parliament for the town of Derby, died in 1776; upon which his son succeeded to the representation of the county. In a speech which he made at a dinner given to him in 1833, he stated that, having previously held the position of one of the most influential members in the House of Commons, he was bound to the people of Norfolk, and that he would support the government, and supply the country with the best men. He was elected for the county of Norfolk in 1834, and was returned for the county of Suffolk, and was re-elected for the county of Norfolk at the general election in 1835; but after the dissolution in March, 1842, he was one of the numerous supporters of the late unpopular Coalition Ministry, who were thrown out, and who received the name of Fox's Martyrs. He recovered his seat however in 1790; and he was also reelected without a contest in 1796 and in 1802. At the next general election, in 1806, he was returned by a majority of 4110 to 3772 over Mr. Windham, but was unseated by a Committee of the House; upon which he was re-elected for the county of Suffolk, and his younger brother, Mr. Edward Coke, who had vacated his seat for that borough, was also re-elected for Norfolk. At the general election, in 1807, Mr. Coke became again member for that county, which he continued to represent down to his retirement from the House of Commons in 1825.

Mr. Coke, though a born steady partisan, was not a frequent speaker in parliament. The two occasions on which he appeared most conspicuously were, on the 24th of March, 1783, when in a short speech he moved an address to his Majesty, requesting that his Majesty would be pleased to lay before the House of Commons, and an administration entitled to the confidence of the people, which, being assented to, was followed by the resignation of Lord Shelburne and the formation of the Coalition Ministry of Mr. Fox and Lord North; and on the 20th of March, 1784, when he carried two motions against the existing ministry of Mr. Pitt, which however had no effect. He also on subsequent years came forward on some occasions when measures affecting agriculture occupied the attention of the House. In all matters of general policy he voted with Mr. Fox, and after his death with Lord Grey and what was commonly called the Whig party.

His influence in the country arose from his large estates and the lead he took in agricultural improvement, together with his popular qualities as a landlord and a country gentleman. He is said to have been the first to introduce the new system of culture, which he practised in Holkham, in the period of between sixty and seventy years during which he had been in possession, from little more than 2000l. to above 20,000l. From the death of Francis, duke of York and Albany, he was confirmed in the possession of the estate, which he repossessed in 1797.

His plantations were so extensive that the average value of the annual full of timber on his property is stated to have amounted to his death at 2700l., or considerably more than the entire rental of the estate when it came into his hands.

The annual sheep-shearing at Holkham, at which some hundreds of guests were entertained for several days, was probably the greatest agricultural festival in the world.

According to Mr. Coke's own account in the after-dinner speech of 1833 already quoted, he was twice offered a peerage in the very first session that he sat in parliament. More than sixty years after, namely, on the 21st of July, 1827, he was at the Upper House of State, as Earl of Leicester, of Holkham. It is understood that which had prevented his being sooner made a peer was that he would accept of nothing except this earldom of Leicester, which had been announced by his maternal uncle, Mr. Coke of Hatfield, in 1822. Of the great estates which he had inherited, but which had in the mean time been bestowed, in 1784, upon Lord Ferrers, afterwards Marquis Townshend, to whose heirs it of course descends. It was the project of his eldest son, the present Earl of Leicester, to have the title of the same name, with the slight and not very intelligible variation, 'Leicester of Holkham,' bestowed upon a second person. It made no difference to him that the other Earl of Leicester had subsequently acquired a title as well as the name, for the title was still contemporaneously as much Earl of Leicester as Marquis Townshend. The proceeding was precisely the same
L E M

nature as if Mr. Coke had been made Duke of Wellington, of Holkham.

The Earl of Leicester died at Longford Hall, Derbyshire, on the 30th of June, 1832, at the venerable age of ninety. He was twice married: first, in 1775, to Jane, daughter of John Sackville, 1st Earl of Dorset, who died in 1800, and by whom he had three daughters, and many granddaughters and great-grandchildren; secondly, on the 26th of February, 1822, to the Lady Anne Amelia Keppel, third daughter of the Earl of Albemarle, who was then eighty-nine years of age, and who brought him five sons and a daughter. The eldest son, born on Christmas-day, 1822, is now Earl of Leicester.

(Memoir in the Gentleman's Magazine, Sept., 1842. See also the number for December, 1842, a short notice of his will, in which he is said to state in that document that he had 'lately expended the sum of 500,000l. in the improvement of his estate."

LEI'GON, a genus of fossil reptiles. (Owen.) One species found in the chalk of Norfolk.

LEIPA (generally called Böhme-leipa), is a town in the circle of Leitomitz, in the kingdom of Bohemia, and in the lordship of Neuschoss, belonging to Prince Kauinitz. It is situated on the river Polza, and has about 6000 inhabitants, who have flourishing manufactories of woolen-cloth, cottons, calicoes, and damasks, and very beautiful earthworks and glass-works. There is a gymnasium and a high school in the town. (Hirschelmann, Handbuch; Stein, Lexicon; Cannabich, Lehrbuch.)

LEIPF., a genus of plants belonging to the natural order Aroidae, and the suborder Lenmeg. It has a 3-flowered membraneous urceolate spathé; the male flowers consist of two stamens; the fruit is recticular and indeliscent. The flowers are sessile, and the rachis of three or four leaves. The flowers appear just below the margin of the spathé. Several species have been described. 'They are all inhabitants of stagnant waters, and are known familiarly by the name of 'duck-weeds.'

(Lubbock, Memoirs of British Botany.)

LEMOINE, FRANCOIS, a celebrated French painter of the eighteenth century, was born at Paris in 1688. He was the pupil of Louis Galleco, early distinguished himself, and, being named a member of the French Academy. Painting: his presentation-piece was an excellent picture of Hercules killing Cacus. He obtained a great reputation by his painting, in oil, of the Transfiguration of Christ on the ceiling of the church of the Jesuits, Rue du Bac. In 1724 Lemoine visited Italy, where he remained for a year; the artist whose works chiefly attracted his attention were Pietro da Cortona, Lenfreanc, and Bernini. After his return to France he was made professor of painting in the Academie, and in a very few years his reputation surpassed that of all his French contemporaries: Louis XV. appointed him in 1736 his principal painter, with a salary of 4000 francs, in the place of Chardin, who was at this time in Italy. The first of Lemoine's great works was the cupola of the chapel of the Virgin in St. Sulpice, in fresco, which he commenced in 1729, a work of three years labour. His master-piece however is the cupola of the church of St. Sulpice, painted on canvas, painted on the ceiling of the Salon d'Hercole at Versailles, commenced in 1732 and finished in 1736. It is a grand composition, containing one hundred and forty-two figures, and it is the most extensive and most magnificent monument of painting in France, though in a florid and superficial style, and, like the works of his model, Pietro da Cortona, belongs to the class of works called pituré di maschino by the Italians. The composition is arranged in nine groups, in vigorous and expressive arrangement, colour, and light, and especially in aerial perspective; but it is a purely decorative work, and is effective only from a distance. The parts have little individual merit, and the drawing wants correctness, expression, and descriptive character. Lemoine used on the ground of this picture, the blue vault of heaven, ultramarine to the value of 10,000 francs; it is this which gives the work its fifity-four.

After the completion of this great work he was without a rival in France, but he never enjoyed his success. He was naturally of a melancholy temperament, a weakness which the habit of his profession and the constant application of his mind to the task of a painter, arising from an insatiable ambition, combined with vexation on account of the decoration of his less successful contemporaries, aggravated to that degree that it amounted to a chronic aberration. He had been destroyed in one of these nervous fits, June 4, 1737, ten months after the termination of his great work at Versailles, and in the fifth year of his age.

Lemoine painted also many easel-pictures, both of large and of very small dimensions, and the latter have realized high prices at auctions: a Flight into Egypt is considered his best easel-piece. There is not a single picture by him in the Louvre at Paris. Many of his works have been engraved by Jean Baptiste Monnoyer, who died in 1721, and who had the honor of being one of the most famous engravers of his time.

H. S. Thomassin, Silvestre, Lermans, Et. Fessard, &c., loucher, Natoire, and Nonnotte, distinguished painters, were the pupils of Lemoine.

(D'argenville, Histoire de la Vie des plus illustres Peintres; Waterlet, Le Dockeur, Dictionnaire des Arts, &c.; Gault of Saint-Germain, Trois Siecles de la Peinture en France.)

LENCIUSCUS. The reference from Bleak, P. C., to Lencius was a misprint for Lenfant.

LENFANT, JACQUES, was born at Beuze in Bceu, a district of the ancient province of Orléanais in France, on the 13th of April, 1681, and was the son of Paul Lenfant, the Protestant minister of Châtillon-sur-Scine. Being destined to the same profession as his father, he was sent to prosecute his studies at Saumur; during his residence at that university he lived with the learned Jessuel, the professor of Hebrew, with whom he formed a friendship, which continued during their lives. He afterwards completed his theological education at Geneva and Heidelberg, in which latter town he was admitted into the ministry of the Protestant church. During his stay at Geneva he obtained the appointment of minister of the French church at Heidelberg, and chaplain to the Dowager Electress Palatine. The invasion of the Franks by the French troops, under Marshal Turenne, in 1690, compelled him to leave Saumur, and he was appointed minister of the French church at Heidelberg in 1688, and was settled at Berlin. The fear of meeting his countrymen arose from having rendered himself conspicuous to the Jesuits by two letters which he had written against them, and which he wished condemned. He was entitled 'A Preservative against a Re-union with the Church of Rome.' Though the Protestant French church of that city had already a sufficient number of pastors attached to it, the reigning minister of Brandenburg, Prince Leopold, the King of Prussia, who knew Lenfant by reputation, appointed him to that church, where for upwards of thirty-nine years he performed duty. In the year 1705 he married Mademoiselle Montfeuil, the sister of Madame Poitou. In 1707 he visited England, and it is recorded that he was admitted to preach before Queen Anne, though we do not understand how he could have been permitted to do so without having received episcopal ordination; it is further stated that the Queen wished him to enter the Church of England, and offered him, in case he resolved to do so, to appoint him her chaplain. In 1710 he obtained the situation of chaplain to the King of Prussia, and councillor of the high constabulary. He was also a corresponding member of the Society for the Propagation of the Gospel in Foreign Parts, which had a few years before been established in London. Lenfant was a man of great learning and much erudition, and enjoyed the perfect health, on the 29th of July, 1728, and he died on the 7th of August following.

His disposition is represented to have been amiable, and his manner unassuming, and he was always in the habit of speaking blunt and little. Though a most volun- tuous writer, he was fond of society, and opened himself without reserve to the confidence of his friends. He is said to have had few personal enemies, which may be readily be- lieved, for his character is universally described as remarkable for its disinterested charity, and for the exercise of the peacible virtues of a Christian. As a preacher, his manner was pleasing and persuasive: the manner of his discourse was chiefly of a practical nature, and his eloquence was rather calm than energetic. His varied talents and the depth of his learning may best be judged of by the study of the numerous and valuable works which he has left, many of which are of indispensable utility to the theological student. The style of his writing is elegant, though never florid; it has lost for the most part of Joubert's [Jouber] beauty and eloquence than that of Saurin [Sauve, P. C.]. The eloquence was more pure, and the diction more chaste. In one respect especially he is far superior to any of the French Protestant writers, and that is in the bold and open manner with which he set his foot on the bosom of the Church Germanique,' which was commenced in 1720, but it is well known he took a prominent part in its execution, and he is the acknowledged author of the preface.
LEO 197 LEP

Leonard's first work, which appeared in 1683, was a review of one of Bruyas, who, though a celebrated French dramatist, has written several theological works in defence of the Roman Catholic faith. In 1688 he published a translation of a selection from the letters of St. Cyril, in 1690, a defence of the Hildebrand cælianch, which is generally annexed to his 'Preservative,' &c., a work we have before alluded to; and in 1691, a Latin translation of the celebrated work of the Pope Melchisedech on 'Research after Truth.' His life, like that of his predecessors, is generally divided into two parts, to which the arguments in it are drawn from the Latin dissertation on that subject of Spanheim. It is said, however, that, in after life, Leonard Melchisedech acknowledged the absurdity of this section. [Joan, Pops, P. C.] In 1708 he published in Paris, on the Greek edition of the 'New Testament,' by Mill, which are in the 'Bibliothèque Choisiot' of Le克莱, vol. xvi. The following works afterwards appeared in succession: 1. Réflexions et Remarques sur la Fortune du Père Martyr, avec un Juif; 2. Mémoire Historique touchant la Communion sur les deux Espèces; 3. Critique des Remarques du Père Vawa; sur les Réflexions de Basle touchant la Politique; 4. Réponse de Mons. Lenfant & Mons. Daritis au sujet du Socinianisme. The above short works are to be found in the 'Nouvelle de la République des Lettres,' a review in which Leonard often contributed frequent articles. In 1714 was published his learned and interesting 'History of the Council of Constance,' 2 vols., Amsterdam. Two years after he wrote an apology for this work, which had been severe criticized. In 1720, in conjunction with Boussoube, he published a translation of the New Testament, with explanatory notes, and a long and most learned introduction. It is by this work, perhaps, that he is best known. [Census, xvi.] We shall now briefly mention the most important of his productions: 1. Poggiana; or the Life, Character, and Maxims of the celebrated Florentine writer Poggio, Amsterdam, 1720; 2. Recherches sur les Arts; 3. Histori de la Syrie, d'Egypte, et de la Communion, during the interval between it and the Council of Constance; a learned and most accurate work, written with sufficient impartiality, 1724; 4. A Volume containing sixteen Sermons, on different Texts of Scripture, 1728; 5. A General Preface to the Old and New Testaments, which is appended to the French Bible in octavo, published at Hanover and Leipzig in 1729; 6. A small volume of Remarks on Gisbert's Treaties on Falsit Eloquence. The last work of Lenfant is one which has greatly added to his already high reputation. 'The History of the Wars of the Huns, and of the Council of Basle,' 1728; but the labour which the composition of it occupied the author for many years collecting materials for this valuable history, and had access, through the influence of the King of Prussia, to the archives of the corporation of Basle. The principal defects of the work are best known to have been taken from a memoir annexed to the above work.

LENTIBULARIE. [LEN'TIBULAR.'E. P. C.] LENTIBULARIE. (from Latin, 'a lion,' and 'a tail,' the tail.) A genus of plants belonging to the natural order Laliaceae. The anthers approximate in pairs, with parallel colls and naked valves. The upper lip of the corolla is nearly flat, the lower one trident, with the middle lobe oblanceolate. The calyx is tubular and 5-toothed; the nectary truncate.

L. cardua., Motherwort, is a bitter herb, with a pungent unpleasant smell. The stems rise from 2 to 3 feet in height; these are quadrilobed, and the leaflets are serrate. The leaves are long-stalked, somewhat downy, and of a dark green colour. The lower leaves are the broadest, and deeply jagged, the upper ones 3-lobed, and those about the summit lanceolate and acuminate. The flower-cluster, or the spikes, are usually hairy; the calyx rigid and pungent. It is found in hedges and waste places in Great Britain, all over Europe, and the middle of Asia. The reputed tonic powers of this herb are not very decided; it is more especially used for coughs, or heartburn, are now disregarded: from being used however in the last complaint it derives its name. It has been extolled by the Russians as an antidote to canine madness, and bees are said to have eaten the fruit. [Thunb., p. 390; or, p. 383.]

L. marrubastrum has elongated pubescent branches, oblong ovate deeply-toothed leaves, the calyx nearly glabrous, and the corolla small, white or pale-red, and shorter than the calyx; the petals, which are subulate, spiny, and diverging. It is found in waste places throughout Europe and Asiatic Russia. There are eight species of Lepidium described by botanists as growing chiefly in Europe and the North of Asia. None of them are very ornamental, and being biennial plants, the seeds only require to be sown in the open ground, or winged at the back. There is but one seed in each cell; the filaments are simple. The species consist of herbs or small shrubby herbs with small white flowers. This genus is divided into seven sections, the first of which, Cardaria, is so called from the heart-shaped form of the silicles. To this section belong:

L. Draba. It has oblong leaves, entire or toothed, the lower ones narrowed into a footstalk, the stem leaves sagittate and amplexicaule, the style as long as the disciple. It is native in the south of Europe from Spain to Tauria, and from Greece to Paris. It was introduced into Great Britain probably by foreign seed, and is now found in the hedges of Kent.

L. sativum, common Garden Cress, belongs to the section Cardamomum of this genus. It has orbicular pods, variously cut and winged leaves, the pods being flat, and occasionally attached to the island of Cyprus in corn-fields. There are three varieties of the species: the broad-leaved cress, which is cultivated chiefly for rearing young turkeys; the curled variety, which is sometimes found, has the leaves considered preferable as a garnish; and the common plain-leaved cress, which forms one of our earliest spring salads, and has a peculiarly warm and grateful relish. All the varieties are raised from seed, of which one foot is sufficient for a bed or four feet square. Cress should be raised four or five times a month so as to have the crops delicately young in succession. When raised in the open garden it should be sown early in March, and if the weather be cold it should be covered with a cloche or a frame frame during the night. Cress is often raised on porous earthenware vessels of a conical form, having small gutters on the sides for retaining the seeds. These are called pyramids: they are somewhat ornamental in winter, and afford repeated gatherings. This species is the Lepidium of Dioscorides, 2. 203.

L. campestris has downy leaves, the upper ones toothed, the lower ones oblong and narrowed into a foot-stalk, the stem leaves lanceolate, sagittate, and amplexicaule. It is distinguished from the other species by the pouch being ovate, rough, and covered with minute scales, notched and rounded at the end, the style scarcely longer than the nutch. It grows on gravelly and dry fields of Great Britain.

L. sativum has ovate lanceolate leaves, serrated or entire; the pouch is oval and downy. It has numerous small flowers in compound leafy pedicled clusters. It is a native of Europe, and occasionally found also of Alger; is a prevalent plant about the sea. It has a very hot biting taste, and has been used in stead of horse-radish, occasionally as a salad; the poor people are in the habit of eating it as a condiment to their food, hence it has acquired the name of Poor Man's Pepper. An infusion of it sets as an emetic. Fras believes this to be the Epilobium of Dioscorides, 2. 147, although it is usually referred to the Brasioid ciretica. It is also the Lepidium of Pinny, 20. 17. 19. 2.

The green-house species will thrive well in any kind of light soil, and are readily propagated by cuttings planted under a hand glass; or by seeds. The hardy annual species, by dividing at the roots or by seeds, will grow in any kind of soil. The hardy annual kinds only require to be sown in the open ground. None of the species are worth cultivating as ornament.

LEPIDOPTERAE [LEP'IDOP'TER.'E. P. C.] LEPIDOPTERAE. (from Greek, 'a scale,' and 'to bear,' bears.) A genus of fossil gemod fishes, alpercant in the oolithic strata. [Agassiz.]

LEPIDOPTERAE. [TANTHOIDES, P. C. S.] LEPIDOPTERAE. (from Greek, 'a scale,' and 'to bear,' bears.) A genus of fossil gemod fishes, occurring in the carboniferous and oolithic strata. [Agassiz.]

LEPTENA, a subdivision of the great family of fossil
LEWIS, BRACHIOPODA, proposed by Dalman to include species which Mr. Sowerby named Producta. Its use is at present more restricted, and has become rather indefinite. Leptatina lata of the Silurian system may be regarded as a frequent type. They are intertidal, living in the sand and crevices of rocks, and are common in north-western Europe.

LEPTITIDAE, Two-winged Flies (Diptera), of the division Tanytarsinae in Latreille's arrangement. They are remarkable for the habits of their larvae, which excavate funnel-shaped chambers in the sand, and secluding themselves at the bottom, lie in wait for their prey. When an insect falls into the pit the larva of the Leptesia suddenly seizes it, and clasping the body of the insect injects the juices, after which it flies away the carcase. Leptocaphehalus, a remarkable fish of the El tribe, discovered on the British coast in Pennant's time, and since observed in the Mediterranean. The Leptocaphehalus Merriani is a small, slender, and compressed animal, as thin as a piece of tape, and at first sight resembling a marine worm. The head is extremely small and short, the eyes large, the jaws furnished with numerous minute teeth; the pectoral fins and gill openings very small, and the anal and dorsal fins connected with the tail. The outline of the body resembles that of the Lancelet (Branchiostoma); but the organization of the Leptocaphehalus is that of a perfect fish. Mr. Yarrell describes the verterbrae as having no spiny processes, nor living among seaweed.

LECOT, PIERRE, a French architect of the sixteenth century, of whom, however, nothing is distinctly known, but he is generally supposed to have designed and commenced, together with Daumas, the Palais Royal, the present avenue for Henri IV. and Henry II.; the exact time is a matter of uncertainty. Lecot was born, according to some accounts, about 1515, and he lived to the age of sixty; other accounts give the date 1518 or 1517, as the years of his birth and death. He erected the southern and western sides of the quadrangle, but all that now remains by Lecot is the western side, facing the Tuileries, known as the Vieux Louvre; it contains the hall of Justice as the residence of the Dauphine, as well as the Dauphine's Saloon, and the large room in the south wing, known as the Salle des Caryatides, with the modern name of Salle des Caryatides.

Lecot's style and services to architecture have been the subjects of various speculations; but they are all extremely vague, and amount to very little. By some he is supposed to have been the first to abandon the old irregular Gothic, and to have introduced the Italian style into France; but this was done by Italian artists themselves, several of whom were employed by Francis I. long before Lecot could have attained anything like mastery in his art, or even maturity of years. Fontainebleau is an instance, in which Serlio, Primaticcio, and others, as well as Lecot, have been supposed to have had a share. Lecot is said also to have designed the "Fontaine des Innocents," attributed by some to Goujon, the sculptor of the nymphs of the Fontainebleau, who was Abbot of Cluny or Clugny, and a canon of the Cathedral of Notre Dame at Paris.

L'ESPINASSE, MADEMOISELLE, the name of a lady much celebrated in the Parisian literary circles soon after the middle of last century, was born in 1782. She is supposed to have been the illegitimate daughter of people of rank. She was employed to read and converse with Madame du Deffand in her blindness; but being ambitious, well-informed, and eloquent; she obtained, with much of what is said, she attracted the interest of the circle surrounding Madame du Deffand to an extent which greatly displeased that lady. She dismissed Madeleine, who had the boldness to plan, and more than once, even in the presence of what is said, she accomplished a high matrimonial alliance, and in one instance induced the relations of a noble Spaniard on whom she had made an impression to allow her to return to France, by promissory letters of credit, which she demanded attempts to establish the truth of this, and the date of its occurrence, as well as the probable situation of Madeleine, in her health. Morlot, the uncle-in-law of Marmontel, however, in his Memoires throws doubt on this story. She died in 1776, to the great grief of D'Alembert, whom she had long

198 mortified by not returning his affection. Three volumes of her love-letters, besides numerous and very ardent eloquence, were published in 1809.

LETTERS, CREDITS. [CREDIT, LETTERS OF P.C.C.] LETTERS, THREATENING. [THREATS, P.C.] LEUCISCUS, a genus of fishes of the family Cyprinidae, distinguished by having short and soft anal dorsal fins, and a mouth unfurnished with barbules. There are many species, and are common in brackish and fresh waters.

Those best known in Britain are the Roach (Leuciscus rutilus), the Dace (Leuciscus vulgaris), the Chub (Leuciscus cephalus), the Bream (Leucis ceus argyropterus), and the Minnow (Leuciscus phoxinus). More rare are the Grasse (Leuciscus tissotii) and Dace (Leuciscus idus) which is doubtfully recorded as a native of Scotland. Most of these fishes are sought after by anglers, either for the sport they afford or to be used as bait for pike. None of them are very excellent as food. The roach and chub have been known to attain a weight of five pounds.

The scales of several of these fishes have been used in the manufacture of artificial pearls. 'On the inner surface of perch, dace, bleak, whitebait, and other fishes,' writes Mr. Yarrell, 'is found a silvery pigment which gives the lurethere those fish appealing. The scales of the Roach, therefore matter thus afforded to imitate, artificially, the oriental pearl. When this practice was most in fashion, the manufactured ornaments bore the name of patent pearl, and the Roach was the most valuable of the species, and the most vogue. It present it seems confined to ornaments attached to combs, or small beads arranged with flowers for head-dresses. So great was the demand formerly at particular times, that the price of a quarter's weight of Roach scales was 12l., and in one month the trade was many times repeated. The Thamse fishermen gave themselves no trouble beyond taking off the scale sides, and throwing the fish into the river again; and it was the custom for bakers, regularly, to buy in scale sides, which were used to make funnel-shaped, soft rounds for the head-makers with the scales. The method of obtaining and using the colouring matter was, first carrying off the slime had dirt from the scales by a run of water, then soaking them for a time, the pigment was found at the bottom of the vessel. When thus produced, small glass tubes were dipped in, and the pigment injected into thin hollow glass beads of various forms and sizes. These were then spread on sieves and dried in a current of air. If greater weight and firmness were required, a further injection of wax was necessary. Of this pigment, that obtained from the scales of roach and dace was the least valuable; but it was found that from the scales of the roach there was the greater numbers; the whitefish afforded the most delicate and beautiful silver, and obtained the highest price, partly from the prohibitory regulations affecting the capture of this species fixed by the laws of transmarine and the royal decomposi-

(Les tory of British Fishes, vol. i.) LEVANT COMPANY. In 1681 Queen Elizabeth granted to a company the exclusive right of trading to Turkey. This was the origin of the Turkey or Levant Company. Its exclusive privileges of trade extended to the dominions of the Grand Seignor, whether in Europe, Asia, or Africa. Factories were established, and the company was at the cost of supporting an English ambassador at Constantinople, and consuls at Aleppo, Smyrna, and other places. Adam Smith speaks of the Turkey Company in his time, seventy or eighty years ago, as 'a strict and oppressive monopoly.' The Turkey Company provided no ve. LEWIS, MATTHEW GREGORY, a writer of novels, poems, and dramatic pieces, was born at London on the 9th of July, 1775. His father was deputy-secretary-at-war, and was John Combe, a former member of Parliament. Lewis studied at Christ Church, Oxford, and afterwards lived for some time in Germany. There he became acquainted with Goethe and his followers, and imbibed the mysterious and almost magical spirit of Germany. He afterwards settled in England, and resided there for some years. When he was nineteen years old, he wrote a successful comedy, called 'The East Indian.' The novel by which he is chiefly known, 'The Monk,' was published in 1796; and he has since written many others, showing a skillful employment of supernatural and mysterious agencies, and the display of horrors, it is, perhaps, unrivaled in the English language. A considerable portion of its details are
to the operations of the lustful passions on the character of a man violent and unscrupulous in his nature, but under the restraint of monastic vows. The young novelist drew the character broadly and offensively; and the singular inhumanity of his several crimes, so popular with the taste of novel readers to be extensively circulated, excited much indignation. It is understood that the Society for the Suppression of vice applied to the Attorney-General to take legal steps to prevent the publication of this book, which enlarged the author's fame. At that time it was rather favourable to the success of a work of genius that its morality was not perfectly pure, and Lewis had the satisfaction of being a most popular writer, and the following passage from his poem, as represented in his published letters, is singularly at variance with that which might he derived from the study of his works. He appears to have been good-hearted, simple, affectionate, and not addicted to any vice. He had a very difficult part to maintain in his intercourse with his parents, his mother having, on account of her levities, long been separated from her husband. Although he could not vindicate her conduct, he gave her his kindest sympathies. It is a singular circumstance in his life, that, after having lived for some time on bad terms with his father, the latter dying in a temper which precluded the son from any hope of succession, yet left him, with slight exceptions, his whole fortune. This event made Lewis a rich West India proprietor. He was very kind to his slaves, and his occasional visits to his estates in Jamaica were wrought with the most humane effect. He regarded the slaves and those in the neighbourhood of his estate. His poetical pieces, including 'Alone the Brave,' 'Bill Jones,' &c, are well known: they are distinguished by the fluency of their style and a noticeable closeness of style. He writes as they narrate horrible and tragic incidents. There is, however, in all his writings, a tone of barbarous and exaggerated taste. In 1812, he introduced to the stage the drama of 'Eumorph the Tartar,' which is said to have had much influence in creating the taste for gorgeous pictures, from which the British stage has for some years been struggling to relieve itself. Lewis died at sea, on the 14th May, 1816, when on the way home from a visit to the Continent. (Life and Correspondence of Matthew Gregory Lewis. 8vo., London, 1839.)

LEYDEN, LUCAS VAN, a very celebrated old Dutch painter and engraver, was born at Leyden in 1604. He was first instructed in the arts by Hugo Jacobz, his father; afterwards by Cornelis Engelbrechtsz; and he distinguished himself even as a boy by his engravings, and was a famous painter as early as his twelfth year. He painted in discontinuity a picture of St. Hubert, in 1606, for a citizen of Leyden, the name of Lorhent, who was so astonished and gratified at the excellence of the work, that he paid him twelve guilders therefor. It was cut by Oost, but it doesnot doubtless a very large sum for a picture. Some of Lucas's early engravings are highly prized by print-collectors, and recounted among the greatest rarities of their class: they owe their high value, in a great measure to their peculiar circumstances of their origin, than to any intrinsic merit they may have. They are better as engravings than as works of art. Vasari speaks highly of the prints of Lucas d'Olanda, as he is called by the Italians. He excelled in aerial perspective, but he was far surpassed by his two contemporaries. Albert Dürer and Marcantonio—in correctness of drawing by the latter, and in execution and in drawing by the former. Albert Dürer visited Lucas at Antwerp in 1521, and he makes the following note in his journal: 'I was invited to dinner by master Lucas, who engraves in copper: he is a little man, and is a native of Leyden. This visit was paid during Dürer's journey through Holland. Flanders, and Brabant, for the sake of becoming acquainted with and seeing the works of their various painters. The entry above quoted from the pocket-book of Albert Dürer, fixes the date of the meeting of these two great masters of Dutch art. Mander, who says that Lucas made it when he was about thirty-three years of age, which, according to his own date of Lucas's birth, 1494, would be in 1527.

The artist was a man of very slight and delicate body, and he was clad more like a prince than artists. It was a succession of feasts, and Lucas repeated the entertainment of Middelburg at Ghent, at Antwerp, and at Mechlin. He, however, was not less energetic in his pleasures than at his work, and he indulged during this excursion in a round of dissipation which appears to have lastingly injured his constitution; he was never well afterwards. His own vanity led him to account for this indisposition that he had entered had endeavoured to poison him, and he added to his malady by indulgence and debauchery. He allowed his mind to fall into such a morbid state that his friends for a long time thought he was insane, and a painter, who had been in the last few years of his life in bed, or at least in the sick-room, still, however, working at occasional intervals. He died in 1533, aged only thirty-nine.

Lucas's pictures are esteemed as they are in the old Flemish style, but are among the best works of that school. They are earnest, expressive, deeply coloured, and executed with great care; and are beautiful and highly interesting, notwithstanding their Gothic forms and arrangement: in the perspective of colour they are in advance of their time. The galleries of Vienna, Berlin, Dresden, and Munich possess a few good pictures by Lucas; his own portrait is in the Berlin Gallery. There is a very small curious picture by him in the collection of the Duke of Devonshire, at Devonshire House; it represents a man having a tooth drawn, while a woman is picking his pocket: there is a print of it, of the same size, by Lucas himself, dated 1529. There is a picture of Lucas at Wilton House, and another at the Liverpool Institution. Mr. Rogers, the poet, possesses a pen-and-ink drawing of the artist, done by Cusack in 1649, and in the possessions of the prince himself, is considered by some his best engraving. A picture of the 'Last Judgment,' one of his most remarkable works, is still in the town-house at Leyden. The print of Eulenspiegel, after the rarest engraving in existence: there are said to be not more than five or six of the original extant, but it has often been copied, and the first copy was made in 1644 by Hondius, when the price of the original, even at that early time, was fifty ducats; it is about six and a half inches high and rather better than five wide, and represents a man playing the harpsichord, with two children on his back, followed by a woman who is also carrying a child, and is leading an ass burdened with two panniers in which are three other children; the whole family is preceded by a small figure dressed in a coat, with a stick in one hand and a jug in the other, an owl on his shoulder, and a dog walking before him,—this is Eulenspiegel; it was engraved in 1620. Bartch, who published a distinct catalogue of the prints of Lucas van Leyden, describes 174 engravings by him; in all, including wood-cuts, his prints amount probably to about 2000.

(Van Mander, Het Leven der Schilders; Bartch, Cata
logue Raisonné de toutes les Estampes qui forment l'Oeuvre de Lucas de Leyde, and Peintre Gravreur, vol. viii.; Huber, Geschichte der Kupferstecher-kunst; Van Eynden and Van der Willigen, Geschichte der Vaterlandleute Schilder-kunst, &c.)

LIEBEL, P. C., The Act of 6 & 7 Vict. c. 96, entitled 'An Act to amend the law respecting defamatory words and libel,' has made some alterations in the law of defamation and libel. The Act commences with the preamble.

For the better protection of private character, and for more effectually securing the liberty of the press, and for better preventing abuses in exercising the said liberty, be it enacted, &c. The Act enacted—1. That in any action for defamation it shall be lawful for the defendant, subject to a certain notice in writing therein described, to give in evidence in mitigation of damages, that he made or offered an apology to the plaintiff for such defamation at such time as in the said section is recited, he has made or offered in writing, and that at such time as the section mentions he inserted in such newspaper or other periodical publication a full apology for the said libel, or made such other apology as in the said section is recited.

2. That in any action for a libel contained in any public newspaper or other periodical publication, it shall be competent to the defendant to plead that such libel was inserted without action of law, in a newspaper or other publication, and that at such time as the section mentions he inserted in such newspaper or other periodical publication a full apology for the said libel, or made such other apology as in the said section is recited.

3. That if any person shall publish any libel upon any other person, or shall directly or indirectly threaten to print or publish, or shall directly or indirectly propose to publish, and shall print or publish, a libel upon any other person, and shall either directly or indirectly offer to prevent the printing or publishing of any matter or thing touching any other person, with intent to extort any money or security for money or any valuable thing from
such or any other person, or with intent to induce any person to confer or procure for any person any appointment or office of the court shall, on conviction be liable to imprisonment for any term not exceeding three years. This enactment does not in any way affect any law as to the sending or delivery of threatening letters or writings. (Threats and Treason, p. C. C.)

§ 4. enacts, That if any person shall maliciously publish any defamatory libel, knowing the same to be false, on conviction he shall be liable to two years' imprisonment, and to pay such fine as the court shall order.\[1\]

§ 5. enacts, That if any person shall maliciously publish any defamatory libel, on conviction he shall be liable to fine or imprisonment, as the court may award, but the imprisonment is not to exceed one year.\[2\]

§ 6. makes an important change. It enacts, That on the trial of any indictment or information for a defamatory libel, the defendant having pleaded such plea as in this section is afterwards mentioned, the truth of the matters charged in the manner is required in pleading a justification to an action for defamation.\[3\]

§ 7. enacts, That when on the trial of any indictment or information for a libel, the plea of Non judicium est, or Guilty, evidence shall have been given which shall establish a presumptive case of publication against the defendant by the act of any other person by his authority, it shall be competent for the plaintiff to prove that such publication was made without his authority, consent, or knowledge, and that the said publication did not arise from want of due care or caution on his part.\[4\]

§ 8. enacts, That in the case of any indictment or information by a private prosecutor for the publication of any defamatory libel, if judgment be given against the defendant, he shall be entitled to recover from the prosecutor the costs that he has sustained in the prosecution of such indictment or information; and that upon a special plea of justification to such indictment or information, if the issue be found for the prosecutor, he shall be entitled to recover from the defendant the costs sustained by him by reason of such plea.

This act does not extend to Scotland, § 10. As it was doubted whether or not it did extend to Ireland, this act was extended to Ireland by § 8 & 9 Vic. c. 75.

Defamation and libel were punished among the Romans. The oldest extant rule about defamation and libel is contained in the fragments of the 'Twelve Tables,' which punished both slanderous words and libellous writings. (Cicero, De Repub. De Officiis, C. 33.) The penalty was that the accused should be punished by a fine of six talents (in the Roman sense of that term), and it appears to have been death. Libellous writings were generally denominated 'famosa carmina' and 'nulla carmina.' In course of time the Praetores of Rome were allowed to impose the old law, or a penalty on those who used such. The praetor allowed an action for slander which was against 'boni mores' (Dig. 47, tit. 10, s. 15); and against 'boni mores' means, that which was disapproved of by the community, and tended to bring injury or odium on the person against whom it was directed. 'The technical word for this kind of slander was Convicium, which properly meant something said to a man's face that was injurious; but the commentators on the Edict laid it down that there might be Conviciun even if the person against whom it was directed was not present. Conviciun in fact was personal abuse which tended to damage a man, and was said with circumstances of great publicity. But the Praetor's Edict extended to other cases, and allowed an action wherever a man had done or said anything which injured a person's character. This general clause included libellous writings, and many other things, such as certain modes of solliciting women's chastity, and addressing them in obscene language. The penalty in all these cases was a sum of money assessed by Reperptores as damages.

Under the Imperial government the term 'liber famosus' often occurs: it signifies any writing in prose or verse which tended to injure a man's character (ad infamiam aliæque). The offence consisted in writing the libel, spreading it about or giving it to another. The punishment was to lose things (dolo malo); it made no difference whether the libel was anonymous or had a false name to it. The penalty was (according to some law, the name of which is not known), that the libeller, if convicted, became intestate, that is, he could not make a will or be a witness to a will. (Dig. 28, tit. 1, s. 16.) A senatus consultum extended the penalties to printing false books and pamphlets, but not writing, but only marks which were of a like tendency; this must mean drawings and caricatures, such as are now published in London. Everything therefore which tended to the 'infamia' of a person, even in the nature of untruth, was liable to such a penalty. If a man was mentioned or not mentioned, provided the person intended was clearly pointed at by such writings or drawings, were punishable offences; and writer, draftsman, and all concerned were liable to the legal penalty.

This legislation seems to belong to the Imperial period, though it was not intended to protect the emperor only. Augustus commenced this legislation (Sueton. Octavia, 55), and precision this device was used in the trial of a chief officer of Roman Caesar, like other high personnages in modern times, were the objects of pasquinades and various kinds of compositions which were intended to satirize and make them ridiculous. The penalty of the law of Augustus is not certain; but in later times various Senatus consults increased the penalty to Deportation or perhaps only reeligation. If the author of a liber famosus had been punished in a criminal prosecution (Judiciwm, libellum, the injured person might still have his action, if he was mentioned by name in the libel. (Dig. 47, tit. 10, s. 6.) But if a man libelled a guilty person (nocens), it was considered equitable that he should not be subject to penalties for his error, as this would be an evil-doers ought to be known, and it was expedient that they should be known.' Compare the 6 & 7 Vict. c. 96, § 6.

The 'libri famosi,' or 'libelli famosi,' of the Imperial period, signified anonymous writings, which contained a charge against some person, and were either sent to the Caesar or to some magistrate, or put in some place where they might be found, for the purpose of casting injury on the person accused. This is the only signification of the expression 'libelli famosi,' in the Thedosian and Justinian codes. Constantine the Great declared that such charges should not be prejudicial to any person, and that such writing should be burnt when the author was unknown. If the author was discovered, he was punishable even if he could prove the truth of the matter contained in the writing. Other constitutions on the same subject were made after the time of Constantine.

(Rein, Das Criminalrecht der Römer.)

LIBELLULA, the genus of insects which includes the well-known Dragon-Flies. It belongs to the order Neuroptera and to the section Subdiptera in the arrangement of Latreille. The dragon-flies are often called 'Libellulas' by naturalists. The dragon-flies are generally divided into two genera covered by the labrum and labium; their tarsi are three-pointed; their wings are equal; the posterior extremity of the abdomen is furnished with hooks or peculiar appendages. The size of these insects varies from 2 to 3 inches. They fall into various families and are very useful to the farmer, as they have various beneficial results. They are injurious to many useful insects, and are a period of activity and locomotion. They are then furnished with an extraordinary mask formed out of that part of the head which replaces the lower lip, and by which they cover the jaws and the whole under part of the head. They use it to aline and seize their prey, projecting it at will. When perfect insects, they become inhabitants of air, and are endowed with extraordinary power of flight and precision of movement, performing astonishing evolutions. Their habits continue as ferocious as they were before. When taken and imprisoned, they have been known to devour their own bodies! Several valuable monographs have been published on these interesting insects. Monographie des Libellulides d'Europe. 61 species are described, arranged under the genera Libellula, Cordulia, Linnea, Onychophorus, Cordulga, Orthoptera, Eborus, Anura, Coleoptera, Lepias, Sympron, and Atraphates. (In the chapter devoted to the modern Classification of Insects) the genera of Libellulidae inhabiting Britain are grouped under two sub-families, Libellulidae and Agrionidae. The following table exhibits the chief characters of the British genera:—

by the circumstance of his becoming free that he became a citizen, though positive law, as among the Romans, might limit the degree in which he thereby obtained citizenship.

Corveks, P. C., says that the difference between freedom and slavery was not based on the idea of antiquity which were under monarchical or tyrannical rule; but he who was the slave of an individual in any such state, and obtained his freedom, did not thereby become a citizen, but was merely released from the duty that he owed to his lord; he sold himself to the master: he still owed together with others the duty of perfect obedience to an individual monarch or tyrant.

The words liberty and freedom, as political terms, have always been used to express the condition of a people in which they are to some degree at least secured against the arbitrary rule of an individual or of a small number of persons; and the word slavery, in a political sense, is applied to nations in which the mass of the people have no tolerable security for their lives and property against the capricious rule of one man or of a number of persons who form a small minority of the whole.

That which is really meant by political freedom and liberty is nothing more than a form of government which shall in some degree at least secure to the people the enjoyment of life and of their property against the tyranny of one man or of a few. Freedom and liberty then are terms which can only be applied to constitutional governments [Constitution, P. C.], and to republics, in the proper sense of that term. There is no political liberty or constitutional rule under any other form of government. This is the case even with free commonwealths, of which political liberty is derived from the very formation of a nation, though under a monarchy, when the administration is good, there may be in many respects more personal freedom than there is in a pure democracy. But the essential quality by which free commonwealths are distinguished is this: the sovereign power is not in the hands of one or of a small minority, but it is either distributed among the whole community or a considerable part of it.

Political liberty does not exist in some civilized nations in Europe, in Prussia for instance. Political liberty does not exist in Russia. In some countries where it does not exist, it is the general opinion that its existence would be a benefit to the people. In certain nations, the people are still in such a condition that political liberty could not exist, for political liberty, as already stated, means that the sovereign power must be in the hands of a large number, and they must possess intelligence enough to enable them to exercise and keep the power; but there are nations where the mass of the people are too ignorant to exercise or keep any political power.

The highest degree of political liberty is in a Democracy [Democracy, P. C.]; for it is that form of government which is furthest removed from a monarchy. The relationship of monarch and subject is the like relationship to master and slave.

A nation which strives for its liberty strives for a popular form of government, whether it be a constitutional kingly form of government or a republic. Liberty is a species of democracy, is understood; and many who have cried out for liberty have either not considered exactly what it is they want, or they have supposed that liberty would free them from many evils which they consider to be peculiar to a state governed by a monarch. It is now generally admitted, that in those states where a large part of the population have equal political knowledge with the few, who direct administration, the general interests are best served by this large number participating in the government. Political liberty then, to some extent or degree, is, in many countries, necessary for securing the advantages of good administration. But there are many evils incident to states, which are not due to the want of political liberty; and it is therefore a matter of importance for those who would make changes in government to consider whether the evils of which they complain are owing to the want of political liberty or to other causes.

The notion of political liberty has been based upon the analogy already pointed out between Political Liberty and Personal Liberty; which is a false analogy, though an historical one. Man is naturally a solitary being, and nature is not due to the want of political liberty; and it is said, arises from the want of government. On these assumptions rests the American Declaration of Independence: "We hold these truths to be self-evident: that all men are created equal; that they are endowed by their Creator with certain unalienable Rights; that among these are Life, Liberty, and the pursuit of Happiness; that to secure..."
these rights governments are instituted among men, deriving their joint powers from the consent of the governed, &c.

In this passage Liberty appears as a thing distinct, which is opposed to slavery, and it is on the assumption of the equality by birth and the endowment of all men with certain inalienable rights, that this instrument would found the American title to liberty. It is the doctrine of the social contract, and assumes, as an historical fact, an origin of governments by consent of the governed. It was also promulgated in a country in which a very large number of free negroes, mulattoes, and still slaves; and they governments have been constituted without the consent of the governed. These are real facts: those assumptions are untruths.

Political liberty rests on no such sorry basis as the Declaration of Independence places it on. That nation which can obtain it and maintain it is in a better condition than if it were politically a slave, even to the wisest of masters; and when it is able to obtain and maintain that liberty, it is right, or in other words it is for the general interest, that a nation should, by force if necessary, alter that form of government which is political slavery.

The Republican promise to be most stable which is the growth of long time and the result of a perpetual struggle between a master and his slaves, in which the master has not ceased to be master all at once, but has always lost something in the contest.

That which is of sudden growth or is the offspiring of Revolution, is often premature, and always insecure; so liberty so acquired may only be a step from a state of political slavery to a more wretched state; it may be a step, from a state of slavery, mild and tolerable, to an anarchy, of which all things is most intolerable.

The words Liberty and Equality often go together, and each is in some doubtful a sense that one hardly knows what to make of them. Liberty is often used, apparently without people considering what they really mean, in the sense of freedom from restraint. But this kind of Liberty is inconsistent with Political Liberty properly understood; and all men's liberty of action is and must be restrained by positive laws in every well-ordered community. Every law that forbids any act directly or by implication abridges Liberty, and such abridgment is always a universal benefit when the law which so abridges liberty only abridges it in cases where it is useful to all that it should be abridged, and where the law is so framed as to accomplish that object. Equality, in its unlimited sense, can no more exist in any state than perfect individual liberty; for if each man is left to exercise his industry in the best way that he can, without interfering directly with the power of the one individual some will be richer, and wiser than others. The only Equality that can be approached to in a well-ordered state is that Equality which is the result of a good polity, which polity, so far as it is consistent with the universal good, secures to every individual in the State the free enjoyment of his industry, wealth, and talents, imposes restraint on all alike, and makes all alike bear the burden of taxation and of the services due to the State. Further, it gives to us as large a number as it can, consistently with the universal interest, an equal share in the sovereign power; but no polity that has ever yet been framed has ever given an equal share in the sovereign power to all the members of a community; such an Equality is impossible.

The Declaration of Rights published by the French National Assembly in 1789 contains the words 'free,' 'equal,' 'rights,' 'liberty,' and many others, all of which are used in a sense remote from precision as the most confused understanding could suggest. This strange sample of nonsense has been examined and dissected by Bentham in his 'Anarchical FALLACIES' (Bentham's Works, part vii, Edinburgh, 1823).

The word Liberties is often used to express those particular constitutional principles or fundamental laws by which the political liberty of a nation is secured. If the British parliament wishes to be held in the right hand, or the Habeas Corpus, such an attempt would be called an attack on the liberties of Englishmen.

LIGAMENTS, ANAT., F. C.

LIGAMENTS are bandages, and organs by which the various articulations of the animal body are held together.

[ARTICULATION, P. C.] They are generally very strong membranes, and in their structure and composition resemble greatly the cartilages. There are several kinds, and in the following examples, they are attached to two bones, and assist in the formation and strengthening of the joints. Ligaments are of various forms: some completely enclose the joint as in a case or capsule, and are called connexions; others form straight bands passing from one bone to another; whilst others, again, are inserted into the heads and cavities of bones within the joint. For the names of the various ligaments and their functions forming the ligaments see THORAC, ANIMAL, P. C. S.

LIGHT, ABSORPTION OF. [Absorption of Light, P. C. S. 714]

LIGHT-BALLS, for military purposes, are hollow cases, either spherical or in the form of cylinders, terminated at each extremity by a hemisphere: they are filled with a combustible composition, and being thrown, by night, in a burning state from mortars, or in some cases from the hand, they serve to discover the working-parties or troops of the enemy.

The spherical cases are made of canvas or cartridge-paper, cut into eight equal gorses of a proper form and the edges sewn together, a hole being cut in the introduction of the composition and the application of a fuse. The oblong cases consist, frequently, of two hollow hemispheres of iron, which are connected with each other by four slender bars of iron attached to the inner surfaces, in position to the body of the case, and the whole is then covered with canvas: the entire length is about 14 calibre of the piece of ordnance from which the ball is to be projected,—a mortar of one of the four different kinds, with cases varying from 4 inches to 10 inches a boiling state; and sometimes a small quantity of mealed gunpowder is added. The oblong balls are filled by passing the composition through a fuse-hole in one of the hemispheres, and are afterwards, when strengthened by cord with a load of gunpowder or oil, are filled with a combustible composition. A charge of fire is communicated to either kind of ball, at the time of being projected, by means of a piece of quick-match in the fuse.

Previously to besieging a fortified place, the works and the ground about them are reconnoitred, usually by; the first trenches are also traced and formed during the hours of darkness, and therefore the defenders, at the commencement of the siege, prepare some mortars charged with light-balls: these balls being thrown beyond the glacis, enable them to discover the operations of the enemy, and direct a fire of shot against them. The assualt of a breach is also frequently made by night; and in this case light-balls should be thrown by the defenders into the ditches of the place for like purposes.

These may be made by merely filling grenades with the composition, through the breech, and then firing it by the same means as a shot.

Major-General Sir J. T. Jones states (Journal of Siege), that the defenders of the towns which were besieged by the British army in Spain threw light-balls in order to discover the operations of the enemy, and to project a flame of oil and pitch. The engineers' brigade were kept in readiness to run up and extinguish them as they fell. That officer adds that the men generally succeeded, in a few seconds, in extinguishing them with filled sand-bags, or by throwing earth over them. Some casualties are stated to have occurred among the men so employed; but the fire of the enemy being directed against them, they were thereby diverted from the working-party often employed at a great distance from the breach. On account of the great utility of such balls for illuminating the ground occupied by the enemy, Sir J. T. Jones recommended that grenades or other missiles should be connected with them by pieces of cord. The name was suggested by the fact that the men might be deterred from attempting to extinguish the light.

It may be added that spherical cases of pasteboard or canvas filled with a composition which while burning emits a great quantity of light, and smoke, are frequently used in mortars in order to conceal a movement of troops from the view of the enemy: they are also occasionally thrown from the hand either to suffocate the men employed in the galleries and breaches, or to set the fire to the houses in all the cases are called smoke-balls. The composition consists of mealed powder (6b.), pulverized saltpetre (1lb.), pulverized seaweed (1½ lb.), pitch (2½ lb.), and tallow (4 lb.); the pitch and tallow are melted together, and the dry materials, after being sifted, are mixed with the liquid.
L I G

LIGHTHOUSE. [Sect. Laws, P. C. S.] A Light-house is a structure which gives the right of enjoy-
ment of free access of light to a man's premises or buildings, which right must not be impaired by the building or erection of any object in such a way as to obstruct the light. By the 2 & 3 Vict. c. 40, tit. V., sect. 19, the right to light given to a man, who has more than twenty years' uninterrupted enjoyment, unless the use has been enjoyed by some consent or agreement made or given by deed or writing.

When a right to light has been established, he who occupies or owns the adjoining land cannot build in such manner as to obstruct the light. If such obstruction is built or erected, the person who is injured has an action on the case: and the Court will not, if the building is erected in 1842, or afterwards, without the consent of the owner or occupier, declare a person to be in default, merely because the building obstructs the light. The object, therefore, is to prevent the building or erection causing such a privation of light as to be an illegal act.

The right to the free enjoyment of Light belongs in the Roman law to the class of Servitii (essemens), among which were the Servitii a lumen non condendi, those in common officiari, ne prospectus officiari (Dig. 8, tit. 2, s. 3, 11, 12, 15-17). The general rule is thus expressed by Ulpian: 'If the owner of the building by his light, or by doing anything else to damage them, must not be held for the obstruction of the light. But he will have it to the time of your neighbour's light is to be extinguished; and if you and your neighbour cannot agree about the height to which the light shall go, if you begin to erect, you will have the privilege of having an arbiter.'

It is said that according to the English law the stopping of a prospect is not a nuisance. The Roman law, as already observed, allowed a Servitius ne prospectus officiari. The Roman rules of law as to essemens in general are more precise than those of the English law.

LIGHTS, ARTIFICIAL. Within the last few years many new inventions have been introduced for the illumination of apartments—by candles, by lamps, and by a sort of combination of both. The modes of illuminating large buildings have been explained in Gas, P. C.; Bond Light, P. C. S.; Drummond Lights, P. C. S.; while the articles Alard, P. C., and Candles, P. C., illustrated the common modes of domestic lighting. The recent inventions may be classified at 1. Candles; 2. Candeleo-Lamps; 3. Oil-Lamps; 4. Spirit-lamps. 1. Candles. Dr. Ure, in the Supplement to his 'Dictionary of Arts,' describes the mode adopted by Messrs. Hempel and Blandell, for making candles of palm-oil, maragric acid, and stearic acid or stearine. The palm-oil is melted in an iron pan, and then cooled gradually, by which it is separated into a liquid oleine or oil, and two solids, stearine and margarine. The oil being kept in the sun until it becomes nearly saturated with quicklime, and the mixture is afterwards brought to a crystallized state by the action of cold water. Muriate of lime and sulphuric acid are then employed to separate the quicklime from the oil. The quicklime being washed and dried, is then cooled, and crystallized, are pressed, whereby the stearine is separated from the margarine. The two are separately heated, and the stearine goes through further refining processes, until it assumes the form of a pure and solid kind of palm-wax or hardened tallow, fit to make into candles in the usual way. The margarine, or margaric acid, obtained in this way, is mixed with common tallow to make another sort of candles.

Palmer's candles differ in many points from those in common use. In a patent obtained for them in 1842, one of the arrangements was intended to make the wick bend out of the flame, so as to come into contact with the atmosphere, and thereby render the troublesome process of 'snuffing' unnecessary; this consisted in impregnating one side of the wick with common starch or starch, which gave a greater stiffness and less combustibility to that side of the wick than the other: this inequality of action gave a bending tendency to the wick. The same object is, however, now attained by having the wick in two halves, twisting spirally round each other; each half is bound round in a tolerably compact form, and the process of extinguishing the spiral, by the gradual burning of the candle, causes the tops of the wicks to spread out laterally beyond the boundary of the flame. The carbon or ash is not conveyed to the lower end of the wick, but accumu-

The circumstance of palm-oil being in a solid state in our climate, coupled with an ascertainment of mode of separating it into three different substances, has led to many suggested variations in the mode of making candles, by the mixture of one or more of these component substances with the oil, or the use of certain kinds of animal fat. There have also been patents taken out for new varieties of wick, and new forms given to the candle; but these do not involve any features which call for much notice.

2. Candle-Lamps. A Candeleo-Lamp is a designation under which may be grouped many recent contrivances, having for object the burning of solid tallow or fat instead of oil, but without having the tallow formed into a candle.

The Soho lamp, patented in 1842, is used for burning solid tallow or some other kind of fat; although the lamp itself is very similar in shape to many of those used with oil. The tallow is brought to the form of a long cylinder like a candle without a wick, and is placed in the vertical stem of the lamp; there is a spring spring beneath it, which presses it up close to a conical cap or cover at the top. A fixed tube passes up through the centre of the cylinder of tallow, from top to bottom; and the lamp is kept in position by means of a wire, which, at the lower part, is fixed loosely within the lamp, and at the upper part, is fixed tightly to the conical cap or cover of the lamp. When the lamp is lighted, the wick is drawn down below the top of the tube, and again raised before the tallow becomes cold.

The lamps or contrivances now made for burning Palmer's candles, and which are indeed fitted for most kinds of candles, bear a good deal of resemblance to the above, in respect of having a conical cap to keep the candle within the tube, and a spiral spring in the lower part of the tube to press the candle upwards as it burns; but there is no necessity for the central wick tube, since the candles employed have wicks of their own. These candles, and the candles belonging to them, offer the two conveniences of maintaining the light always at an equal height, and of dispensing with the aid of the snuffer. Some sort of shade or globe is necessary for realizing the latter of these two benefits fully; since the flame becomes very un-

One of the projects of this class consists in placing any kind of wax or tallow or fat into a receptacle, and giving either hot water or hot metal beneath it, so as to keep it in a melted state, fitted to be used in the same manner as oil; but any method of keeping the water or the metal hot would seem likely to be a far greater inconvenience than any supposed good arising from the use of a solid form for the lamp. In the preliminary contrivance, however, where the substance employed is either tallow or fat, there is a piece of metal which descends from the flame into the vessel containing the latter; and this metal, being gradually cooled and crystallized, is pressed by the weight of the metal enclosed in the vessel, which is heated by the lamp, and thus kept in a melted state. The inconvenience of such arrangements arises from the circumstance that the hot water or a heated piece of metal must be put into the lamp before lighting it, and it must be taken out of the lamp before it is extinguished. A preliminary step is taken, the tallow is kept in a melted state by various means. One ingenious mode consists in having an air-tube within the wick, to carry air up to the flame, and two projections from this tube at the top, into the flame itself; so that the metal of which the tube is made, becomes heated at the upper end, speedily communicates heat to the contents of the lamp below.

There are many curious little pieces of mechanism, patented within the last few years, the object of which relates principally to the burning of common candles, or the mode of adjusting them to the candle-sticks. One consists of a candle-stick constructed in a circular ring, which rings are suspended from a conical cap which rests on the top of the candle; as the candle burns, this cap sinks with it, and the length of the candle is kept at the same height as the level of the flame, though not relatively to the level of the table on which the candlestick is placed. Another contrivance is intended to afford the means of adjusting any candle, large or small, to a large candlestick, by having a semicircular piece of brass, which is made to press against one side of the candle in the socket. A similer contrivance for the same object consists of a pair of wedges, placed one on either side of the lower end of the candle. A part of the same apparatus consists of a wire-frame for supporting a shade, and which is itself supported by having a sort of circular spring hoop, which clamps the candle.

3. Oil-Lamps.—One of the difficulties which have arisen in L 2 D 2
the usefulness of common oil-lamps is the tendency of the oil to thicken in cold weather; while another lies in the imperfection of the means for keeping the wick well moistened with oil up to the verge of the flame. Both of these matters have engaged attention within the last few years. Dr. Ure remarks (p. 184.), "The lamp manufacturer can no longer afford to use even stearic candles, as also the nuisance of the light from tallow ones, have led to the invention of an endless variety of lamps, of which the brighter kind is undoubtedly the mechanical or Carcel lamp, so generally used by the affluent families in Paris. In this lamp the oil is raised through tubes by clockwork, so as continually to overflow at the bottom of the burning wick, and hence to prevent the flame from puffing, while the excess of the oil drops back into the citeron below."

There is a lamp called the Meteor lamp, having some of the properties of the Carcel, but intended for burning rape-oil. The internal arrangements of this lamp are curious and complicated. The lower part of the pedestal consists of a reservoir for containing the oil; and in this reservoir is a kind of piston or plunger, worked up and down by a nut and screw from the outside; the rising of this piston occasions the escaping or tightening of a coiled spring, and this pressure causes the oil to be forced up a central tube towards the flame. The admission and regulation of the oil to the lamp, the adjustment of the wick, is made by the piston; of the damping, and of the gallery which supports the glass chimney, are all of an intricate kind, and, whatever may be their efficiency while in good order, would render the repair, in case of accident, a matter of much difficulty.

One of the modes adopted for maintaining the oil in a liquid state, is by the use of a lamp constructed by Mr. Parker, in which the oil is used in a hot state. At a small distance above the wick, there is a tube, the lower end of which is connected with the bottom of the reservoir, while the space between the two tubes, of capacity sufficient to hold a pint, constitutes the reservoir for the oil. The oil is thus near the flame, that it speedily becomes warm, by which its facility of burning is much increased; and this, together with the pressure, causes the oil to descend from the reservoir to the wick. The intensity of the flame is modified by raising or lowering a slide on the lamp, by means of a rack and pinion mechanism. In a series of experiments on the illuminating powers of different kinds of lamps and candles, Dr. Ure found that the hot-oil lamp, with a given quantity of oil, gave a brighter light than any other form of lamp; or, the light being equal in intensity, the hot-oil lamp was the most economical. This corroborates, so far as it goes, the remarkable results obtained by the hot-blast in the iron manufacture.

Argand's principle of the mode of admitting air to act on the wick has been the one most generally followed since his time; and many of the subsequent inventions have had relation merely to some modification of this arrangement. The Scotch Argand, according to Dr. Ure (p. 175.), allows air to pass up through the interior of the wick, as in the Argand; but the action of the air on the exterior of the wick is made more decided. The wick passes through a hole in the centre of a cask, which is fitted with a cap or close to this hole, and in a horizontal direction, while the flame is yet small; so that the exposure of the gaseous products to the air is much more intimate than in the ordinary lamps, and the combustion more complete. Many improvements have been introduced from time to time, but the solar lamp remains in principle an Argand, with the addition of a cap or dome to direct the external air more directly upon the flame. Many of the modern variations in lamps and in gas-burners have had relation to this circumstance of admitting the external air to act at the points and in the quantity found best for the maintenance of the flame.

4. Spirit-Lamps.—In chemical experiments the spirit-lamp has long been a valuable piece of apparatus; but the use of spirit instead of oil, as a food for lamps intended for domestic purposes, is a modern innovation, and has led to much mechanical ingenuity in the construction of the apparatus.

The term "spirit" is rather a vague one, since there are many kinds of spirit which are inflammable enough to be used for this purpose; but the kind here alluded to is the spirit of turpentine, or that liquid which is distilled from common turpentine by being separated from the resin which is a component ingredient in this well-known substance. When brought to its purest state, this spirit is called by the chemists camphine; and hence the name for some of the modern spirit-lamps. Turpentine being a very abundant produce of the American forests, camphine has been long in use in the United States for lighting shops and public buildings; and it seems to have been from that country that the practice was borrowed and introduced into England. When the import duty on turpentine was lowered two or three years ago, the price became reduced sufficiently to direct the attention of lamp-makers to the practical utility of using camphine as a substitute for oil. Many different lamps have resulted from these inquiries; and different processes have also been adopted for freeing the turpentine from a small quantity of oil in which it commonly appears.

Young's "Vesta" lamp is one of these varieties. In the specification of the patent it was stated that the lamp is constructed for burning rectified spirits of turpentine, or camphine; that, on the removal of the stop-cock, sufficient of this liquid, provision is made for keeping cool the reservoir where it is deposited; that no tube or metal conductor of any description is allowed to pass into or through the liquid from the burning part of the lamp; that a non-conductor of heat is placed between the burner and the liquid; that the cotton wick hangs down from the burner into the spirit, so as to supply spirit to the flame by capillary attraction, without the intervention of any metallic or conducting substance; that the admission of air to the interior of the wick is managed without the necessity of passing an air-tube through the liquid. All these features and a few others are rendered necessary in the camphine or spirit lamps, on account of the liability of the liquid to evaporate, and the probability such that the arrangements for an oil-lamp would not be available for a camphine-lamp without much danger.

Whether these camphine-lamps receive the name of "Vesta," or "Gren," or "Parker," or "Paragon," or "Spermaceti," or any of the many which have been applied to them, they all present in common a reservoir, generally of glass, placed between the supporting pillar and the burner; the spirit is contained in the reservoir, and is supplied to the burner by means of an air-tube. The chief points in which the several varieties of the lamp differ are in the arrangements for admitting air to the flame.

Of one of these lamps, the "Vesta," Dr. Ure states, that if "burning be an unalloyed pleasure," it emits a light equal to very nearly twelve wax or sperm candles of three or four to the pound; and in so doing it consumes exactly one-twelfth of the value of wax (value sixpence) in ten hours; hence the cost per hour for a light equal to ten such candles is one halfpenny. Since that statement was written, the demand for camphine has raised its price, and the relative advantages in its favour are therefore smaller; but it still remains much cheaper than any form of candle or of oil-lamp, in relation to the quantity of light yielded. All lamps-contain some oxygen, which neutralizes a part of the hydrogen and carbon, and also some oxide or other substance which damps the brilliancy of the flame; whereas rectified camphine, being composed almost wholly of hydrogen and carbon, contains nothing but what is susceptible of combustion. A lamp, therefore, while it emits no foot combustion, and also so as to avoid danger, are questions for the manufacturer; but in a scientific point of view, camphine seems better fitted for combustion than oil. It is not necessary that the flame should be done from the same source, but it is necessary that it should not drip; and the oil lamp is effective on this account. The chief danger is that subjected to careful distillation and rectification, will yield a spirit or camphine differing but little from that yielded by turpentine.

A few words may here be added concerning two important features connected with lamps, viz. the comparative illuminating powers of different kinds, and the means of carrying off the product of combustion.

Pecquet, Dr. Ure, and Dr. Frye have all instituted experiments bearing on the former of these two questions. Pecquet experimented on candles only. He determined what would be the value of different kinds of camphine, in producing a given intensity of light, as determined by Carrel's lamp as a standard. They rank in the following order, the first being the cheapest:—tallow candles, six to the pound; ditto, of eight to the pound; pressed tallow; stearine; spermatici; wax. This relation was as to price only; the relative weights of material consumed followed a different order of arrangement, the spermatics being the least, and the pressed tallow the greatest. In Dr. Ure's list ( 'Supplement to Dictionary of Arts') the relative quantities of light for a given price, or the relative cheapness of a given quantity of light, among several kinds of lamps and candles, are placed in the following order:—To have the same effect as:

- Black-oil, or Hot-oil lamp, with spermaceti; or, with common olive-oil; or, with coconut-oil;
French lamp, with sperum-oil.
Mould tallow candles.
Palma-oil, and sperum candles.
Stearic acid candles.
Cocoa-nut stearine.
Spermaceti candles.
Wax.
the first being, in point of economy, the cheapest, and the last the dearest.

Dr. Fyle's experiments ('Transactions of the Royal Scot.

tish Society of Arts') seem to have been of a more extensive
character, embracing a larger number of sources of illumination.
Assuming a given intensity of gas-light as a standard, he experimented on ten varieties of candles, and found their relative cheapness, in the proportion that the light was produced, to rank as follows:—tallow with single wick, cocoa, composite, palm, tallow with double wick, wax, diaphane, margarine, spermaceti, and composition. In another table, comparing gas with candles, he ranks palm wick third, and the following intensity of light being uniform:

**Argand gas-flame** 1:00
**Solar lamp** 2:00
**Naphtha** 3:00
**Solar oil in Argand lamp** 3:98
**Whale-oil** 5:00
**Sperum-oil** 8:00
**Tallow candle (two wicks)** 12:70
**Cocoa candle** 13:10
**Tallow candle (one wick)** 13:50
**Composite** 14:50
**Balm** 18:90
**Wax** 25:90
**Diaphane** 27:10
**Margarine** 29:20
**Spermaceti** 29:20
**Composition** 29:20

According to this table, composition candles are nearly thirty times as cheap as gas for an equal intensity of light.

Dr. Faraday has introduced an important arrangement for carrying off the products of combustion in gas and oil lamps. This arose out of a complaint, on the part of the members of the Alexandra Club, that the dearth of stamens was vitiated and the hindering of the books injured by the lamp then used. Dr. Faraday investigated the subject, and shortly afterwards communicated to the Institute of Civil Engineers the mode which he proposed to adopt for remedying the evil. In a paper communicated to this body (Session 1843) he adduced striking proof of the magnitude of the product resulting from combustion. Oil and gas each contains carbon and hydrogen, and each has an attraction for oxygen to bring about combustion. The light is one of the indications of the intensity of this union; and the substances which result from it are mainly two—water, by a combination of some of the oxygen with the hydrogen of the oil or gas; and carbonic acid, by the combination of more of the oxygen with the carbon. The quantity of these two substances produced, owing to the enormous absorption of oxygen during the combination, would by many persons be deemed quite extraordinary. A pint of oil, when burned, produces a pint and a quarter of water, and a pound of gas more than two and a half pounds of water; the increase of weight being due to the absorption of oxygen from the atmosphere, one part of hydrogen taking eight parts (by weight) of oxygen to form water. A London Argand gas-lamp, in a closed shop-window, will produce in four hours two pints of water and a pound of oxygen gas also produces nearly three pounds of carbolic acid, and a pound of gas two and a half pounds of carbolic acid. For every cubic foot of gas burned, rather more than a cubic foot of carbolic acid is produced.

As the water produced deadens the effect of the flame, and as the carbolic acid is very deleterious to the lungs, Dr. Faraday contrived a mode of carrying both off without allowing them to mix with the air of the room. A tube is admitted to feed the flame, nearly in the usual way; but when the products of combustion have arrived at the top of the glass chimney, their progress is arrested by a covering of tare, and they are completely passed down between the chimney and another larger glass chimney concentric with it. The open space between the two chimneys communicates with a pipe which is conducted in any convenient way into the open air; the carbamic acid, aqueous vapour, smoke, and other emanations from the flame have no means of escape except through this tube, and they are thus wholly cut off from contact with the air of the room. The mode of carrying off the arrangement may be varied in its details; but the general result is said to be that the light is brighter, the space around the lamp cooler, and the air in the room less vitiated than when common open burners are used.

**LIGUZZI, JA/COPO,** a distinguished Italian painter in fresco and in oil, was born at Verona, in 1643, and studied under Paolo Veronese. He established himself at Florence, where he had much influence upon the painters of his time, especially in colouring, for though not equal to Paolo Veronese, Liguozzi was an effective and powerful colourist, and at the same time that he displayed vigour in the colouring of the Florentines, he improved his own drawing. The Grand Duke Ferdinand II. appointed Liguozzi his principal painter, and superintendent of the Imperial Gallery. He died in 1697.

Liguozzi is the painter of several grand works in oils, though they are what the Italians call quadri di macchina or machines, that is ornamental or decorative works, distinguished chiefly for their size and effect on a large scale. The following works, however, are of a superior order of this class—San Raimondo resuscitating an infant, in Santa Maria Novella; the four crowned Saints,—Sts. quattro Coronati—at Ghi Scalzi; or the barred friars, at San Lorenzo, and the Martyrians of Santa Dorothy, at the Conventual Friars, at Pescia. Liguozzi executed also many small highly finished easel pictures. Agostino Carracci engraved some of his works. (Lanzi, Storia del Arte, etc.)

**LIGUSTRUM,** a genus of plants belonging to the natural order Jasminaceae. It has a flaxly fruit, the berry containing two mesomalous one-seeded nuts. The calyx is short, tubular, and four-toothed; the limb of the corolla 4-petalled and spreading; stamens 2, with short filaments. The species are shrubs or low trees, natives of Europe and Asia.

**L. vulgaris,** Common Privet, has elliptic lanceolate phloem leaves; compound racemes; white flowers; white at first, but soon changing to a reddish brown. The berries are dark purple, almost black. It is a husky sub-evergreen shrub, growing in hedges and thickets in Great Britain, and native of the South-west of England. This plant was formerly called Prin, or Prinvum, from its being used for verdant sculptures, or topiary-work, and for primly cut hedges. The common English name Privet seems to have been derived from this, from its being frequently planted to conceal private places. In German, Dutch, Danish, and Swedish it is called Ligustrum; in French, Troupe; in Italian, Ligustro; in Spanish, Afena; and in Portuguese, Afnha. It is probably the Epstein of Theophrastus, ' Hist. Plant.' 1, 14. In point of utility and ornament few shrubs exceed the privet. Its chief use is to form hedges either for shelter or ornament. It bears cutting well, and it is not liable to be damaged by frost or disease, and robins the grass less than almost any other shrub. It is one of the few plants that will grow in the smoke of London; it also thrives under the dripping of other trees. The wood is hard and fit for timbers; the oil of the leaves is a very subtile and coloured pigment may be prepared; with the addition of alun they dye wool and silk of a good durable green. The following varieties are those found chiefly in our gardens:

- **L. v. luscorum,** the weaver-rod privet, or Sinhance.
- **L. v. chinocarpum,** the yellow-berried privet.
- **L. v. chlorocarpum,** the green-berried privet.
- **L. v. sempervirens,** the Italian or evergreen privet.
- **L. v. sargiogenum,** the variegated-leaved privet.
- **L. v. austriofolium,** the narrow-leaved privet.
- **L. Sinensas** has lanceolate tomentose leaves, white flowers, and very small brown berries. It is a native of China, near Canton.

**L. japonicum** is a native of Japan, with oblong ovate grooved leaves, and white flowers growing to the height of six or eight feet.

**L. spectum** has elliptic acute leaves, hairy beneath, as well as the branchlets. Flowers crowded, almost sessile, spicate, disposed in a thyrse, having the axis very hairy, and covered with minute bristles.

- **L. spectum** has broad leaves, growing on mountains, from six to eight feet in height. All the species of Privet are of easy culture, and will grow in any kind of soil. Cuttings root without difficulty. **L. buchhoms** requires some protection in the winter. (Don, Gardner's Dictionary; Babington, Manual of British Botany; Eras, Syrosous Flora Classiosa; Loudon, Encyclopaedia of Trees and Shrubs.)
LILAC. (Strinsa, P. C.)

LILITUM (the Latin Liliatum, and Greek λιίλιον,) a genus of plants the type of the natural order Liliaceae. It has a perianth of six leaves spreading or reflexed, with a longitudinal nectariferous furrow at the base of each; an undivided ovary, free or united, and perianth-like stigmas, and flat seeds. The colour of the flowers is either white, yellow, or red.

L. candidum, common White Lily, has lanceolate scattered leaves, a bulb with a shallow smooth corolla, the petals of a beautiful shining white on their inside, ridged and not quite so transparent or luminous on their outside. The flowers are large, white, and in a cluster at the top of the stalk, solitary or in pairs, and has been cultivated in our gardens from time immemorial. Great doubts had existed respecting the native habitat of this species, till Mr. Hawkins, the friend and companion of Dr. Sibthorp, found it growing wild in that classical and celebrated spot the Vale of Tempe. It is the epigeus of Theocritus (Id. 23) and of Dioscorides (3. 106). Both Pliny and Ovid have added their testimony to the general admiration in which this plant has been universally held. The flowers have a pleasant sweet smell, and were formerly used for medicinal purposes, particularly as an antiepileptic and anodyne. A water distilled from them had reputation as a cosmetic, but the odorous matter they contain immediately makes the flowers unattractive. The flowers are only found available in medicine, and they are frequently employed as emollient poultices, owing to the mucilaginous nature and peculiar odour which they contain. They are, however, doubtless valuable medicinal plants, whether more efficacious than poultices formed of bread or farina. Gerard prescribes the lily root internally in droplets, and for this purpose bread was made of barley meal with a little water, and eaten two or three times, for a considerable length of time. This species, as well as others, is cultivated in Siberia and eaten as the potato. The scent of the lily is exceedingly powerful, and peculiarly disagreeable to most people. It is stated that there is an instance of death ensuing from exposure to the odour of this plant.

L. bulbiferum, Bulb-bearing or Orange Lily, has linear-lanceolate scattered leaves, a bell-shaped erect corolla, glabrous and smooth, its segments are large and handsome, of a beautiful red or orange colour, pale on the outside, and without any scent. The bulb is composed of numerous thick white loosely imbricated scales. This species and L. chalcedonica is probably the epigeus of Theophrastus, 'Hist. Plant.' 6, 6, and undoubtedly the spatha-caledis of Dioscorides, 3. 127. It is a native of Italy, Austria, and North America.

L. superbum, Superb Martagon Lily, has a revolute corolla, the lower leaves whorled, the rest scattered. The leaves form a branched reflexed pyramid, and are large and handsome, and of each branch, rather divided near the tips; their smell is disagreeable. The bulb is as white as ivory. It is a native of North America, whence it was imported by Mr. Peter Collinson in the year 1738.

L. martagon, Martagon Lily, has white or purplish lanceolate leaves, pubescent scarious nodding flowers, and a reflexed perianth. Though not a native of Great Britain, it is naturalised in copes in many places.

The species enumerated are those most commonly cultivated in our gardens, each of which has many varieties and sub-varieties. They are capable of being propagated by planting the offsets of the roots and by sowing seeds to obtain new varieties. Every year the roots produce many offsets, which, however, unless greatly wanted, are better left on for two or three years. The proper time for separating them is in summer and autumn, when the winter is past and the stalks decayed. By doing this they form them firm in the ground or removing the whole and dividing the offsets from the main bulb when uncovered; they should then be planted in full sun, and three lights deep, to remain one or two years; the large roots set again in the borders singly.

The sowing of seed is chiefly practised to obtain new varieties of Martagon; it should be done in the autumn, soon after the seed is ripe, in pots or boxes of rich light sandy earth, with holes in the bottoms balf inch deep; the pots or boxes should be placed in a sheltered position during the winter and refreshed often at first with water; the plants will in two years be ready for setting out; in August they should be transplanted into nursery beds in flat drills an inch deep and three or four sunders. After having grown in this situation till the August or September following they should be again transplanted into another bed, and at greater distances; after which they may be finally removed into the pleasure-ground. The bulbs should be planted singly, as they soon increase by offsets into large bunches. All the species and varieties of Liliot are valuable as plants of ornament for the beauty of their flowers, which have a noble appearance. They are proper for the pleasure-ground and if planted with judgment, succeed each other in blooming upwards of three months. The common white lily, orange lily, and maroon lily are the finest. The orange-lily also answers well for small gardens and confined situations in towns and cities.

(Babington, Manual of Brit. Botany; Fries, Synopsis Plantarum Plur. Flora Classicæ; Rees, Encyclopaedia.)

LIMBURG, a town in the province of Liege, in the kingdom of Belgium, situated in 50° 40' N. lat. and 6° 8' E. long., on the West (Weser). It is a fortified town with two gates, on a mountain, at the foot of which is the suburb of Delhem or Dolham. This suburb is larger than the town; both together have 3000 inhabitants, who manufacture a considerable quantity of fine linen. There are marble-quarries in the neighbourhood. The railroad from Brussels to Aix-la-Chapelle passes near Limburg.

(Tissel, Handbuch: Stein, Lexicon.)

LIMBURG ON THE LAHN, situated in 50° 20' N. lat. and 6° 8' E. long., is a town in the duchy of Nassau. It is the see of a Roman Catholic bishop. It lies on the river Lahn, over which there is a stone bridge. It has a mint and four churches, of which St. George's Church is deserving of particular notice. It is near the site of the Roman vicus of earthenware, and carry on a considerable trade in the productions of the country.

(Cannacheich, Geographie; Stein, Handbuch, by Hörnemann.)

LINA/RIA (from linus, flax, owing to a similarity in the leaves), a genus of plants belonging to the natural order Scrophulariaceae. It has a 5-parted calyx, a pessamaeum spurred corolla, the lower lip 8-6 with a prominent plate closing the mouth. The capsules open by valves or teeth at the top. The species are annual or perennial plants, very rarely small shrubs, and the flowers of a beautiful appearance, racemose or spicately disposed, as the type of the genus. It is a native of Europe and Africa, and is found in chalky corn-fields in Great Britain.

L. gynandra, 4-veined toad-flax, has roundish heart-shaped leaves, 5-lobbled and glabrous; the stem is procumbent, slender, and rooting. The flowers are solitary, axillary upon long stalks, and of a pale blue colour. It is a native of Europe, chiefly on old walls. It grows abundantly in Italy and Sicily, and is found in Great Britain. There are several varieties of this species.

L. Elatine, halbert-leaved toad-flax, has ovate hastate leaves, the lower ones ovate, the peduncles glabrous, stem procumbent, and the spur straight. The flowers are solitary, on long slender peduncles, the lower lip 8-6 with the upper lip purple. It is a native of Europe and Africa, and is found in chalky corn-fields in Great Britain.

L. sparsia, spurious toad-flax, has roundish ovate entire leaves, the lower one divided, the peduncles hairy, and the stem procumbent. The appearance of this plant is similar to the last, but the flowers are larger, and the whole plant not so slender. It is native throughout Europe in corn-fields, and is found in Great Britain.

L. minor, smaller toad-flax, is distinguished by its linear lanceolate leaves, which are obtuse, glabrous, pubescent, and mostly entire. The flowers are solitary and axillary, the peduncles three times as long as the calyx, and the seeds elongate. It is found in sandy corn-fields throughout Europe and Great Britain.

L. pelosinum, is known by its racemose flowers, which are of a dark violet colour with darker venus. It is native of the south and middle of France and of Great Britain.

L. repens, is distinguished by its lanceolate sepals and angular seeds with transverse elevated lines. The stem is of a bluish colour, the stem erect, branched, and leafy. The seeds are much smaller than either of the following species. It is found on calcareous soils, particularly near the sea, in Great Britain.

L. Italica has scattered linear lanceolate leaves, lanceolate oblong sepals, and orbicular scarious seeds, with a membranous margin. The corollas are of a deep yellow colour. This species is native in the east of England and near Cork, in Ireland; it is also native of Switzerland, Italy, and Hungary.

L. vulgaris has ovate acute glabrous sepals, shorter than the capsules, and the spur. The flowers greatly resemble
those of *L. Italicus*, but are twice the size. In Worcestershire this plant is called *Butter and Eggs*. Gerard names it wild-flax, scold-flax, and that-flax. It abounds in an acrid oil which is almost empyreumatic. Taken inwardly, it induces nausea, and its power—Bishop Cotton durst neither drink nor otherwise disapprove of it. When united with milk the juice is a poison to flies.

The whole of the species of *Linaria* have an elegant appearance, and are therefore suited for garden vases. They grow well in common garden earth, but prefer a dry sandy soil. The seeds of the annual species require to be sown early in the open border where they are intended to remain. The perennial kinds may be propagated by division at the roots or by seeds.

LINDSAY, SIR DAVID, a Scottish poet, was born at Garmynot, in Haddingtonshire, about the end of the fifteenth century. He inherited from his father the estate of *The Mount*, in Fifeshire, whence, to distinguish him from many others of the same name, he is usually called Sir David Lindsay of the Mount. In the year 1512, he was appointed sur- vior, or gentleman usher, to the young prince of Scotland, afterwards James V. His duties seem to have been of the most servile kind,—he had not only to attend the person of the infant prince, and see that he was properly attended to, but to seem to have himself exercised the craft of nursing. He says—

> When thou was young, I bade thee in my arm And held thee in my hands that hope might spring; And in thy bed didst thou fast all night; With late in hand eye softly to thee sang; And often morning to thee I sang, In tenderly I flang; And sometimes playing on the floor, And sometimes on my back I sang."

There is little doubt that his genius and good-humour must have made him a very animated and delightful companion to his charge. He seems never to have been entrusted with the education of the prince, which was placed in the hands of a more suitable person—Bishop Gavin Dunbar. Neither can his Lindsay's name be connected with a curious and poetical incident. He is the author on which his kinsman, Lindsay of Pitscottie, in his *Chronicles of Scotland*, describes a spectral apparition which, in 1518, appeared to James IV. in the church of Linlithgow, and warned him against that campaign which terminated so fatally in the battle of Flodden. Sir David professed to have seen the apparition approach and vanish, and described him as *a man clad in a blue gown, belted about him with a roll of linen cloth, a pair of bootkins on his feet to the great of his legs, with all other clothes covered therewith,*

The *Dreme*, supposed to be the earliest of his writings, appeared in 1528; it is a satire on the times, representing a vision of the punishment of the prevailing iniquities in the other world. The principal persons are *Comyn* and the *Papigow*; *Complaint of John the Commonweal*; *History of Squyer Meldrum*; *The Monarch*; and *The Play, or Satire, on the Three Estates*. There is little sentiment or pathos in Lindsay's style. He* particularly avoids a tone of sarcasm, which is his principal quality. All that was powerful in the country came under his lash; and it is one of the most inexplicable circumstances in literary history that he should not have been the victim of his audacity. He particularly assails the attacks on the priesthood and the corruptions of the court; and after the Reformation his name was long popular as that of a Protestant champion. *The Satire on the Three Estates* was expressly written during the Maida drunkard of the latter part of the sixteenth century. It was sometimes acted in the open air, and could not have failed strongly to excite popular feeling against the corruptions, civil and eccle- siastical, which had become so prevalent. It *was an unanswerable proof,* says Sir Walter Scott, *of the liberty allowed to such representations at the period, that James V. and his queen repeatedly witnessed a piece in which the corruptions of the *ex* had been so truthfully and touching described.* Another feature that makes the circumstance of Lindsay's performances having such an audience, seem strange at the present day, is their broad indecency. It is certainly believed that the performances of the 17th century were of a more moral nature. Baring-Gould says, as he was long called in Scotland, seems to have had an innate liking for what was impure. His *Squyer Meldrum* is a sort of chivalric history of adventures, some of which exhibit a very loose and dangerous morality. Lindsay held the office of Lord Lyon King at Arms. In 1537 he had the task of preparing some masques or pageants to celebrate the arrival of Mary of Guise, queen of James V. The time of his death is not known, but he is said to have been alive in 1567.

(Lord Lindsay, *Lives of the Lindsay*; Irving, *Lives of Scottish Poets*.)

LINDSEY, REV. THEOPHILUS, was the youngest son, by a second marriage, of a respectable merchant and pro- prietor of salt-works at Midshires, near Middlewich, where he was born June 20, 1723, Old Style. His mother having some connection with the family, by whom she was much respected, Theophilus, Earl of Huntington, husband of Selina, Countess of Huntingdon, adopted him, and gave him his baptismal name. Lindsey entered St. John's College, Cambridge, in 1741; and, after taking his degrees, he was elected fellow in 1747, about which time, in his twenty-third year, he commenced his clerical duties at an episcopal chapel in Spital Square, London. He then became domestic chaplain to Algernon, Duke of Somerset, and after his death, travelled for two years on the continent with his son, subsequently Duke of Northumberland. On his return, about 1756, he was presented to the living of Kirby Wiske, in the North Riding of Yorkshire; and in 1758 he removed to that of Piddington, in Northampton. In 1769 he married a step-daughter of his intimate friend Archbishop Blackburne, and in 1763, chiefly for the sake of enjoying his society, and that of other friends in Yorkshire, he exchanged the living of Piddington for one at Catterick, which was nearer to his residence.

Before this removal Lindsey, who had felt some scruples respecting subscription to the thirty-nine articles even while at Cambridge, began to entertain serious doubts concerning the Trinitarian dogmatical views of the Church of England. Though, for reasons explained at some length by his principal biographer, on his own authority, he did not deem these a sufficient obstacle to the renewal of his asent to them on en- tering a new living. In 1790 his anti-Trinitarian opinions received additional strength from the commencement of an intimacy with the Rev. William Turner, a presbyterian minister at Wakefield, and Dr. Priestley, then a dissenting minister at Leeds, both of whom had been entered upon himself. While contemplating the duty of resigning his living, Lindsey was induced to defer that step by an attempt which was made in 1771, by several clergymen and gentlemen of the learned professions, to obtain relief from parliament in the matter of subscription to the thirty-nine articles, and in which he joined heartily, travelling upwards of two thousand miles in the winter of that year to obtain signatures to the petition which was prepared. The petition was presented to the House of Commons on the 5th of February, 1772, with nearly two hundred and fifty signatures, among which were those of many eminently pious and learned men; but, after a spirited debate, its reception was negatived by 271 votes to 23. Being induced to apply for a representation to parliament in the next session, Lindsey still deferred his resignation; but when the intention was abandoned he began to prepare for that important step, which involved not only severe personal sacrifice, but a separation from many esteemed friends. Strengthening his mind for the trial by the example of the two thousand ejected ministers known as the Bartholomew divines, he drew up, in July, 1773, a copious and learned *Apology* for the step he was about to take, which was subsequently published. In the following December, notwithstanding the attempts of his diocess and others to dissuade him from the step, he formally resigned his connection with the Established Church, and, selling the greatest part of his library to meet his pecuniary exigencies, he proceeded to London. He and his wife reached Exeter early in the 1st January, 1774, and they were soon reduced to so strait a state as to be compelled to sell his books, *which* were purchased at an auction by *M. Bayezid* in Essex Street, Strand, which, by the help of friends, he had been enabled to convert into a temporary chapel. His desire being to devote as little as possible from the mode of worship which he adopted in the old church, he was slightly altered from that modification of the national church- services which had been previously published by Dr. Samuel Clarke; which modified liturgy, as well as his opening sermon, *Lords, Strand, in 1774, Lindsey published a Letter to the ..."
for the maintenance of Unitarian worship. His published 'Apology' having been attacked in print by Mr. Burgh, an Irish M.P., by Mr. Bingham, and by Mr. Randolph, Lindsey published an Answer in 1776, in which he answered these writers. In 1781 he published 'The Catechist, or an Inquiry into the Doctrine of the Scriptures concerning the only True God, and object of Religious Worship,' in 1783, 'An Historical Account of the Union of the State of the United Doctrine and Worship from the Reformation to our own times; with some account of the obstructions it has met with at different periods;' an elaborate work, which had been several years in preparation.

He commenced his biographical examination of Mr. Robinson of Cambridge's 'Plea for the Divinity of our Lord Jesus Christ, by a late member of the University.' The work to which this reply had appeared several years before, but Lindsey, who disliked personal controversy, had not intended to anwer it, though his friends at length prevailed on him to do so. In 1788 he published 'Vindiciae Fidei Italiana,' a defence of his friend Dr. Priestley, in the form of an address to the students of Oxford and Cambridge; and this was followed in 1790 by a 'Second Address to the Students of Oxford and Cambridge, relating to Jesus Christ, and the origin of the great errors concerning him.' In 1792 he invited Dr. Dimey, who then left the Established Church on the same grounds as he had done himself, to become his colleague in the ministry at Exon Street, and in 1793, on account of age and growing infirmities, he resigned the pastorate. He died in his hands, publishing on that occasion a paper well discoursed (which he felt himself unable to preach), and a revised edition, being the fourth, of his liturgy. He nevertheless continued to reside at the chapel-house, as did his works. In 1795, he republished, with an original preface, the 'Letters to a Philosophical Unbeliever,' which Dr. Priestley had recently published in America in reply to Painle's 'Age of Reason;' and in 1800 he republished in like manner Priestley's works, with the knowledge of which he had not been acquainted.

The work was published in 1803, entitled 'Conversations on the Divine Government; showing that everything is from God, and for good.' The work was published on the first day of his eighty-sixth year, and was buried at Bunhill-fields. Copious biographical notices of Lindsey were published in the 'Monthly Repository' and 'Monthly Magazine' of December, 1803, the former being by Mrs. Catherine Cappe, with whom he had lived on intimate terms when in Yorkshire, and the latter by Mr. Joyce; and in 1812 the Rev. Thomas Belsham published a thick octavo volume of 'Memoirs,' in which he gives a full analysis of his works, and extracts from his correspondence, together with a list of his publications, which embraces, besides those above mentioned, several single sermons which were printed in very large numbers, and two volumes of his sermons were published shortly after his death. Another biographical 'Memoirs' of Mrs. Cappe, published in 1822, also contain many notices of Lindsey. A portrait of him accompanies Belsham's "Memoirs."
his former master Masolino into the picture of the 'Conce- 
conration,' which may have been done from memory or from some 
extisting portrait, for Masolino was certainly dead before 
Fra Filippo could see it. 
Fra Filippo is said to have been poisoned by the relations of 
Lucrezia Butti; Lanzi speaks of the fact as certain, but 
Vasari merely alludes to it as a vague report, which is the 
most the time of his life. 
It probably did her little service by poisoning Filippo, whom she evidently 
loved, for she would not return to her relations; and fifty-
sev'een years is no s very sho: life for a man notoriously given 
to pleasure; his death took place eleven years after the abduction of Lucrezia, for Filippo was ten 
years old when his father died. 
Fra Filippo was buried at Spoleto, in the cathedral, which he was engaged in painting 
at the time of his death. The son was instructed in painting by 
Filippo's pupil and assistant Fra Diamante. He after-
wards erected a marble monument, with a Latin inscription 
by Politian, to his father in the cathedral of Spoleto, by the 
order and at the expense of Lorenzo de' Medici. 
Fra Filippo excelled in invention, in drawing, in colouring, 
and in chiaroscuro, and for his time was certainly a painter 
of extraordinary merit; he must, even without reference to 
time, be accounted among the greatest of the Italian 
painters from Masaccio to Raphael, both inclusive. Some 
of his easel pictures in oil are finished with extreme care 
and great certainty, there are few in the history of the Florentine 
Academy, of which the Coronation of the Virgin, formerly in 
the church of Sant' Ambrogio, is an admirable work. There 
are some chalk studies of hands by Filippo in the British 
Museum. 
Several of his works have been engraved by 
Lasinio. 
Filippino, though not equal to his father in the higher 
quallities, surpassed him in others, especially in general 
accessories, which he was perhaps the first to bestow great atten-
tion upon, and he had much more taste than most of his con-
temporaries; he understood better the rendering of mere 
appearance, one of the most essential, though not one of the 
highest qualities in pictorial art. 
He excelled in painting Madonnas; but his chief works are the frescoes of the 
Frari Chapel, in Santa Maria Novella, and of the Brancacci Chapel 
of the Carmine, where, besides others, he painted Peter and 
Paul before the Procommus, which was long attributed to 
Masaccio, as in the 'Etruria Pittore,' where it is engraved, 
and in many other works. 
Vasari, Vita de' Pittori, &c.; and the notes to the German 
Translation by Schor; Baldini, Delle Pitture di Fra 
Filippo Lippi nel Coro della Cattedrale di Prato, &c.; Bal-
dinece, Notizie dei Professori del Disegno, &c.; Rumohr,

Carteggio Vincenzo Camillo d'Arriani, and Kastanbichl, 
Liquiddity is that condition of a material substance 
in which the particles have a perfect freedom of motion, 
without any sensible tendency to approach or to recede from one 
another, except by the action of some external power. 
Liquidity is therefore comprehended in the condition 
of fluidity, the latter term being applied as well to gases, 
and even to the principle of electricity, magnetism, &c., as to 
water, oil, &c., which are properly called liquids. (Fliiuin, 
Fluiditt, P. C.) 
The phenomena of capillary or molecular action show that 
the attractions which constitute what are called the affinities 
of substances extend to very small distances only from the par-
ticles; and hence, when the particles of a substance are situated 
beyond the limits of such attractive forces, the repellive power, 
arising probably from the action of caloric, causes the particles 
to repel each other, and to be scattered into a state of 
aciform fluidity. Now the phenomena of crystallization seem 
to indicate that the attraction of affinity is exerted with greater 
or less intensity according as the like or unlike sides of the par-
ticle are nearer together, or more remote from each other, in 
their mutual approaches; but it is probable that this modific-
tion of the attraction of affinity extends to lesser distances 
from the centres of gravity of the particles than the general attrac-
tions between them; and it may be inferred that whenever the one 
another in their mutual approaches; but it is probable that this modific-
tion of the attraction of affinity extends to lesser distances 
from the centres of gravity of the particles than the general attrac-
tions between them; and it may be inferred that whenever the one 
another in their mutual approaches; but it is probable that this modific-
tion of the attraction of affinity extends to lesser distances 
from the centres of gravity of the particles than the general attrac-
tions between them; and it may be inferred that whenever the one 
another in their mutual approaches; but it is probable that this modific-
tion of the attraction of affinity extends to lesser distances 
from the centres of gravity of the particles than the general attrac-
tions between them; and it may be inferred that whenever the one
plates. A direct downward pressure, such as is used in typo-
printing, would not produce all the required effects: the action
necessary being rather a kind of rolling than a direct pressure.
In this plate, the last in and the paper of a
passing between two rollers, the apparatus of which has an
elasticity or softness given to it by layers of padding or felt;
and the degree of closeness between the rollers is regulated
according to the strength or thickness of the impression re-
quired.
In the lithographic process, the pressure is accomplished by a
sort of scraping movement. Soon after the adoption of this
brass plate, the general practice was to use a wooden
broad table for holding the stone, covered with a tympanum
or stretched parchment; the engraved stone was inked by
rollers, the paper was laid down on it, the tympanum was
brokendown or rolled up, and the stone was pressed
firmly on the tympanum; the stone, by the action of the
levers, was made to traverse from side to side beneath this
bar, so that every part of it in turn experienced the pressure
of the bar.
All the parts of the apparatus have since undergone improve-
ment and modification. Messrs. Taylor and Martin'se lithographic press has a cast-iron upright rising from the
bed or table; and there is a carriage for containing the stone,
which carriage is supported on rollers moving along a mini-
ture railway. The scraper or bar, instead of being pressed
down by leverage, is governed by a spring, which keeps it
close to the tympanum. The tympanum, or cylinder, worked
by a handle, sets the carriage in motion, and the stone is thus
brought in all its parts under the action of the scraper or pressing-bar. The different parts of the apparatus are ad-
justed to different requirements of the art by regulating
screws.
Other machinists have improved the press in various ways;
but the general principle of the apparatus may be inferred from
these few details.
LITHORNIS. A fossil bird from the Isle of Sheppey is
duly named by Owen.
LITHOSPERNUM (from Latin, a stone, and sperma; seed;
into Latin, to the hard seeds or nuts), a genus of plants be-
ing to the natural order Boraginaceae. It has a deeply cut
calyx in five segments, a funnel-shaped corolla, with a nated
or minutely five-keeled throat. These segments are very short;
the stamens included in the tube. The nuts are smooth or
tubercular, stony, and attached by their truncate flat base
to the bottom of the calyx.
L. officinalis, Grasswell, has an erect much-branched stem,
 lanceolate acute valved leaves with tuberces and adpressed
briatles above, hairy beneath; the throat of the corolla has
minute scales within, and is of a pale yellow or greenish
colour, with whitish, minute, very hard, minute or three ripening in each calyx. They were esteemed in antient times as an infallible litholithic; their virtues in this
respect are, however, entirely imaginary. This species is native of the Tyrol, the Alps, and North America. It is found
in dry and stony places in Great Britain, but sparingly.
L. purpureo-cerulites has herbaceous stems, the barren
ones prostrate and creeping; the others erect. The leaves are
lanceolat, acute, scarious, of a dark green, with revolute
margins. The flowers are showy and large, at first red, and
afterwards of a bright blue. The nats are white, highly po-
lished, and hispid. This species has no scale in the throat
of the corolla, but merely five longitudinal downy folds. It
is native of middle and south Europe, of the Caucasus in woody
mountain places, and of England and Wales in chalky soil.
L. arvensis, Bastard Alkanet, has an erect branched stem,
lanceolate acute, hairy, and subscissil; the calyx a
little shorter than the corolla; the nuts tubercular, wrinkled,
polished, and of a pale brown. The throat of the corolla is
developed into scales, as in the former species. The flowers are
white, very small; the root of a bright red, communicating its
colour to paper. It is native of Europe, Asia, Africa, and
some parts of North America, and is found plentifully in the
corn fields of Great Britain.
L. Turbinat is herbaceous procumbent stems, lanceolate
oblong leaves, hairy calyx a little shorter than the tube of
the corolla. The upper leaves are half-clasping the lower ones
on petioles. The flowers sessile in simple or conjunctive leafy
spikes, purplish, sometimes blue, generatling into a white head.
It is native of Spain, South of France, Italy, and Hungary,
in sandy sterile places.
L. tetramorium has an herbaceous erect branched stem,
lanceolate obtuse hairy scarios leaves, the lower ones oppo-
site; the calyx is shorter than the tube of the corolla, con-
fining when bearing fruit. It is native of Egypt and the
island of Cyprus, and has the habit of L. arvensis, but is much
deriger.
L. LIVERWORTS, or LICHENS, a family of plants be-
ing to the class Cryptogamia, of which a definition is given under that title prefixed to P. C. F. The order consists of between fifty and sixty genera, of which the tympanums are divided into four
sub-orders—Hymenothriptic, Gasterothriptic, Isidiophric, and
Coniolothic: to these some systematists add Bysseaceae.
L. saxicola, (D. S.) These are again subdivided into
several tribes, each tribe comprising several genera.
The tribe Usneaeeae are characterised by having an open
disk, and being destitute of a hypothallus. It embraces the
genera Usnea, Everina, Roccella, Remonia, and Cetraria.
Several species of Usnea are known by the common names of
Jupiter's beard, Tree-beard, &c., on account of their hair-
like appearance. They are amongst the most common of the
Lichens which cover the trunks of aged trees, and give to
them a picturesque appearance. Usnea plicata is a common
species on old trees, park palings, &c, and has been recom-
manded as a remedy in hooping-cough.

The species of the genus Everina are common in Great
Britain. One of them, E. procunaria, has a peculiar power of
imbibing in perfumed cadavers and sweet
pots. It has been recommended as a remedy in pulmonary
affections. It is frequently found on the oak and other trees.
Evelyn says of it, 'This very moss of the oak that is white
composes the choicest cypress-powder, which is esteemed
a good for the head; &c.' It is similarly used by some
physicists under that name, as they do the fungi for the true
garlic (excellent for humours and fluxes), to the great
scandal of physic. It is said that E. pulmonacea is poisonous
and has a bitter taste, hence its name, but little is known of its real
properties.

The genus Remonia is found associated with the last
on the trunks and branches of trees, especially of the fir,
and the birch, as well as of the larch, pine, and the hardwod.
L. parietaria, Tree-beard, &c., promises in that intention to rival the famous Lichen
roccella or argol which is brought from the Canary Islands.'
For the properties and uses of the species of Roccella and
Cetraria see ORCHIL, P. C., and CETRAVIA, P. C. S.

The tribe Parmeliaeae is characterised by a horizontal
thallus. To it belong the genera Polypiera, Sicta, Borreria,
Remolca, &c.

Two of the species of Polypiera, P. canina and P. ephelocora,
have been used in medicine; the former as a remedy in
hydrophobia; the latter is boiled in milk and administered in
the third degree.

The species of Parmelia are exceedingly numerous; one
of the most common throughout Europe is the P. parietaria,
yellow moss. The thallus and shields are both of a yellow
colour; and Lightfoot says, 'It is affirmed to do a good yellow
or orange colour if mixed with alum.' It has also a very
bitter taste, which has caused it to be used as a tonic in medi-
cine, and it has been recommended as a remedy in intermittent
fevers, and for dropsy and the gout.

The genus Cetraria is a species of the genus Cetrella,
affords the substance known as Litmus, or Laeum. [LITMUS,
P. C. F.]

One of the species of the genus Sicta, S. pulmonacea,
has been used as a substitute for the Iceland moss. [CERTRANIA,
P. C. S.) It is used in Siberia for giving a bitter flavour to beer. It is a native of Great Britain, and is found on the trunks of large trees in England, as well as in some other parts, and almost entirely covering them with its large shaggy fronds.

A species of Borera (Borera, P. C. S.), B. furfuracea, is reputed to be astrigent and febrifuge. It is found on the trunks of large trees in England, and is used for the treatment of many complaints.

The tribe Lodiculae includes the important genus Cladonia (Cladonia, P. C. S.), and also Coscinopora and Scyphophora, which are often found on the ground forming various species of Lichens to the distinguishing not only between the bark of different species of Cladonia, etc., but also between good and bad barks of the same species.

The tribe Sphaerophorae contains the genera Sphaerophora, Fuscaria, and Indiwm. They are exceedingly elegant group of Lichens, but the species have not been much used for ornamental purposes. Indiwm cardulium is said to be rich in colouring matter.

The genus Endocarpum and Porium belong to the tribe Endocarpae. The species of the former genus are found on rocks and stones, whilst those of the latter are interesting as forming distinguishing marks between various kinds of barks used in medicine. For, in his 'Méthodes Léthographiques,' one of the first gentlemen at the court of France, he has given a description of Lichens to the distinguishing not only between the bark of different species of Cladonia, etc., but also between good and bad barks of the same species.

The tribe Vertericis is Vertericia, of which the species are very numerous. [Vertericia, P. C.]

The tribe Graphopoeis is remarkable for the forms which occur in the skeleton of the letters of Eastern alphabets. This will be seen in Oephegara scripta, in Fig. 7 of the woodcuts illustrating the article Lichnus, P. C. As an indication of the value of the Lichens in distinguishing the various species of Cladonia bark, For states that the Graphia interrupta is only found on the bark of Cladonia lycophylla. Although the study of the Lichens on the official barks has not produced all the advantages anticipated by the botanical parties, there can be no doubt of its value in many cases. Referring to this subject, Burnett observes, 'Until the publication of For's memoir on the Cryptogamic epiphytes of the official barks, the study of the Oephegara and its allies seemed to be one rather of speculative amusement than of practical utility. But now the case is wholly changed, since in these graphic plants, these living letters, written by Nature's hand, are shown to constitute inscriptions legible by men. A diligent and curious eye, in projecting from the natural surface of the tree, the letters of an ancient or modern inscription, would be able, without any great expenditure of labour, to detect the characters of the ancient inscriptions, and so forth.

But, like the hieroglyphics of the Egyptian engravings, their meaning was buried in obscurity, and so little guessed at, that it often was doubted whether they had any meaning at all, or were nothing but the mere productions of the senseless forest. But, when the sight of a person familiar with the ancient language may detect the inscriptions of the vegetable world, and be of a natural Rosetta-stone deciphered these hitherto unknown manuscripts, and taught us to perceive this part of the sacred Scriptures of creation.'

But, like the hieroglyphics of the Egyptian engravings, their meaning was buried in obscurity, and so little guessed at, that it often was doubted whether they had any meaning at all, or were nothing but the mere productions of the senseless forest. The study of these inscriptions, it may be said, is a subject of inquiry, which may be compared to the discovery of the Chinese language, and the deciphering of the ancient Chinese inscriptions, by a person familiar with the ancient language may detect the inscriptions of the vegetable world, and be of a natural Rosetta-stone deciphered these hitherto unknown manuscripts, and taught us to perceive this part of the sacred Scriptures of creation. (Burnett, Outlines of Botany; Lindley, Natural System; Lindley, Floris Medicola; Elies, Lichinographia Europea reformata.)

LIVELYMEN OF LONDON. [London, P. C.]

LOCK, a kind of secret fastening in which a movable piece, termed a bolt, may be projected by the action of a separate instrument, called a key, introduced into the lock in such a manner as to lay a hindrance to the natural motion, so as to release the door, cover, or other article to which the lock is applied, excepting by another application of the key. While, however, the above appears to be the distinct definition of a lock, there are many locks in which the bolt is projected by the action of a spring, without the aid of the key, and in which it may be drawn back upon one side of the door to which it is applied by the action of the spring, without being moved from the other side without the application of the key. Many such locks fall under the general denomination of latches or latch-locks. In other locks, again, there are two or more bolts, one of which only can be removed under the control of the other being moved by handles; while in another class of locks two or more bolts are shot or project by the action of the key alone. In addition to such differences, the varieties in the form and size of locks, and in the arrangement of the parts, are almost infinite. In the kinds of lock in which the bolt is not under any circumstances projected beyond the casing of the lock, but is caused to shoot into or through a staple which drops into the lock to receive it. In deck-locks and some others the bolts project permanently, and are of iron, or of brass, of a hooked shape, adapted to catch, by a slight movement, into cavities or staples provided to receive them. Padlocks are a kind of detached lock in which a curved bar of iron, pivoted upon the lock at one end, may be passed through a staple, and then so secured by shooting the bolt into a cavity in its free end, which is inserted into the lock for the purpose, that it cannot be removed from the staples or links through which it has been passed.

By far the greatest part of the almost innumerable ingenious contrivances for rendering locks inviolable may be classed under one of two systems of security, the distinction between which was pointed out by Mr. Ainger in a paper read before the Royal Institution in 1827 (an abstract of which was published in the first volume of the Quarterly Journal of Literature, Science, and Art), and is further illustrated by the following statement: "The keys of a lock are closely connected by the literature of the Encyclopaedia Britannica. Of these means of security, the first consists in the insertion in the lock of fixed obstacles, commonly called wards, which prevent the entrance or revulsion of any instrument or key which may be used in opening the lock with corresponding openings, so as to thread its way among them, and thus render the bolt inaccessible to any but the proper instrument; while the second consists in the use of moveable impediments, which in their most general form are called tumblers (a term which, for convenience, we may apply generally), to the motion of the bolt itself, the security arising from the difficulty of bringing these moveable impediments, by the use of any but the proper key, to the actual and relative positions necessary to allow free motion to the bolt. In many locks both of the above means of security are used, but for convenience we shall here notice the peculiarities of each system independently of the other. In dealing with the first system we may include under one general head all contrivances whatever by which the approach of the key to that part of the bolt by which it is capable of being shot backwards and forwards is impeded.

The key of an ordinary lock consists of a cylindrical shank with a loop-shaped handle at one end, and a piece called the head at the other end. The key is inserted into the lock by projecting from the shank, and is turned round between the thumb and fingers, so that the bit end of the key may be seen in contact with a part of the bolt which is so shaped that the bit of the key cannot pass it, to complete its revolution, without a spring or other means, until it is again moved by the reverse action of the key.

The first and simplest means by which the entrance of a false key may be rendered difficult, is by giving a peculiar form to the substance of the bit, and either adapting the form of the key-hole exactly to it, or inserting pieces of metal in the lock in such a way as to prevent the admission of a bit of different shape. Fig. 1 represents several varieties of key-hole. (See Fig. 1.)
of the two could be employed to open the other's lock, the first having two pins or simple wards, the second two L-wards, and a third a T-ward between two plain wards; but while these afford security against ordinary keys, they afford no whatever against a pack or skeleton key like L, Fig. 3, which opens both other locks. This skeleton key is guarded merely by wards attached to the back-plate; the only part essential to the moving of the bolt being the extremity of the bit, which is retained in the skeleton key with nothing but a slender piece to connect it with the pin or tumbler. The security may be greatly increased by the use of other wards, attached to the opposite plate of the lock, and requiring notches in that part of the bit of the key which is represented by the slender connecting piece in the skeleton L. Such is the case in all the keys represented in Figs. 4, 5, and 6. In Fig. 4, L represents a key for a solid-warded lock, which might, however, be easily picked by a skeleton key resembling r, Fig. 6. The greater complication of the wards in m, Fig. 4, increases the difficulty of picking; while by the adoption of the arrangement shown at n, Fig. 4, the difficulty of introducing a false key is made perhaps as great as possible, since no instrument that does not thread all the intricacies of the wards could answer the purpose. This form, however, requires very accurate workmanship, and unavoidably weakens the key to such an extent that it is in danger of breaking in the lock. All the keys hitherto represented, as well as those in Fig. 6, are pipe-keys, adapted for such locks as have a fixed pin or axis, and can only be opened from one side. It is, therefore, of no consequence that the wards attached to the back and front plates of the lock should resemble each other. In ordinary door-locks, however, in which the key may have to be inserted from either side, it is essential that the wards attached to the two plates, if such be used, should either be precisely similar, or should bear such a relation to each other that notches may be cut in both sides, or rather edges of the bit, or, as it is sometimes called, the seat, of the key to suit both sets of wards, it being a necessary condition that the two sides of the bit, marked a and b in the cut, Fig. 5, should be perfectly alike. In such locks there is a very common form of an intermediate plate, which enters the opening marked c in the annexed figure, and which carries, on one or both of its sides, the principal wards; and in many cases the bit of a key divided by such an opening may be considered as constituting a double key, of which only one-half is used at one time, that half being either a or b according to the side through which the key is put into the lock. Such is the key in the form from which Fig. 5 is drawn; although, as it is the key of a tumbler lock, both halves are brought into use at once, whatever may be the direction in which the key is applied, with this difference, that when the key is applied from the outer side of the door the part marked a moves the tumbler and b the bolt, while when the key is put into the lock from the inner side a moves the bolt and b the tumbler. The remaining illustrations of warded keys are intended to explain the theory of *master-keys*, which was early understood by the ingenious locksmiths of Wolverhampton. In Fig. 6 the wards of the keys o, p, and q are so far different from each other that neither of those three keys would open the lock designed for either of the other two, but a key formed like r would readily open any of the locks of the other three, or any other of a more extensive series, or suit, of locks constructed on the same principle. One defect of the principle of security by wards is that, however complicated they may be, an ingenious pickers will mostly be able to detect their form and position, by inserting a blank key with the bit covered with wax or tallow, so as to receive an impression of the concealed obstructions in the lock. It is well to observe that it is a very common practice to cut more notches in the key than are wards in the lock, so that the complex appearance of a key is no certain
proof of the secure construction of the lock to which it belongs. Indeed some of the commonest locks are manufactured without any wards at all, although the keys are invariably made as if wards were employed.

As above stated, some contrivance is necessary to keep the bolt steadily in the position in which it is left by the key; and in locks which depend upon wards for their security, this is usually effected by means of a spring, as illustrated by Fig. 7, which represents the interior of a small cupboard lock, with the bolt, a, b, half shot, or in a position intermediate between locking and unlocking, which, in the moving either backwards or forwards by the action of the bit of the key at c in a curved hollow formed in the lower edge of the bolt. The end a of the bolt is divided into two parts, shooting through separate holes in the rim of the lock; the top of the bolt carries a long elastic piece formed by nearly separating a stout lamina of metal from the body of the bolt, and giving it an inclination to diverge from the bolt at the end b; and the lower edge of the bolt, behind the curved part acted upon by the key, is indented with two deep notches, b and d, with a smooth convexity between them. The opening in the back rim of the lock through which the end b of the bolt passes, is so small as to compress the spring with considerable force. If, therefore, the key be so applied as to shoot the bolt forward, the re-action of the spring will cause the notch b to hold firmly on the edge of the rim, from which it cannot be disengaged without releasing the bolt and compressing the spring, so as to allow the convexity between b and d to pass over the edge of the rim, after which the notch d will hold on the rim in like manner. The necessary raising of the bolt and compression of the spring is properly effected by the action of the key, but as it may be effected by pressure upon the end of the bolt, the security of locks in which such an arrangement is adopted, which are called back-spring locks, is inferior to that of locks, wherein the second lever of our subject, in the means of retaining the bolt in its position, as well as from the defects already explained as incident to the use of wards.

We pass naturally from the consideration of the back-spring as an essential feature in a lock protected by wards alone, to the explanation of one of the most important principles of applying or second principle of security, that which consists in the use of moveable impediments to the motion of the bolt, and which may be applied, as an additional security, to locks in which the most ingenious arrangements of wards is employed to prevent the access of a false key to the bolt. Fig. 8 represents, side by side with our figure of a back-spring lock, a similar lock provided with a common tumbler. In this figure the bolt a, b, though shot backwards and forwards in the same manner as that of Fig. 7, has no spring, or notches to catch on the back rim of the lock, to hold it in any required position; but it is provided with two notches in its upper edge, at e and f. Behind the bolt is a piece of metal called the tumbler, pivoted to the plate of the lock at f, and continually forced downwards by a spring which presses upon its upper edge. The upper part of the tumbler is, like the bolt, divided into two parts, the front part, to which the bolt is distinguished in the cutting by being covered with a light tint, while the shape of the lower part, which is concealed by the bolt, is indicated by dotted lines. At the angle e the tumbler is divided into two parts, the front part, to which the further turning of the key shoots it back, when the stud of the tumbler falls into the notch c, and again secures the bolt. It is obvious that so long as the tumbler remains in its proper notch, the bolt cannot be moved backwards or forwards by any pressure upon its ends; and also that the lock cannot be opened by any pick or false key unless its bit be so formed as to reach the tumbler as well as the bolt. To render this more difficult, the tumbler is often made a little lower than the bolt, so as to be acted upon by a step formed on the bit of the key; while further complication and security may be obtained by the use of two or more tumblers, which may be acted upon by different parts of the key. It is evident that the necessity requisite in the length of the bit forms a strong recommendation of even the commonest tumbler locks; for if the bit be ever so little too short it will not lift the tumbler out of its notch, but carry it little too long, it will not enter the curved portion of the bolt.

According to Mr. Ainger, the principle of security by tumblers, though of comparatively modern application in this country, has been known to the Egyptians from a very remote period. In the lock now commonly used in Egypt and Turkey, the bolt is secured by a number of pins, which, though contained in other times in holes or sockets in a solid piece through which the bolt slides, fall into holes in the bolt when it is shot. This contrivance is illustrated by the annexed diagram, Fig. 9, in which a is a part of the bolt, capable of sliding through a piece b, in which are a number of hollows, c, c, c, each containing a movable pin. As it is only by a sectional diagram that these pins can be represented, they are drawn as if all were in one straight line, which, however, is not the case in practice. In the present position of the bolt the pins rest upon its upper surface, and offer no impediment to its motion; but if the bolt be slid forward until the holes d, d, d, come under the pins c, c, c, the lower ends of the pins will drop into them, and the bolt will consequently be held fast. It can only be released by the application of a kind of key which has a series of fixed pins exactly corresponding with the holes in the bolt, and which, being introduced into the bolt by the hollow or cavity e, is pressed upwards in such a way as to lift the pins clear of the bolt. The security arises from the concealment of the obstacles to the motion of the bolt, and from the circumstance that, supposed to a person to obtain a correct impression of the holes, it would be difficult to ascertain the exact length necessary for the pins of the key. If too short they would not raise the pins clear of the bolt; and if too long they would enter the holes in the solid part above the bolt, and so impede its motion. This kind of lock, Mr. Ainger observes in the 'Encyclopædia Britannica,' appears to be extensively, or rather universally, employed for gates, doors, or houses, as well as for the smallest articles of furniture. The evidence of its alleged antiquity is derived," he adds, according to M. Denon (in whose magnificent work on Egypt it was published), from the circumstance of finding one sculptured among the bas-reliefs which decorate the great temple at Karnak, from which also it was ascertained that during forty centuries the lock had undergone no sensible change.'

Notwithstanding the high antiquity of the tumbler principle, its first important application in this country appears to have been made by Barron, in 1774, according to most authorities, or in 1778, according to the 'Encyclopædia Britannica.' In the simple form of the tumbler represented in Fig. 8, there is the disadvantage that, while it effectually prevents the removal of the bolt unless the tumbler be raised high enough, it presents no obstacle to its removal when, by the use of a false key, the tumbler is thrown up beyond the proper degree. This defect is remedied in Barron's lock, and in many more recent contrivances which are based upon it, by the use of several tumblers, each of which must be raised to a different degree, and any one of which, if lifted too high, will form as effectual a barrier to the motion of the bolt as if it were not lifted at all. To illustrate this, let a, Fig. 10, represent a tumbler pivoted at b, moved downwards by the action of a spring, not shown in the cut, at b,
Chubb's detector lock, the original patent for which was obtained in 1818, though an important improvement upon it was secured by a second patent in 1844, is one of the most celebrated locks made on the principle above described. Its peculiar merit consists in the addition of a lever, called the detector, which is so fixed that, while it does not affect the bolt at all under ordinary circumstances, it cannot fail so move as to drop a catch into the bolt if any one of the tumblers be lifted a little too high, as some of them must inevitably be by any attempt at picking the lock. By thus fixing the bolt immovably, it not only renders useless any further attempt at picking the lock, but also gives notice of the attempt which has been made, when the proper key is next applied. By a very ingenious contrivance the proper key is only introduced after lifting all the tumblers to the proper degree for shooting the bolt, to release the detector by a peculiar movement, and thus to restore the lock to its usual state.

In Bramah's lock, which was invented and patented about 1784, the principle of tumblers or moveable obstacles is applied in a very different manner to that above described, and the use of wards is entirely abandoned. In a kind of preparatory record which was attached to his specification, and is quoted by Holland, Bramah alludes to the insufficiency, for the purpose of security, of all contrivances of the ward, or fixed obstacle character, not only on the grounds above noticed, but also because, according to Holland's abstract of his argument, 'the variations capable of being made in the disposition of such wheels or wards, and in the form of the key's bit, are not sufficient to produce the required number of locks, without having large quantities exactly alike, and their keys capable of opening one another reciprocally; in consequence of which they become a very imperfect security against violation, as any ill-disposed person might, by furnishing himself with a number of old keys, be enabled to open almost all the common locks in the kingdom with as little difficulty as if he had in his possession the key belonging to each lock.'

In devising a remedy for these defects, Bramah contrived a method of applying moveable impediments very different to that adopted by Holland. Retaining the principle in which required, every such impediment should require its own peculiar movement, he provided for restoring them, by the application of an elastic force, to such a position should leave no trace of, and afford no possible clue to the discovery of, the extent of their motion under the pressure of the key, so that the opening of his lock without the true key is, to use his own expression, 'as difficult as it would be to determine what kind of impression had been made in any fluid, when the cause of such impression was wholly unknown; or to determine the separate magnitudes of any given number of unequal substances, without being permitted to see them; or to counterfeit the tally of a banker's cheque, without having either part in possession.'

To explain, more readily than could be done by a mere representation with the aid of words, the ingenious contrivance by which the above effect is produced, we may adopt, with some alteration, a diagram of a supposed apparatus illustrative of its principle, which is given by Holland from the original drawings attached to Bramah's specification. Let a, a, Fig. 13, represent, isomorphically, a frame in which is mounted the bar or bolt b, b, in such a manner that it is capable of longitudinal motion. In the nearer edge of this bar or bolt are cut fournotches, to receive the lower vertical sliders c, c, c, which, when they are in the position represented in the cut, serve to hold it immovable. In the
further edge of each of those sliders, however, is cut a notch of such size and depth, that if it be brought to the same level as the bar $b$, the bar will be capable of sliding through it. These notches in the sliders, shown by $1$, $5$, $9$, and $4$ in the diagram, are cut at various degrees of elevation, so that, in order to bring them all to tally with the bar at once, which is necessary to enable it to slide through them, each slider must be lifted up to a certain degree, different from the elevation of either of the others. As, however, the lower ends of these sliders, which pass through the bottom of the frame $a$, $a$, and which are the only parts of the apparatus intended to be visible, have a uniform degree of projection, it is impossible to tell how high each of them must be lifted in order to make its notch tally with the bar; and this can only be done by the application of an instrument resembling that marked $g$ in the figure, in which are a series of slits, $e$, $e$, and $f$, corresponding with, and capable of fitting on to the lower ends of the sliders $e$, $e$, and $f$, and each slit being cut to exactly such a depth that when the instrument, or key, is put upon the ends of the sliders, and pushed up until its lower end comes in contact with the bottom of the frame, its corresponding slider will be raised to the degree necessary to make its notch tally with the bar $b$. While the key, $g$, is held in this position, the bar $b$ may be slid backwards or forwards; but when the instrument is removed, and the key is withdrawn, the sliders fall, by their own weight, into the position represented in the cut, and the bar is again held fast.

In order to explain how the principle of security illustrated by the above imaginary contrivance is applied in Druamah's lock, we must premise that the ordinary mode of shocking the bolt, by the action of the bit of the key, is entirely abandoned; the office of the end of the bit being performed by a stud attached to the end of a cylindrical barrel which is mounted in the lock, and which contains all its essential parts, or, rather, all the parts essential to its security. Fig. 14 represents an elevation of a section of a street-door latch-lock, the central figure being a side view of the barrel, and the other representations of its back and front ends, respectively. In this cut $a$, in the side and back views, represents the lock; $b$ is the sliding bar, which, having been released from its own rotation, moves slowly along its axis, and is inserted, by its inner edge, in the slit or opening $b$ in the barrel, Fig. 14. The four notches in the inner edge of the plate are thus placed upon the edges of the four sliders in the barrel; and as the plate is screwed by the holes shown at its two sides, it is a moveable part of the lock. It follows that the barrel cannot be turned round unless the four sliders and its parts, in the order of their notation, may all tally with the edge of the plate, Fig. 15. Fig. 16 is a longitudinal section of the barrel with the end of the key as applied to bring the sliders into the required position for allowing the barrel to turn; and Fig. 17 represents, at $a$ in profile, and at $b$ in an end view, the key itself separately. The key, being tubular, is put upon the fixed central pin or axis, shown in Fig. 16, the four radiating notches in the end of its pipe fitting, at the same time, on to the ends of the four sliders, which are shown in Fig. 14. These sliders, two of which are shown white in the section, Fig. 16, are, in the absence of the key, kept pressed against the front of the barrel by means of a collar which slides upon the central pin or axis, and is pushed forward by a helical spring which surrounds the pin, and abuts upon the back plate of the barrel; but when the key is pushed into the lock it comes in contact with the sliding collar, compresses the spring, and thus allows each slider to be pushed forward to a degree exactly proportionate to the depth of that notch in the key which acts upon it. By this means the deepest of the three notches represented in the outer edge of each slider is brought to tally with the edge of the circular plate, which is represented as pushed in Fig. 16, and shown edgeways, at $b b$ in Fig. 16, and thus all impediment to the rotation of the barrel is removed, and consequently, by moving the key, the barrel, with its stud $a$, may be caused to revolve, and to shoot the bolt just as an ordinary key would do. When the barrel is returned to its original position, the key is withdrawn, and the action of the spring restores the sliders to their ordinary situation, in which they slide into the notches of the circular steel-plate, and keep the barrel stationary.

In order to render the above description as simple as possible, we have omitted in it several minor points which tend to the security and efficiency of the lock. The whole of the apparatus above explained is securely enclosed in a turned brass box, so that even the ends of the sliders are only visible at the farther extremity of the deep and very small key-hole, the centre of which is occupied by the end of the pin or axis, which, projecting considerably beyond the sliders, greatly increases the difficulty of bringing any false instrument to act upon them. The small bit of the key, the main use of which is to cause the lower end of the right-angled plate which forms also a stop to prevent it from being pushed too far, and to indicate when the sliders are brought to the proper position. To prevent the sliders from working too loose, or from dropping in the manner of the false key, as they do in some locks, when by the compression of the helical spring they are released from its influence, they are made of a thin piece of metal doubled, as shown at $c$, Fig. 17, so that their inner ends, having an inclination to spring open, press with sufficient force against the sides of the grooves in which they slide to keep them in whatever position the pressure of the key may place them, until such pressure is withdrawn, and they are exposed to the counter-pressure of the helical spring. The portability of the key constitutes a great advantage of this kind of lock, as a key which may always be carried in the waistcoat pocket, or even attached to a watch-chain, is less likely to be missed, or to fall into the hands of improper persons, than a large key. Again, both locks and keys, being made almost wholly by machinery, may be made with great accuracy at a moderate cost, while the production of a false key from an impression of the true key, or even from the key itself, would be an easy task to a person not possessed of the requisite machinery. The two additional small notches represented in the tumblers of Fig. 16 and 17, to which no allusion has yet been made, add greatly to the security of this kind of lock. For some time after its introduction it was deemed absolutely inviolable, but ingenuity at length overcame the difficulty of picking it. This was accomplished by what has been aptly termed the invention of the "double locked," or, as it is sometimes called, the "broken" key. The pick, being placed in the barrel in such a way as to give it an inclination to revolve on its axis, the pickers tried all the sliders in succession,
to ascertain which of them, by the inevitable inaccuracy of workmanship, pressed with most force against the circular locking-plate. This slider he then gently pressed until, by the revolution of the infinite resistance of the locking-plate, he found that its notch was in the required position, when, having secured it, he proceeded to adopt the same course with each of the other sliders in succession. Thus, by an extraordinary exertion of skill and dexterity, Mr. Russell was able, in many instances, to accomplish the apparently impossible feat of picking a Bramah lock. No sooner, however, was this fact made public, than an efficient remedy was devised by a person named Kemp, who was then in the vicinity of Bramah's establishment, by the simple device of cutting one, two, or more additional or false notches on each slider, and enlonging, as shown in Fig. 15, the inner portion of each notch in the locking-plate. The result is that it is utterly impossible for a picker to know whether he gets the true notch, or one of the false notches, on to the edge of the locking-plate, while, supposing him, against all probability, to find the right notch in a majority of the sliders, the fact of one only hanging on a false notch would be sufficient to prevent the barrel from turning, owing to the depth of such notch being insufficient to clear the plate. The enlargement of the notches in the locking-plate, which allows of a degree of motion far exceeding any which could arise from mere inaccuracy of workmanship, adds to the baffling effect of the false notches, by the use of which the Bramah lock may be fearlessly said to be rendered, so far as the risk of picking is concerned, absolutely secure from picking. The same principle of picking, and the same kind of expedient for security against it, with variations of detail which need not be noticed here, have been applied to tumblers and other ordinary locks.

The infinite variety attainable in the manufacture of locks on this principle forms one of its great recommendations. Our illustrations refer to one of its simplest forms, in which only four sliders are used, but in this form the variety attainable, without any difference in the size of the key or the diameter of the central pin, is very great. By the use, however, of five, six, or seven sliders, the number of different locks may become infinitely large; and to the ordinary user, who may adopt the system in some cases, but is not likely to adopt it in others, this perfection of security will be a great inducement to the use of the brake. If his key be required to be of a single size, or to go into a series of locks of the same kind, and he is able to increase the number of sliders, the variety of locks will be increased in almost infinitum.

Bramah himself showed that if twelve sliders were employed the number of changes which might be produced by simply varying their relative positions, would amount to 79,001,500; while by adding one more slider the number would be increased to 6,227,019,500; so that, as he observes, "one lock, consisting of thirteen of the above-mentioned levers, sliders, or other moveable parts may (by changing their places only, without any difference in motion or size), be made to require the same immense number of keys. It may be observed that in the event of a key being lost, or broken, or any other accident occurring, on account of having been altered, it is possible to change the relative positions of the sliders, so as to render the old key useless; also that master-keys may be made, if required, by constructing a suit, or combination, of each of the sliders in every possible position of the two series of notches, and then applying to each of them in succession the intended master-key, which must have notches different to any of the ordinary keys, and cutting new additional notches in the sliders to suit it. Such, indeed, is the principle upon which the notches of ordinary Bramah locks are cut, the key not being fitted to the lock, but made first, and having its notches cut by a machine which provides for a continual change in their order and depth. This done, each key is applied to a separate lock, with blank or uncut sliders, and the notches in the sliders are cut while they are thus held in the proper position for the key. By any other arrangement it would be almost impossible to secure the required accuracy. Owing to the very small size of the protecting apparatus, the Bramah lock has been applied to many ingenious purposes, including the construction of lockers, suitcases, and other kinds of lock, and which we may notice the locking of liquor-cocks. Mr. Russell's contrivance for thus applying it is referred to under Cock, P.C.S., p. 385; and we see no reason why, for small cock-pipes, this arrangement should not be adopted, in which the revolving barrel of the lock should be attached to, and indeed form the upper part of, the revolving plug of the cock itself, so that a single motion of the hand should be sufficient to wind up the lock and open it. The arrangement would have this advantage, that it would be impossible, by inadvertence, to leave the cock unlocked, since the act of turning off the liquor would both lock it and, by the force of the spring, so far eject the key that it could only be left in the lock by design. In the forty-eighth volume of the 'Transactions' of the Society of Arts (part i., p. 182) is a paper by Mr. S. Mordan, who has gained much celebrity by his manufactory of locks, on a curious application of this invention to what he calls a "lock-protector," which, in fact, a scutcheon, or shield, adapted to cover the key-hole of a room door, and barring in the key, the combinations being produced by applying this scutcheon to a key-hole on the outside of a door, and turning its key a quarter round, two lancel-shaped pieces of steel are projected from a little box at the back of the buttscrew, in such a manner as to encroach into the opposite sides of the key-hole, and to hold the scutcheon so firmly in its place that nothing short of the application of violence can remove it, until, by a fresh application of the little key, the locks are opened. The chief object of this contrivance is to enable travellers at inns to prevent their chamber doors from being opened in their absence, by closing up the key-hole.

A lock was invented by Mr. Kemp, of Cork, in 1816, in which the peculiarities of both Barron's and Bramah's locks are combined in such a way as to afford, in the inventor's opinion, greater security than can be attained by either alone. In this lock, which he calls the union lock, a number of pins or sliders, which detain the bolt much in the same way as the sliders of Bramah's lock detain the locking-plate, are acted upon by the ends of a series of tubes, of various lengths, but equal to five, six, or seven, of the number of sliders of the key. This kind of lock, its inventor justly pleads, must be far more difficult to imitate than either Barron's and Bramah's, so that it affords greater security against any attempt to break open the key in this manner. Hebert, in noticing this invention, observes, that until a complete remedy is provided against the possibility of copying or imitating keys, the art of lock-making is imperfect, and no locks are absolutely secure; and he adds that he has in his possession a lock the key of which cannot be copied—a locksmith possessing no tools by which an exactly similar one can be made. The machine by which the original one was made, he added, was so small that it could not be exhibited, producing another like it. The lock is very simple and strong, and might, he says, be manufactured cheaply; but as the inventor was waiting for an opportunity of bringing it before the public, Hebert gives no account of its construction.

As a means of security somewhat differing from any of the above, and affording certain advantages peculiar to itself, we may here notice the permutation or combination principle, of which the simplest application is in the lock known often termed a puzzle-lock, which opens without a key, but is regarded rather as an ingenious toy than as an available substitute for locks of the more usual construction. In the common lock, of which the number of different combinations from one or more of its sides, is slipped through a series of circular plates or discs, each of which is capable of being turned round upon itself as an axis. The holes or apertures for inserting the keys are situated in every plate or position of the series of discs, and are so arranged that unless the whole of them are turned round to the exact position which they occupied when the bar was slipped in, it cannot be withdrawn. To provide for bringing the rings to this position after they have been disturbed from it, the periphery of each is marked with a series of letters or numbers, a certain predetermine combination of which, which should be known only to the possessor of the lock, must be brought into a straight line by turning the several rings round with the thumb and finger. As the number of combinations which may be effected, like the number of changes in the relative positions of the tumblers of the ordinary lock, is almost infinite, while only one combination will enable a person to open the lock, a high degree of security may thus be attained. The essential defect of this arrangement is, that the secret of the lock must be known to the person who made it, and is liable to be known to persons from whom it is desirable to secure the lock. The Marquis of Worcester, in whose "Century of Inventions", 1790, a puzzle lock is described, which lay claim to the most marvellous properties, was, according to the passage, from the seventy-second article in the Century, to have devised an improvement upon this apparatus, as he refers to it in "a series of curious and ingenious locks, the locks of the properties of which he describes as being the same as the other, though a woman, may, with her delicate hand, vary the ways of coming to open the lock ten millions of times beyond the knowledge of the smith that made it, or of me who
Invented. The details of this invention are not given, but in the third volume of the 'Transactions' of the Society of Arts, 1800, is a description of an escutcheon of similar character, invented by Mr. Marshall, and rewarded by the Society in 1784, in which the escutcheon or door by which the key-hole is closed is held by a pin passing through a single circular aperture, and those used in the common letter or puzzle padlock, but with this important difference, that instead of the rings or plates being formed each of a solid piece of metal, each consists of an inner and outer ring; the inner one, which contains the notches for allowing the bar to pass through, being so mounted within the outer one, which has the letters or numbers on its periphery, that it may be turned round within it, or held fast in any required position, at pleasure. The numbers, or letters, upon which the opening depends, are fitted to the internal notches, and the external letters which serve as an index of their situation, may be varied almost indefinitely; and thus, whenever the owner suspects that the secret is known to any improper person, he can vary the combination of letters by which the opening is determined. The details of this ingenious contrivance are fully given in the volume above referred to. In the thirty-eighth volume of the 'Transactions' of the Society of Arts, pp. 111-115, is a minute account of a lock invented by Mr. Ainger, in which, in addition to other ingenious features, is an application of the principle of permutation to a key, which, without any great complication, the means of not only rendering the imitation of the key all but impossible, but also of so throwing the key itself out of order, that there would be 512 chances to one against a stranger opening the lock, as against the Holland, then...
LOG
218

security. It is a defect of ordinary draw-back locks that occasionally, from want of oil, from the bevelled end of the bolt becoming rusty, or from some other cause, they will not close without slamming the door violently, and are liable not to act at all. It may be so close as to all appearance, shut properly, without the bolt shooting into its socket. To remedy these inconveniences, Mr. Bullock devised, and submitted to the Society of Arts in 1801, a very simple addition to the ordinary door-lock, consisting of an internal catch which detains the bolt when it is drawn back, out, is released the instant the door is thoroughly closed, by the pressure of a small projecting piece of metal fixed to the inside of the lock. Details of these are fully given in the Society’s Transactions, vol. xix. pp. 290-293.

The second invention referred to is Chubb’s combination latch, which combines the simple lifting action of the ordinary French latch, or that which opens with a handle inside the door, and with a key from without, with much of the security of a tumbler lock. In it two, three, four, or more distinct latches are mounted, like a series of tumblers, upon one axis, and made to shut into or behind a double catch, in such a way that they can only be disengaged from it by being all of them raised at once to one exact height, by an arrangement similar to that by which a series of tumblers are raised.

LOCUST (the Gryllus migratorius of Linnaeus, Locusta migratoria of modern entomologists), a well-known insect, belonging to the order Orthoptera and family Locustidae. Locusts, with great strength of limb and agility, and, being gregarious, are thus enabled to commit great devastation, so that when a swarm has destroyed the vegetation of one district, they are enabled to take flight to and traverse another, and do considerable damage thereto. The migratory locust has occasionally visited England, and about the middle of the last century did some damage in many parts of our own country. In Southern Europe, the East and Northern Africa, there is not an uncommon sight of such swarms, which, swarming so vast as to destroy all vegetation, whilst the putrifying carcasses of their dead inflict the air. The Arabs and people of Nigrata use them as food. For full details of the habits, &c. of the Locusts, see Kirby and Spence, Introduction to Entomology.

LOGGE, THOMAS, is supposed to have been born about the year 1566. He was entered at Trinity College, Oxford, in 1573, took a degree, and then, going to London, became an actor and play-writer. About 1580, in an answer to Gosson’s ‘School of Abuse,’ he wrote a ‘Defence of Stage-plays,’ which was suppressed by authority, and is now one of the rarest of English books, only two copies being known. Another work of Logge, his ‘Alarum against Uaures,’ which takes up incidentally the defence of the stage, was printed in 1588. The same year he was student of Lincoln’s Inn. Afterwards, it has been conjectured, he became a soldier; and it is known that, in some capacity or other, he accompanied the expeditions of Clarke and Cavendish. According to tradition he was unusually received by the historian of our early literature, this fiery person went through yet another change; for he is usually identified with a Doctor Lodge, who took his degree in medicine at Avignon, printed in 1626 a book on the Plague, and obtained a passport from the Privy Council to ‘travel into the Archdiocese of his country,’ and recover debts owing to him. Lodge is believed to have died of the plague in 1625.

He was a voluminous and versatile writer. He translated Josephus and Seneca (‘The Works of Josephus,’ Lond. 1602, fol.; ‘Seneca’s Works, both Moral and Natural,’ Lond. 1614, fol.), he published novels, volumes of verses, and miscellaneous pamphlets; and he was a distin-
guished contributor to the drama in the years immediately preceding the appearance of Shakespeare. His extant dramatic works are two: 1, ‘The Wounds of Civil War, lively set forth in the True Tragedies of Marius and Sylla,’ 1594, 4to., reprinted in the last edition of Dodgley’s Old Plays, vol. viii.; a stately historical play, with some eloquence, much action, and little interest either of character or incident. 2, ‘A Looking Glass for London and Englande; made by Thomas Lodge, Gent, and Robert Greene, in Arthurs Magister,’ 1594, 1596, 1602, 1617, 4to.; a whimsical but animated dramatic essay, intended to close the line of Greene. But Lodge’s own exertions as a dramatist, although they en-
title his name to a place beside those of Greene and Peele, are less owing to us than the assistance which one of his works furnished to those of another. One of his novels, entitled ‘Rouslanye: Euphanes Golden Legacie; found after his death in his cell at Siloxeda. Bequested to Philantus Sonnes, nours up with their Father in England. Fetch from the Canaries; ’ 1590, 1592, 1620, 1623, 1642, &c., 4to., reprinted in Mr. Collins’s ‘Shakespeare’s Library,’ 1840. From this source come the closely the leading incidents (indeed many also of the minor ones), the grouping of the characters, and many of the strokes of portraiture, for his ‘As You Like It.’ While a perusal of the novel cannot diminish our admiration of the play, it is yet an ample duty.

In the midst of that which is unskilful, somewhat that is dull, and a good deal in the bad taste of Lyly’s Euphanes, his novel, the novel, though written by the man who, and in many pieces finely poetical, both in its prose descriptions and narrat-
vive, and in the interspersed verses,

LOGGINGS, THE LAW OF, differs according to the custom which regulates each particular case from the general rules of law between landlord and tenant. (Tenancy and Landlord, P. C.)

As the length of the term for which lodgings are let seldom exceeds or even extends to a year, it is rarely the case that a six months’ notice to quit is necessary to be given by the party wishing to determine the tenancy. This can only happen when it is clearly understood that the tenancy is from year to year. But if the taking be for less than a year, as for a quarter, a month, or a week, which may be presumed from the rent being paid at the lapse of those terms, or other circumstances, the length of notice will be regulated accordingly, for the terms of the tenancy, and of the condition of the notice being that of the term. Unless the lodger gives up possession paying the rent for a whole term in ad-
vance, notice must always be given, and he will not be released without discontinuing the payment of the rent. Thereby just, of his goods being distrained for his landlord’s rent.

A contract to let lodgings being a contract for land under the Interpretation of the Statute of Frauds, unless such contract be in writing and witnessed, it cannot be enforced.

Lodgers are entitled without special contract to the use of such things as, though situated in another part of the house, are necessary to their convenience, as the knocker, door-bell, skylight, &c.

It has been held that a covenant by the lessee not to under-
let, is not broken by taking in a lodger, and on this ground may be rested the right of the original landlord to enter and distrain the goods and chattels of the lodger for arrears of rent due from the lessee, it being considered that the occupa-
tion of the lodger is that of the lessee. The lodger however can resort to his right to recover against the lessee for the loss so incurred.

The 7 & 8 Geo. IV. c. 29, § 45, protects the property of those who are not occupants of the premises from perjury in making it felony for the person in occupation to steal or ap-
propriate any chattel or fixture allowed to be used in any house or lodging.

(For a relating to this subject see Woodfall, Landl-
ord and Tenant; and Coote, Landlord and Tenant.)

LOGAN, JOHN, was born at Fain, in the county of Edin-
burgh, in 1748. He was the son of a small farmer, and, being destined for the church, entered at the University of Edin-
burgh; after which he became tutor to the late Sir John Sinclair. In 1773, almost immediately on being licensed as a preacher in the Established Church of Scotland, he was appointed to be one of the ministers of the town of Leith. In 1770 he had edited the posthumous poems of his friend Michael Bruce, incorporating with them some pieces which he claimed (and probably justly) as his own, and among which was a little Ode to the Cuckow. His poetical talents were further shown by several pieces of sacred poetry, some of which are inserted in the collection of hymns and paraphrases of Scripture annexed to the psalmody of the Scottish church. In 1779, patronized by Blair, Robertson, and other literary men, he delivered in Edinburgh a course of Lectures on the Philosophy of History; the reputation of which justified him next year in aspiring, though unsuccess-
fully, to the Professorship of Universal History in the Uni-
versity. Outlines of a part of his lectures were published under the title of ‘Elements of the Philosophy of History, for Lectures on the Church, Vol. I.’ and ‘Notes on the Church on the Government, Manners, and Spirit of Asia;’ and a vol-
ume of Poems, which reached a second edition before the year was closed. Logan, not a learned divinity, or a very pro-
found thought, but a man of sound and practical education, popular preacher. But his poetical endowments, strongly
lyrical in their tendency, were the highest he possessed; and unfortunately he was tempted to apply these in a path where he was not called to indirect and the relief. In 1768 he

informed and caused to be seated in

Edinburgh a tragedy called. 'Ramsmead,' which had been rehearsed at Cockburn, but refused a licence by the Lord Chamberlain. This publication brought on him the anger of his Presbyterian associates; and other

annuities, aggravated by an hereditary tendency to hypo-

chondria, served to increase the fate of the poor from which

he quitted his parochial charge and repaired to London. There,

retaining by agreement a part of his clerical income, he ed-

cated his livelihood by literary labour, writing paper for the

'Edinburgh Review,' and contributing to the first of the series which was one "A Review of the principal Charges against Mr.

Hastings," which brought on Mr. Stockdale, the publisher, a

prosecution for breach of privilege; the other was a useful

summary, entitled 'A View of Ancient History, including

The Progress of Literature and the Fine Arts, by William

Rutherford, D.D., Master of the Academy at Uxbridge,' 2

vols., 8vo. He died in London on the 28th of December, 1748.

His friends Drs. Blair, Robertson, and Hardy, published a

volume of his Sermons in 1790, and a second in 1791. These

sermons long enjoyed very great popularity, and have been

several times reprinted. They are among the most

scintillating that the Scot's has produced. Mr. Stockdale's Edition of his

poems, with an account of his life, appeared in 1805; and the

poems are included in Dr. Anderson's collection.

LOGARITHMS, Thirteenth Edition. The process was suggested by the celebrated Gauss for supplying an inconvenience connected with the use of logarithms described in § 21 of the following article. Though they have been suggested more than twenty times, they are only beginning to receive the attention which they merit.

If \( \log a \) and \( \log b \) be given, and \( \log (a + b) \) or \( \log (a - b) \) be wanted, the ordinary tables can only be applied by finding \( a \) and \( b \) from their logarithms, adding or subtracting them as found, and then finding the logarithm of the sum or difference. This requires three uses of the tables, and one process of addition or subtraction. Gauss's table substitutes one use of a table, and two processes of addition or subtraction. When the above necessity occurs only now and then, it may be hardly worth while to have recourse to such a table; but in any series of calculations in which the determination of \( \log (a \pm b) \) from \( \log a \) and \( \log b \) is a frequent constituent part, the table is a very great relief.

The construction of the table is as follows: There are three columns, styled A, B, C: the first, A, containing the

arvors of \( \log a \text{ and } \log b \text{, being } a \text{ and } b \) from their logarithms, adding or subtracting them as found, and then finding the logarithm of the sum or difference. This requires three uses of the tables, and one process of addition or subtraction. Gauss's table substitutes one use of a table, and two processes of addition or subtraction. When the above necessity occurs only now and then, it may be hardly worth while to have recourse to such a table; but in any series of calculations in which the determination of \( \log (a \pm b) \) from \( \log a \) and \( \log b \) is a frequent constituent part, the table is a very great relief.

The construction of the table is as follows: There are three columns, styled A, B, C: the first, A, containing the

arvors of \( \log a \text{ and } \log b \text{, being } a \text{ and } b \) from their logarithms, adding or subtracting them as found, and then finding the logarithm of the sum or difference. This requires three uses of the tables, and one process of addition or subtraction. Gauss's table substitutes one use of a table, and two processes of addition or subtraction. When the above necessity occurs only now and then, it may be hardly worth while to have recourse to such a table; but in any series of calculations in which the determination of \( \log (a \pm b) \) from \( \log a \) and \( \log b \) is a frequent constituent part, the table is a very great relief.

many any system of tables in part... There are many
reasons against our inserting the table of logarithms itself
in a large work of reference, as was frequently done a century
ago: we are pretty certain that it would not be used.

1. The object of logarithms is the performance of the
addition and subtraction of quantities in the following
ascending scale by means of the more easy one which precedes it:

Addition, Multiplication, Raising of Powers.
Subtraction, Division, Extraction of Roots.

Thus multiplication is reduced to addition, division to
multiplication, division to subtraction, extraction of roots
to division.

2. The sum of the logarithms of two numbers gives the
logarithm of their product, the difference of two logarithms
gives the logarithm of the quotient, and so on. These rules
are best expressed in symbols, thus:

\[ \log(A + B) = \log(A \times B) \]
\[ \log(A - B) = \log\left(\frac{A}{B}\right) \]
\[ \log(A^n) = n \times \log(A) \]
\[ \log(A + B) = \log\left(\frac{A}{B}\right) \]

3. The logarithm wanted is taken partly from a table,
partially from the one remembered rules. The integer part
of the logarithm is found by the rule; the fractional part by
the table.

4. The integer portion of the logarithm is called the
characteristic of the number: thus \(21673.3\) has 3 as the log
arithmetic of its logarithm, and \(21673.3\) is the characteristic of \(21673.3\). It is very
common to call this the characteristic of the logarithm itself;
but it is better to find this application upon it in connection
with the number from which it arises.

5. The characteristic of a number depends entirely upon
the place which the decimal point occupies. But the rest, or
fractional part, of the logarithm of that number depends upon
the significant figures only of the number, and has no
connection with the meaning which those figures con
tain by their position relatively to the decimal point. Thus \(21673, 21673, 21673, 21673.000000\), &c. are numbers
with different characteristics, or different integral portions in
their logarithms. But the fractional portions are the same in
the logarithms of all, namely, \(\log 3 = 0.53592\).

6. The characteristic of a number may be either positive
or negative. For our present purpose, it will be sufficient to
draw the rules for using these quantities, directing the reader
who is not used to the distinction to try to explain them by
considering positive quantities as gains, negative quantities
as losses; addition as junction, subtraction as removal. Thus
the addition of a positive quantity (annexation of a gain) is
the same thing as the subtraction of a negative quantity
(a loss), and so on. The following examples will illustrate this; the negative quantity being distinguished from
the positive one by a bar drawn above it:

| 8 and 5 make 3. | 2 from 3 gives 1. |
| 8 and 11 make 3. | 2 from 3... 5. |
| 2 and 7 make 9. | 3 from 2... 5. |
| 4 times 5 is 24; | 3 from 2... 1. |
| carry 8, which gives 21. | 8 from 3... 5. |

7. The rule for finding the characteristic is as follows:
When there are significant figures before the decimal point,
the characteristic is one less than the number of them. But
when the significant figures begin after the decimal point,
the characteristic must be marked negative, and must point out
the place in which significance begins. Thus the characteristic
of \(2791386\) is 3; that of \(17462\) is 4; that of \(20.137\) is 1;
that of \(9.899\) is 0; that of \(-7.63\) is 1; that of \(0.918\) is 2,
that of \(0.00007\) is 5.

8. It is worth while to remark that this broken rule, as it
seems to require subdivision only on account of the
notions generally attached to the decimal point, which is
treated as if it were one of the places of the number. But if
the decimal point were, as it ought to be, considered as part
and parcel of the number's place, so that \(12.84\), for instance, is
not \(1 \times 2 \times 8 \times 4\), but \(1 \times 2 \times 8 \times 4\), then the
two rules might be given under one, as follows. The charac-
teristic of a number is the number of places by which the
first significant figure is distant from the unit's place; and is
positive when that first figure falls to the left, negative when
to the right. Thus in 1284 • 567 or 1284 (• 6) • 567 it is 3; in
0.0009 or (0 • 0) 0009 it is 4.

9. A mixed number, such as \(5 \cdot 9274\), is thus multiplied
and divided:

\[ \frac{5 \times 9274}{6} = \frac{9274}{6} \]
\[ = 1546 \]
\[ \text{in multiplication, the multiplication of the negative figure}
\text{produces a negative result, and the carriage from the positive}
\text{part goes in diminution of this number. The last step is:—}
\text{6 times 3 is 18, and 6 is 15. In division, a divisible figure}
\text{must be sought above the negative characteristic, not below it;}
\text{and the first unit's place, from the last, must be afterwards carried
to the right in the usual way.}
\text{Thus when \(21116\) is divided by 5, the first step is:—5 is}
\text{contained in 25, 5 times, carry 4; then 6 is contained in 41,
8 times, &c.}
\text{5 \cdot 21116 = 115 \cdot 521 \cdot 1050 \cdot 606}
\text{5 \cdot 823 = 1 \cdot 929 \cdot 4 \cdot 361}
\text{5 \cdot 823 = 1 \cdot 929 \cdot 4 \cdot 361}
\text{10. The decimal part of the logarithm is taken out of the}
\text{figures. These are not complete logarithms, which could not
be given, since the real logarithms are generally incommensurable
decimals. The only numbers which have logarithms capable
of finite expression (in the system commonly used) are those
\text{5 \cdot 21116 = 115 \cdot 521 \cdot 1050 \cdot 606}
\text{5 \cdot 823 = 1 \cdot 929 \cdot 4 \cdot 361}
\text{10. The decimal part of the logarithm is taken out of the}
\text{figures. These are not complete logarithms, which could not
be given, since the real logarithms are generally incommensurable
decimals. The only numbers which have logarithms capable
of finite expression (in the system commonly used) are those
\text{5 \cdot 21116 = 115 \cdot 521 \cdot 1050 \cdot 606}
\text{5 \cdot 823 = 1 \cdot 929 \cdot 4 \cdot 361}
\text{10. The decimal part of the logarithm is taken out of the}
\text{figures. These are not complete logarithms, which could not
be given, since the real logarithms are generally incommensurable
decimals. The only numbers which have logarithms capable
of finite expression (in the system commonly used) are those
\text{5 \cdot 21116 = 115 \cdot 521 \cdot 1050 \cdot 606}
\text{5 \cdot 823 = 1 \cdot 929 \cdot 4 \cdot 361}
12. To find the logarithms of numbers and the numbers to logarithms, from the four-figure table, proceed as follows:—

From inspection of the number, take the proper characteristic, and then note the first four significant figures. In the row which begins with the first two, find the figures which are in the column headed by the third; and add to them the figures out of the side table which are in the column headed by the fourth.

For instance, required, as well as it can be given from a four-figure table, the logarithm of 4275898*116. The characteristic is 6; and the first four significant figures are 4276 (reading 568 rather than 437). In the row 42, and under 7, we see 6304, and in the side table opposite to 6 in 6, and 6304 + 6 = 6310. Hence 6310 is the logarithm of 4275898*116, as far as the four-figure table will give it. Similarly the logarithm of 4 (which must be read 400) is 0696, that of 400 is 26835, that of .04179 is 27630.

To find the number to a logarithm, in the four-figure table, use the decimals of the logarithm with the antilogarithmic table in the manner as the four significant figures of the number were used in the other table to find the logarithm; and then settle the place of the decimal point by means of the integer of the logarithm. The four-figure table goes into so small a space that it is worth while to print an inverse table of antilogarithms, or of numbers to logarithms; of which table we have also given a specimen above. Thus the number to the logarithm 5.0324 is required, we neglect 5, and, going into the anti-table with .0324, opposite to .02 and under 3 we find 4198, and under 4 in the side table we find 4. Hence 4198 + 4 or 4202 are the first four significant figures of the number required; and its characteristic is 4; whence 4200 is the number to the logarithm, as near as the four-figure table will give it. Similarly the number to .0111 is 4.084, that to .0200 is .09477, that to .06000 is 391000000.

We give an instance of the application of each of the rules in § 2. Let it be required to find, as nearly as four-figure tables will do, 60; the product of 17789 and 80; the quotient of 17.293 divided by 942942; the eighth power of 1.9273, and the eleventh root of 79005565918. The processes are as follows:—

| Log. of 17789 (say 17800) | 4.2594 |
| Log. of 68426 (say 68430) | 4.8231 |

Log. of product 9.0572

Answer 1129000000 from the table.

Error 144059, about .0010 of the whole.

Again, log. 17.293 (say 17.29) 1.2377 Subtract log. .942942 (.9429) 1.9745 Log. of quotient 1.9769 Answer 18.33.

log. 1.9973 (say 1.997) 0.2849 multiply by 8

log. of (1.997) 2.2792 Answer 190.2.

In raising powers, the errors are generally larger than in other processes, seeing that the necessary error of the logarithm is multiplied as many times as the logarithm itself.

log 00005565918 (say 000055659) 7.4748 Divide by 11 1.6133 log 000055659 Answer 4105.

14. Before beginning to use five-figure tables, it is advisable to practise the formation of the tenths of numbers not exceeding 50, in the head. For instance, which is the nearest integer to 7-tenths of 37. The process at length would of course be 37

10389

— nearest integer 26

5.9

It should be done thus: Having multiplied 7 by 7, and got 49, subtract the units, and carry 2 as the nearest number of tens. Then add 5 to 21 obtained from the three. When 5 units are thrown away, consider the ten next above as the nearest. Thus 9-tenths of 45 should be considered as 41, not 40, and 6-tenths of 17 as 9, not 8. Similarly, 4-tenths of 31 is 17; 3-tenths of 19 is 6. But 2-tenths of 32 is 6; 7-tenths of 42 is 3; 8-tenths of 25 is 2.

15. In the specimen of the five-figure table will be seen four figures of number, followed by five figures of logarithms, and an additional column marked D, which contains nothing but the differences between the successive sets of five figures in the logarithm. This column D is referred to under the name of the column of tabular differences. To take the logarithm of a number, take the characteristic as before, and five significant figures of the number. Find the first four significant figures in the table, and take the five figures of logarithm odd, as many tenths of the tabular difference as there are units in the fifth significant. Thus to find the logarithm of 011217, we find 1121 in the specimen, opposite to which is 45891, with 38 for a tabular difference. Now 7-tenths of 38 is 27, and 61 and 27 is 88; so .04988 is the decimal part of the logarithm. Similarly if the significant of the number 11223, the decimals of the logarithm are .05011; also 11201 gives .04966; 11209 gives .04957; 58332 gives .76591; 65906 gives .76592; and so on.

16. There is no antilogarithmic table to a five-figure table; and the way of finding the number to a logarithm is as follows: Seek out among the logarithms the decimals next under the decimals of the given logarithm, and take the four figures of number belonging to them for the first four significant figures of the number. Find by how much the decimals just used fall short of the given decimals, and call this difference the unattained part. Annex a cipher to the unattained part, and divide by the tabular difference; the digit which most nearly expresses the quotient is the fifth significant of the number. For instance, what is the number to the logarithm 3.05016. Looking into the table, we find that the next under 05016 is 04999, opposite to 1122. The unattained part is 17; the tabular difference 39; and 170 contains 39 4 times more nearly than 5 times; so that 4 is the fifth figure. The five significant of the number required are then 11224; and, looking at the integer part of the logarithm, the characteristic is seen to be 3; whence .0011224 is the number to the logarithm, as correctly as five-figure tables will give it.
17. The four questions worked above with four-figure logarithms are thus worked with five-figure logarithms:—

<table>
<thead>
<tr>
<th>Number</th>
<th>Four-figure</th>
<th>Five-figure</th>
</tr>
</thead>
<tbody>
<tr>
<td>17798</td>
<td>4.258037</td>
<td>17.92932987</td>
</tr>
<tr>
<td>63436</td>
<td>4.002027</td>
<td>9.49290917</td>
</tr>
<tr>
<td>1128900000</td>
<td>9.052649</td>
<td>18.83631295</td>
</tr>
<tr>
<td>205231</td>
<td>4.063156</td>
<td></td>
</tr>
<tr>
<td>283690</td>
<td></td>
<td>24.2220</td>
</tr>
<tr>
<td>1.9273</td>

<td>61.3218</td>
</tr>
<tr>
<td></td>
<td>27.944</td>
<td>7.0940</td>
</tr>
</tbody>
</table>

20. The seven-figure tables have five figures of number, with seven decimals of logarithm; and the sixth and seventh significant of the number are to be provided for by means of the tabular differences. But as these tabular differences run to three and four places of figures, their tens are written down in small separate tables. [Proportional Parts, P. C.]

To take out a logarithm, take out the seven decimals belonging to the first five significant of the number, and add from the table of proportional parts the number opposite to the sixth significant, and one-tenth of that opposite to the seventh significant. Thus, to find the logarithm of 46517545, of which the first seven significant are 4651754, look in the table for 46517, and we have

<table>
<thead>
<tr>
<th>Table</th>
<th>459517542</th>
<th>6591787</th>
</tr>
</thead>
<tbody>
<tr>
<td>Do.</td>
<td>do.</td>
<td>3</td>
</tr>
</tbody>
</table>

So the logarithm required, as far as seven-figure tables will give it, is 8.6581772.

A little practice will enable the calculator to add together, without writing them down, the two contingents derived from the table of proportional parts. The computer must be careful not to miss the change of the third figure of a logarithm, which usually takes place in the middle of a line, though it can only be marked at the beginning. Thus, in the specimen of the logarithm of 45603 has the decimals 6599394, but that of 45604 has 6590296, not 6590295. Some mark is usually made to give warning that the change has taken place; but those whose work is so little alive to the circumstance as to stand much in need of this mark will often make the mistake in spite of it.

18. To take the logarithm of a given number out of seven-figure tables proceed as follows: Find the nearest decimals under the given decimals, and by subtraction find the unattained part. Take out the five number-figures belonging to the attained part, and for the first five significant of the number. Look in the table of proportional parts for the nearest under the unattained part, and take the digit opposite to it for the sixth significant. Annex a cipher to the remainder of the unattained part, and take the digit opposite to the result (or its nearest) in the table of proportional parts for the seventh significant. For instance, required the number to the logarithm 1.0590176:

\[
\begin{align*}
5065 & \quad \text{gives} \quad 6590125 \\
5 & \quad \text{gives} \quad 6590125 \\
3 & \quad \text{gives} \quad 6590125 \\
20 & \quad \text{gives} \quad 6590125
\end{align*}
\]

Number required 45.63533

21. More complicated questions may be directly solved by logarithms, that is, without requiring to seek the number to a logarithm until the end of the process, as long as the multiplications, divisions, involutions, and evolutions are not broken by additions or subtractions. Thus to calculate \( \sqrt[4]{a^b + c^d} \) we form for the logarithm of the answer

\[
\log (a^b + c^d) = 4 \left( \log a + \log b + \frac{c}{d} \right)
\]

But if additions or subtractions intervene, the process must be broken to produce the result; that is, the logarithmic process must be suspended, and the results exhibited in the manner for the performance of the additions and subtractions (unless indeed the logarithms described in the next article be employed). Thus to find \( \sqrt[4]{a^b + c^d} \) it would be necessary, not merely to form the logarithms of \( a^b \) and \( c^d \), or \( 2 \log a + \log b \) and \( c - \log b, \) but to find the numbers to them: these numbers being then added, and the logarithm of the sum being taken, half the last logarithm is the logarithm of the answer.

22. There is nothing in the trigonometrical logarithms more than is described in Trigonometrical Tables, P. C. Many young students, from seldom or never using the actual sines, cosines, &c., of angles, but only their logarithms, are apt to confound the former with the latter.

23. Some little additional correctness may be obtained by annexing to the use of the tables, as given above, an attempt to add something for the want of the seven more figures after the decimal point. Thus, suppose it required to find the logarithm of 11.374928. In the four-figure table 113 has 0531 and .77 adds 26. The next figure is 4, which, had it been the fourth significant, would have been carried to 15; but being the tenth of 15, or its nearest integer, 2. Hence we add 28 instead of 26 to 0531, and get 0559 instead of 0557, as a nearer approach to the logarithm. Again, in the five-figure table, 1137 gives 05576, and the tabular difference is 38. The 4 gives 15, or 4-tenths of 38, and the 9 ought to give 9-hundredths of 38, or 3. Consequently 15 + 8, or 18, is added, giving 05654. Had 49 been read as 50, in the usual way, 10 would have been added. In the seven-figure table 11374 gives 0559192; 9 adds 845, the 2 should add the tenth of 77, and the 8 should add the hundredth of 305: hence 3 more should be added than arises from the figures 92. This plan may be carried farther, when the required accuracy is desirable, especially in the four-figure table. It is most useful when the tabular differences are large, that is, at the beginning of the table.

24. It may sometimes save a mistake if the computer remember that the significant of the number generally read less than those of the decimals in the logarithm. Thus 300... has 301..., for the decimal figures of the logarithm. It is not so however at the beginning of the table, and the figures of the logarithm overtake those of the number between 13712 and 13713.

25. The rule of the characteristics, when well learned, furnishes one of the easiest modes of assigning the place of a decimal point in a common division. For example, in dividing 30017643 by 018416, the characteristics being 3 and 2, we shall have to carry 1 to 2, because the significant of the divisor is 18, greater than 17. Take 1 from 3, which leaves 2, the characteristic of the quotient, which has therefore -0 before its significant. The rule is, to find the characteristic of the quotient, from that of the dividend subtract that of the divisor, carrying 1 if the significant of the divisor be greater than those of the dividend.

26. In using the trigonometrical tables, or any other, careful attention must be paid to the right choice of the method of interpolation, either to the argument and its quadrant (Tables, P. C.), or the numbers with which we enter the table and those which we take from it, increase together or diminish together, then the alterations introduced by the table of proportional parts consist in adding to either for every addition to the other, and subtracting for every subtraction. But if...
The tabular result diminish as the argument increases, then every addition to the one is accompanied by a subtraction from the other, and vice versa. In the tables of logarithmic cosines and cotangents, the young computer frequently falls into the common error of taking the wrong root. Thus the logarithm of the cosine of 84° 9′ in a five-figure table is 0.9082, and the tabular difference is 154, diminishing. Hence the log cosine of 84° 8′ is not 0.90828 + 0.00065, but 0.90829 + 0.00062. And if we ask for the angle whose log cosine is 0.90840, we find the next underneath this in the table to be 9.09328, and 2 for the unattained part. Divide 220 by 124, and 2 is the nearest integer. But the angle required is not 84° 9′ + 0° 2′, but 84° 9′ + 0° 2′, or 84° 9′ - 8.

27. The equation \( e^x = b \), in which \( x \) is unknown, is solved by taking the logarithm of both sides, which gives \( \log x = \log b + x \). The process may perplex a beginner when the quantities have negative integers. We therefore subjoin an example. Let it be required to solve the equations

\[
\begin{align*}
\frac{2}{3}x & = -0.0163 \\
182 & = -6
\end{align*}
\]

(The reader is supposed to know the complete interpretation of algebraical exponents.) We have then

\[
x = \log (-0.0163) + \log \left( \frac{2}{3} \right) = 3.21219 + 1.75696
\]

\[
y = \log \frac{182}{6} = 17.8715 + 2.26007
\]

Now throw the three logarithms which have negative integers into the more usual algebraical forms.

\[
\begin{align*}
-2.21219 & = -5.75696 - 1 \\
-2.26007 & = -7.7515 1
\end{align*}
\]

Or 1 - 2.21219 - 2.26007 = -0.998181.

And make the divisors, which give for the quotients 1 - 471, and -0.998181, or

\[
\begin{align*}
\frac{2}{3}x & = -0.0163 \\
182 & = -6
\end{align*}
\]

LOGGAN, DAVID, a line-engraver and designer, of considerable eminence in England in the time of Charles II., was born at Danzig in 1638. He appears to have first learnt his art from Simon de Pass in Denmark, and to have worked subsequently with Hondius in Holland. He came to England during the Commonwealth, and spent some time in engraving heads in London. But his first work of consequence in this country was a set of plates of the colleges of Oxford — *Oxonia Illustrata*, for the sale of which he had fifteen years' privilege; he executed afterwards a similar series of the colleges of Cambridge. He also engraved on eleven folio plates *Haliae Academiae Oxoniensis Heroes ad Servitum*; Loggan is himself entered on the books of the University, in the matriculation registry there is the following entry —

*David Loggan Gedanensi, Universitatem Oxon. Chalcographus.*

He married Mrs. Jordan, of a good family, near Witney, Oxfordshire, by whom he had a son, who became a fellow of Magdalen College, Oxford. He died at his house in Leicest-

Loggan engraved many portraits of illustrious persons in the time of Charles II., many of the drawings of which were executed in lead by himself from the life,—as George, prince of Denmark; the Duke of Albemarle; the Earl of Clarendon; the Earl of Argyle; the Duke of Ormond: the Lord Keeper Guildford; Archbishop Sanctor; the Bishops Mew, Seth Ward, and Pearson; and many others. There are prints also by Loggan of Archbishops Usher and Boyle, and of Bishops Sprat of Rochester, Lake of Chichester, Crew of Durham, Compton of London, Gunning of Ely, Reynolds of Newcastle, and Archbishop of St. Asaph. He engraved also three portraits of Charles II., in one of which the king is leaning his hand on Archbishop Sheldon; James, duke of York; the Duke of Monmouth; the Queens Catherine and Henrietta Maria; Pope Innocent XI.; the Earl of Derby, Sir Edward Coke, Sir John Chardin, Thomas Barlow, Titus Oates, and many others, which are enumerated by Vertue.

Loggan had the following assistants—A. Blooteling, G. Valk, and Peter Williamson; the first two came from Holland with Loggan.

(Vertue, *Catalogue of Engravers*, &c.)

LOGIC *[Organon, F. C. and P. S.]*

LOIR, NICOLAS, a distinguished French painter and etcher, was born at Paris in 1624. His father was an eminent jeweller, and he placed Nicolas with Sebastien Bourdon, and sent him afterwards, in 1647, to complete his studies in Rome. Here Loir studied chiefly the works of N. Poussin, and so carefully that in some instances it is said to be scarcely possible to distinguish Loir's copies from the originals. He had great facility of execution, and excelled in various styles, as history, landscape, and architecture. He also composed with elegance, and his colouring is very agreeable; but his design is somewhat affected, and is not always vigorous or correct in its outline.

He painted at Rome an excellent picture of Darius opening the Tomb of Semiramis, which obtained him a great reputation. He returned to Paris in 1649, and afterwards employed by Louis XIV., at the Tuileries and at Versailles. He painted two apartments in the Tuileries—the Antechamber of the Roy and the Salle des Gardes, where, by the mythical representation of the sun and other figures, he illustrated the distinctive character of the life and reign of Louis XIV.; and so far to the monarch's satisfaction, that he obtained by these works a life-pension of 4000 francs.

In 1663 he was elected a member of the French Academy of Painting, and he presented on the occasion, as his reception-piece, a picture representing the Progress of Painting and Sculpture during the reign of Louis XIV.; but his master-piece is considered Cleobis and Biton drawing their Mother in a chariot to the temple of Juno, from the story of Herodotus (i. 31); Loir himself has made an etching of it. Another of his best works is the Palace of the Emperor Louis and the Magician of sight, in the Cathedral of Notre Dame at Paris. He excelled in painting women and children, and particularly the Virgin Mary. He is said to have designed twelve Holy Families in a similar way, which did not pass so much for a genius alike. He died at Paris, rector of the Academy, in 1679. Loir's own etchings amount to 160 pieces, which, together with 50 engravings after his works by other artists, make a total of 239 prints. A portrait of the latter was engraved by his brother Alexis Loir.

Fellinien describes several of the works of Loir at considerable length; his account of this painter contains also some curious digressions relating to the superstitions of the modern Romans, and other matters. Fellinien and Loir were at Rome together, and Fellinien's dates have been for this reason adopted in this article, where they differ from those of D'Argenville and Gault de Saint-Germain.

(Fellinien, *Entretains sur les Vies et sur les Oeuvres des Peintres*, &c.; D'Argenville, *Abridge de la Vie des plus fameux Peintres*, &c.)

LOMBARDUS, LAMBERT, the designation of a painter whose actual name is not known. He is sometimes called Lamprecht Sustermann or Susterman, and, according to some, Lambert van Ouwerkerck. He is supposed to have been born in France, and his birth is equally unknown: it is said to be Liege or Amsterdam, more probably Liege, as he settled there after his return from Italy in 1658, and he died there in, 1660, aged fifty-four. Vase in the Tabet Collection, July 5, 1659, has Lanberry's name, distinguishing all of the Flemish painters, and styles him a great letterato, a judicious painter, and an excellent architect; but his account of him is contradictory; he had it from D. Lampertius, who wrote the pamphlet *de Vita Lucis in Latine*; it was published at Bruges in 1556, five years after his death. Lombardus studied under Jan de Maiause before he visited Italy. Frans Floris, Hubert Goltzius, and Willem Key were his scholars. His works consist chiefly of drawings with the pen in chiaroscuro; his coloured paintings are scarce; there are two or small dimensions in the Gallery of Berlin; there is a Pietà in the church of Pincensteck at Munich, which is to be attributed to Daniel de Votterra. Lombardus's style is strictly Italian: he is said to have studied under Titian at Venice, and he lived some time in Rome. The surname of Lombardus was probably given to him by his Flemish countrymen on account of his style, which, different from their own, they distinguished as the Lombard style, Lombardy being formerly the general name for the northern part of Italy.

There are many prints supposed to be after Lambert's designs, some of which are marked Lam. Lombardus, and others Lam. Sussius; and it is not yet decided whether these names indicate one or two artists; Heincken considers them as two, and Van Mander and Van Syssius as one, making no allusion to Lombardus. In a note to De Yongh's edition of Van Mander, Sussius is styled the pupil of Lombardus.

LONDONDCY, ROBERT STEWART, MAR-
QUESS OF, was born at the family seat of Mount Stewart, in 1724, and lived till 1798, (the same year which gave birth to the Duke of Wellington and to Napoleon Bonaparte.) His father, of the same names, after representing the county of Down for many years in the Irish parliament, was made Baron Stewart of Londonbury in 1769, Viscount Castlercagh in 1779, Earl of Londonderry in 1796, and Marquess of Londonderry in 1816—all in the peerage of Ireland. Robert was his only child that survived by his first wife, and was the eldest son of the 18th of Octob. 1769, Francis Marquess of Hertford, whom he married in 1766, and who died in 1770.

The estate of Mount Stewart was purchased by Mr. Alexander Stewart, father of the first marquis, who sat in the Irish parliament for the city of Londonderry. Before this the family were known as Stewarts of Ballylawn in the county of Donegal, of which property John Stewart, the great-grandfather of Alexander, the first of them who settled in Ireland, obtained a grant from King Charles I. There seems to be ground for believing that he was nearly related to some ennobled branch of the Stewarts: but the connexion appears not to be distinctly traceable, and is variously given in the several accounts.

The descent of the family is common enough, and, if anything, rather assumed to be, from Sir Thomas Stewart of Leuchars, who lived in the latter part of the fifteenth century, the ancestor of Lord Blantyre, and a younger brother of Sir Alexander Stewart of Dalwinton and Garlies, the ancestor of that Earl of Galloway. John Stewart is stated to have emigrated to Ireland about the time of the death of James I.

The subject of the present notice received the first part of his education at the free grammar-school of Armagh; whence he was removed in 1766 to St. John's College, Cambridge. He was not yet of age when, on his father being raised to the peerage in 1769, he offered himself for the vacant seat in the representation of the county of Down, and was returned, though not without a severe contest, which lasted nearly three years, and is said to have been 25,000l. or 30,000l. Nor did he come in without pledging himself, in contradiction to what had hitherto been the family policy, to the cause of parliamentary reform, which had for some time been a popular watchword in Ireland. For three or four years, according to his word, he was considered as belonging to the party of the opposition, though to the aristocratic and more moderate section of it. He very early began to take part in the debates.

His conversion from liberalism seems to have taken place about 1788 or 1794; and it may be fairly considered to have been the result of a conflict with the more alarming aspect which popular politics in Ireland were every day assuming. Up to this time he appears to have been universally regarded as an unusually amiable and agreeable young man; after his elevation to a peerage, his candor was commonly represented as a prodigy both of perspicuity and heartlessness.

In the summer of 1794 he was returned to the British parliament for the borough of Tregony, and, after remaining absent for a session he made his maiden speech in the House of Commons in seconding the Address on the 29th of October, 1795. It is said to have greatly disappointed the expectations excited by the reputation he had brought over with him. He was to the last a remarkably unassuming speaker; at one time rising above, at another time—sometimes on the same night—falling below his ordinary or average style of execution in a degree so considerable as to be creditable, and the greater wonderful in a person of so much nerve and self-possession.

He does not appear to have ever spoken again during this parliament, which was dissolved after the close of that of its sixth session, in May, 1796. That year he became Viscount Castlercagh; and he was again returned to the next British parliament, which met in September, for the borough of Oxford. But he returned his seat in July, 1797; upon which he was re-appointed to the Irish parliament for the county of Down, and was made Keeper of the Privy Seal for Ireland. In the beginning of 1798 he was appointed Secretary to the Lord Lieutenant in Ireland, and remained in the office till 1812; and from that date he may be regarded as having been distinctly the ministerial leader in the Commons. The credit or discredit of the measures adopted for the suppression of the Rebellion, which broke out and was put down in this year has also been commonly assigned to him, although it does not appear that he really did more than carry out the system which he found already in action when he came into office. He was no doubt one of the principal managers of the project of the Union, which followed two years after.

He was returned to the English House of Commons in 1796, for one of the new offices of the Imperial parliament, which met in February, 1801; and also to the second, which met in November, 1802; though upon the latter occasion not till after a severe struggle with the interest of the Downshire family, whose hostility had been principally caused by the dismissal of the late marquesses from the command of his militia regiment and the lord-lieutenancy of the county for his opposition to the Union.

In the beginning of 1802 he had been made a privy counsellor of Great Britain, and President of the Board of Control; and he retained that office after Mr. Pitt retired and throughout the Addington administration. After Mr. Pitt returned to power, Viscount Castlercagh was, in July, 1805, promoted to be one of his majesty's principal secretaries of state (taking the department of War and the Colonies). He was now, however, thrown out of the representation of Down, and was obliged to take refuge in the borough of Boroughbridge, for which he was returned in January, 1806, on a vacancy made by the death of the Hon. John Scott, son of Lord Elgin. He resigned with the rest of the cabinet on the death of Mr. Pitt shortly after this; and to the next parliament, which met in December, with a new ministry, he was returned for the borough of Plympton Ernes.

Upon the dissolution of that ministry, in April, 1807, Lord Castlercagh was reappointed to his former office of Secretary of State; and he was again returned for Plympton to the parliament which met in May of this year. He was now regarded as the undisputed leader of the opposition to the war; and the failure of the disastrous expedition to Walcheren in the summer of 1809 not only drew upon him much general unpopularity, but involved him in a personal quarrel with his colleague Mr. Castlereagh, the Secretary for Foreign Affairs, which led first to the resignation of both, and then to a duel between them, in which Canning, on the second fire, was severely wounded. In the earlier part of this same year, however, some delay was necessarily involved in the formation of committees of the Commons which charged Lord Castlercagh, along with other persons, the one with corrupt practices in obtaining the returns of members for Irish boroughs, the other with irregularities in the disposal of Indian patronage.

Lord Castlercagh remained out of office till February, 1812; when, on the resignation of the Marquess Wellesley, he was appointed Secretary of State for the Foreign Department. After the death of Mr. Perceval, which followed in May, he was regarded as ministerial leader in the Commons. To the new parliament which met in November, 1812, he was once more returned as representative for the county of Down; and he also retained that seat in the next two parliaments, which met in August, 1816, and in April, 1820. The return to office of Mr. Canning, however, in 1816, had relieved him from some of the responsibilities of the public business in the House, till that gentleman again retired in 1820.

Meanwhile in the end of the year 1813 Lord Castlercagh had gained a great victory. France having opened with the French government at Chatillon, which however broke off after a few weeks without any result; and he had also appeared as representative of the King of England at the Peace of Paris, in May, 1814; at the Congress of Vienna, in October of the same year; at that of Paris after the battle of Waterloo in the following year; and at that of Aix-la-Chapelle in 1818. On such occasions as these, his fine presence and grave manner showed him to be the equal of any of his predecessors in the same station; and he likewise attended George IV. to Ireland in 1820, where he had for the moment the gratification of being extremely popular among his countrymen. He had been made a Knight of the Garter in the reign of the present King of England; and was succeeded by his son, Viscount Castlercagh, by the death of his father on the 8th of April, 1821.

Lord Londonderry died by his own hand at his seat of North-Croydon Place, in the county of Kent, on the 12th of August, 1822, at the age of 72. He was occasionally observed for some months, and for a few days before the melancholy catastrophe his extreme irritability and the symptoms of a morbid mind were discernible; and from that period the notice of his domestic and friends. On the 9th, the Duke of Wellington wrote to Dr. Bankhead:—"I sincerely hope that you will contrive, by some pretence, to go down to his lordship. I have no doubt he is very unwell; he appears to me to have been exceedingly harassed, much fatigued, and gro-

Digitized by Google
worked during the late season of parliament; and I have no doubt he labours under mental delirium; at least this is my impression. The coroner's jury which sat upon the body brought in a verdict of lunacy. He had married in 1794 Lady Emily-Anne Hobart, youngest daughter of John, second Earl of Buckinghamshire, in which society and the title went to his half-brother, the present Marquess.

There was no brilliance of intellect in Lord Londonderry, scarcely even the ordinary amount of literary cultivation and taste. But speaking the truth, he had sometimes, perhaps, been always inelegant and slowly, and occasionally so to a ludicrous degree. To any acquaintance with the philosophy of politics he made no pretension; nor did even the ministerial in victor in the contest. But he had great business talents; and that qualification, with his charm of manner, fitted him admirably for managing men, and was the main secret of his success in life. Something too, however, is to be attributed to certain moral qualities which he possessed. Whatever difference of opinion might be entertained about some of his political proceedings, or acts done in his political capacity, his personal character admitted by all who knew him to be that of an honourable and high-minded man, upon both whose firmness and fearlessness every reliance could in all circumstances be placed. His integrity in the great and highest walks of life might almost be said to contrast with the amiss of his manner.

(Memoir in Annual Register for 1822, which, however, abounds with omissions and inaccuracies; Parliamentary Hist. of George IV, vol. 4.)

LONGHI, GIUSEPPE, an Italian painter, and one of the most distinguished engravers of the nineteenth century, was born at Monza in 1766. His father was a silk-mercer, and from his own hand the boy, Giuseppe, was taught engraving. At the age of twenty, Giuseppe was finally placed with the Florentine Vincenzo Vangeliati, professor in the Brera at Milan, under whom he learned engraving. He studied afterwards some time in Rome, where he became acquainted with Raphael Menga, one of the best Italian engravers of that time. After having worked as a very celebrated engraver; and Longhi soon obtained a reputation himself by his print from the Genius of Music, a picture by Guido in the Chiigi Palace. It was then that, as the pupil of one of the chief employed in miniature painting, until he was ordered by Napoleon to make an engraving of Gros's portrait of him; and he was appointed about the same time (1798) to succeed Vangeliati, deceased, as professor of engraving in the Academy of the Brera, to which, during Longhi's professorship, many distinguished engravers of the present time in Italy owe their education. It was one of Longhi's first principles to make the monosubervient to the end, and not the end to the means: he always depreciated cleverness of line as a principal object, and in his own works manual dexterity is invariably subordinate to conforming to the general character, colour, and texture of the original, and the etching-needle was accordingly his chief instrument. He excelled in light and shade. Among his principal engravings are: The Baptism of Christ, the Oath of the Sposaitoli, or the Marriage of the Virgin, and a Holy Family, after the same; the Entombment, after D. Crespi; the Magdalen, after Correggio; the Madonna del Dago, after Da Vinci; Galatia, after Alban; and many heads, after Rembrandt. The Sposaitoli was engraved as a companion-piece, or pendant, to Morghen's large print of the Transfiguration, by Raphael. He commenced in 1827 to engrave the Last Judgment, by Michelangelo, from a drawing by the Roman painter Minardi, but he died without finishing it: it was however considerably advanced, and, if not already finished, will probably be completed some one of his distinguished pupils. The Madonna del Dago, a tapestry by Raphael, Longhi also left unfinished, but it was completed in 1834 by his pupil the Cav. Toschi. Longhi died of apoplexy in 1831. He was a Knight of the Iron Crown, and member of many academies.

Besides a few poems and other essays, there is a treatise on engraving, by Longhi ('La Calceograpia'), which has been translated into German by C. Harth; and contains a Life of him, by F. Löhren. A Life of him, also, with a list of his works, was published at Milan in 1831; and there are notices of him in the Kunsthstift, and in Nagler's Neues Allgemeines Lexikon. (3.)

LONGICORNES, the fourth family of tetrarmorous Coleoptera in Latreille's arrangement of insects. It includes a vast number of large and beautiful beetles, all remarkable for the length of their abdomen, which in many species are several times longer than their bodies. They inhabit woods, where the females deposit their eggs beneath the bark of trees, effecting the operation by means of a long, strong, horn-like ovipositor with which they are provided. The females are usually larger than the males. The larva lives beneath the bark of trees, according to the species in which it is found, and does much damage. The greatest assemblage of species and the largest forms are found in South America; but longicornes beetles are very generally dispersed. This family is divided into three great groups of which the genera Fruina, Cerambyx, and Lepista are the respective types.

LONC/ERA, a genus of plants named after Adam Lonicer, a German botanist, who was born in 1527 and died in 1556. He practised as a physician at Prague and later at Frankfurt-on-the-Main, and wrote a Herbal, which was merely a compilation of what had been done by others. There is also a John Lonicer mentioned who wrote a commentary on Dioscorides.

This genus is the type of the natural order Caprifoliaceae, and has the tube of the calyx 5-toothed, the corolla tubular, campanulate or funnel-shaped, with a 5-cleft usually irregular limb; 5 stamens; a filiform style, a capitate stigma; 3-seeded berries, and crustaceous seeds. The species are erect or climbing shrubs, with opposite exstipulate leaves and axillary flowers. There are about 60 species of Loniceræ, most of which have handsome flowers and emit a delicious perfume.

L. caprifolium, Goose-leek, or pale perfoliate Honeysuckle, has white whorled terminal and sessile flowers, deciduous leaves, glabrous; the leaves glabrous on both sides, the young leaves puberulous. The petals are pale perfoliate, the style glabrous. It has a twining stem, with white or purplish flowers and orange-coloured berries. It is a native of the middle and south of Europe, and is found in woods and thickets in many parts of England and the south of Scotland.

L. Periclymenum, the Woodbine, or Honeysuckle, has climbing branches, the leaves all separate, deciduous, somewhat downy, glabrous; the flowers subtended, sometimes the calyx-limb at the base, upper ones the smallest; the heads of flowers all terminal ovate, imbricated; the flowers fragrant. The flowers are pale yellow, the berries red, and accompanied with permanent bracts. This plant is in early times used for the suffers of the brain, and for serious powerful medicinal properties, but it is not now used. It is however extensively cultivated in the gardens and shrubbery of Europe on account of the delicious perfume of its flowers. This plant is the true 'woodbine' of the poets, and Milton has applied to it the name 'twisted ogilante.' This plant has obtained the name of woodland, a corruption of wood-bine, from its habit of twisting round the stems of trees.

Thus Shakspere says—

So hath the woodbine, the sweet honeysuckle, 

Gently winded through the maple.

The name honeysuckle is derived from the habit of children, who draw the corolla out of the calyx, and suck the collected honey from its nectar. Several varieties of this plant are recognised by botanists. All these are beautiful climbers and twining stems, some with fragrant scents, and others, as the polyanthus; a pole, or climbing and rambling amongst bushes, are very ornamental in gardens. It is a native of middle Europe, and very abundant in some parts of Great Britain.

L. Xiphiodes, Fly Honeysuckle, has 2-flowered woody peduncles as long as the flowers, the calyx-limb deciduous, the berries slightly connected at the base, the leaves oval, downy, the stem erect. The flowers are of a pale yellow, and the berries are scarlet. It is a native of nearly the whole of Europe, in thickets, hedges, and rocky places, and by the side of woods. It is found in the same situations, but is a rare plant, in Great Britain.

L. Tartarica, the Tartarian Honeysuckle, has a glabrous erect stem; cordate-ovate sub-acute leaves; the peduncles shorter than the leaves; the berries distinct when young and nearly globose, but at length connate at the base; flowers rose-coloured, short, somewhat gibbous at the base; the fruit black with one of the berries usually abortive: the peduncles 2-flowered. It is a native of Tartary, and is one of the most hardy of European shrubs, growing in the open air in the gardens of Petersburg and Stockholam. It is very common in British gardens and is valued much on account of its early leafing and flowering.

L. Therica, the Georgian Honeysuckle, is an erect plant with petiolate, cordate, roundish, tomentose or pubescent leaves; the peduncles 2-flowered, shorter than the leaves, the bracteoles oblong, eliased; the berries globose, blood-coloured, joined together to the middle globular, hairy, and the seeds bear a hairy coat...
LOMBO. [WEAVING, P. C.]

LOPHIADAE, a family of Acanthocephalans, named

Fecundus pediculatus by Cuvier. Their pectoral fins are so

constructed and placed as to perform the office of feet. The
Lophius piscatorius, or fishing-frog, is a British example.

Lophobranchii, a family of fishes in which the
gills, instead of being separated, are separated into small
round tubs, which are arranged in pairs along the branchial
arches, and covered by a large operculum, so fixed as to leave
only a single small orifice for the passage of the water out-

wards. The pipe-fish, Syngnathus, Hippocampus, Solenol-
atumus, and Pegasus, are the genera included in this family.

LOPHOTES. [TAXIODES, P. C. S.]  

LORANTHUS (from lorum, a 'strip of leather,' and
delos, the wound, referring to the wound-like linear
shape and leathery substance of the petals), a genus of plants the type of
the natural order Loranthacae. It has discotic or hermaphro-
dite flowers, the calyx cup-shaped, adnate, with an entire bor-
der of scales, the petals 6, linear, reflexed, and the stamens inserted
inside the middle of the petals; the filaments short, anthers glo-
bos; the style thickish; stigma simple; the berry globose, 1-
celled, 1-seeded. The species are evergreen shrubs para-
sial or arboreal.

1. Europeus, the European Loranthus, is a graceful much
branchied plant; the branches terete; the leaves opposite, petiole, oval-oblong; the racemes terminal, simple; the flowers without a]

LORDS ACT. [INSOLVENCY, P. C.]

LORENZETTI, AMBROGIO and PIETRO DI, two celebrated Italian painters of the four-

teenth century, were born at Siena about the year 1300.

They were brother, as we learn from the following inscrip-
tion formerly in the hospital of Siena: ' Hoc opus fecit Petrus
Laurenti et Ambrosius cujus frater, 1320.' It was attached to
pictures of the Presentation and of the Marriage of the Virgin,
which were destroyed in 1700; and was preserved by the
Cav. Pecini. This inscription explains the name given by
Vasari to Pietro, whom he calls Petrus Laurenti or Laurati,
which is evidently an erroneous reading of Petrus Laurentii —
Pietro di Lorenzo.

Some works of these painters still remain, though
the principal of their works, by Ambrogio, which is described
by Ghiberti (in Cod. Magliabecchiani, f. 8 & 9), is do-

stroyed. It was painted in the Mihorie convent at Siena,
and on the walls of the cloister, in the shape of saints, and
monks. In the first compartment a youth was represented
putting on the monastic costume; in another, the same youth
was repainted with several of his brother monks about to
set out on foot, and conversing about missions. In
these missions are already at their place of destination,
and are being chartered in the Sultan's presence, and are sur-

rounded by crowds of crowds, and the Sultan judges them to be hanged; a fourth, the young

monk is already hanged to a tree, yet notwithstanding he

continues to preach the gospel to the astonished multitude,
upon which the Sultan orders their heads to be cut off; the
next compartment is their ceremonial execution by the
sword, and is surrounded by hounds and horsemen; after the execution follows a great
storm, which is represented in all the detail of wind, hail,
lightning, and earthquake, from all of which the crowd are
protected by the Sultan and his nobles. For this picture it was
considered, is the cause of many conversions to Chris-
tianity. Such is the description of this picture by Lorenzo
Ghiberti, the first sculptor of his time, and he finishes it by
declaring it as a painted story of some perfect things: 'per una storia piu mi pare una maravigiosa cosa;' many
of the actors, he says also, appeared to be living beings.

There is still in the Sala delle Balestre, in the public palace
of Siena, a tempera painting of Peace, represented by a woman
within and without the city of Siena, with numerous inhab-

tants variously occupied in business and in pleasure. War
was likewise represented in this hieroglyph, but is now defaced;
there are however other allegorical works still remaining,
and Rumohr observes that what remain justify Ghiberti's
praises of what have disappeared, speaking with relation to
the time of their production, 1336.

Of the several pictures by Ambrogio Lorenzetti mentioned
by Ghiberti, only one remains—the Presentation of the Virgin
in the Temple, in the Scuole Regie, and in this some of

his works are equal to his earlier subjects. The Danae of

Ghiberti does not mention any works by Pietro Lorenzetti,
and there is only one authenticated work by him; it is in the
Sanza del Filone, a room against the sacristy of the cath-

dedral of Siena, an inscription on the wall over it says:

LORANITII, A. M. CIOCULLI.' It represents, according to Rumohr,
some passages from the life of John the Baptist, his birth,
etc. Vasari mentions many works by Pietro in various cities of
Tuscany, where he says his reputation was greater than

in Cinabre's or Giotto's. He attributes to him a picture of the
early fathers and hermits in the Campo Santo at Pisa; it is
engraved in Lasinio's 'Pitture del Campo Santo di Pisa.'

In 1314 two paintings, one of the Nativity, and another of
the building of the cathedral, in which he painted in fresco twelve stories from the life of
the Virgin, with figures as large as life and larger, but they have long since perished; they were however in good preserva-

tion in the time of Vasari, who completely restored them.

They speak of parts of them as superior in style and vigour to
anything that had been done up to that time.

The works of these painters, though relatively good, are
not exempt from any of the errors and defects of the prevai-
ling style in Italy previous to Donatello, Masaccio, and Ghi-

berti; and they display even some of the barbarities of the
lyceum school. Several pictures are attributed to them in

various places and collections, but wholly without evidence as to their

authorship.

(Vasari, Vita de' Pittori, &c.; Della Valle, Lettere

Sacer, Lanni, Storia Pittorica, &c.; and especially Rumohr,

Italiane, and Cambiaso, in which the two Lorenzetti are

treated of at considerable length.)

LOSS ISLANDS. [SIEGRA LEONIS, P. C.]

LOTO, one of the poets of Greece in the early

sixteenth century. He is supposed to have been one of the

scholars of the Bellini, and also an imitator of Léonard da

Vinci. He lived long at Bergamo and was generally con-

sidered a native of that place. ' but,' says Lenz, ' we are

deluded to Sig. G. Beltramanni for showing, in a work published
in 1600, that Loto was a native of Venice? he found him
thus noticed in a public contract, ' M. Laurentius Lottus de

Venetia nunc habitator Bergamii'—Master Lorenzo Loto,
of Venice, now a resident of Bergamo. Loto lived also some
time at Treviso, at Recanati, and at Loretto, where he
died. His works range from 1518 to 1554. Lanti ventures

an opinion that Loto's best works were perhaps those

written by Raphael or by Correggio, if treating the same

subject. His masterpieces are the Madonnas of S. Bartolomeo,
and Santo Spirito, at Bergamo.

Pittori, &c.; Tassi, Gerga, &c.; Lanni, Storia Pittorica, &c.

LOVAT, LORD. Simon Fraser, afterwards Lord Lovat,

was born in 1806, at Beaumont near Inverness, in Scotland.

He belonged to a distinguished family of the Fraser clan as
early as the reign of Malcolm IV. about 1158, and

who had large possessions in Tweeddale and elsewhere in the

south of Scotland. Since Simon Fraser's fat of something infi-

in every year. After receiving the usual instruction at a

grammar-school, he was sent to the University of Aberdeen,
Loudon, John Claudius, was born at Cambuslang, in Lanarkshire, on the 8th of April, 1783, where his mother's only son was the Rev. Dr. Claudius Buchanan, author of 'Christian Researches in Asia,' then resided. His father was a farmer, and lived at Kersel Hall, near Gogar, about five miles from Edinburgh. As a child, Loudon exhibited an extraordinary delight in the sight of a garden, and a readiness to doze in the arms of his nurse, if not actually fast asleep, the sight of a pleasure was in nailing walks and beds in a little garden his father had given him. He was early sent to reside with an uncle at Edinburgh, where the boy was strongly recommended for education, and here he attended a public school, and also the classes on botany and chemistry. In addition to the Latin he learned at school, he obtained a knowledge of French and Italian, and paid his masters the compliment of understanding among the traditions from these languages, which he sold. At the age of fourteen he was placed with a nurseryman and landscape gardener, and continued his attendance on the classes of botany and chemistry, and to the added agriculture, in the university of Edinburgh. During this period he acquired the habit of sitting up two nights each week for the purpose of study, a habit which he continued for many years.

In the year 1809 Loudon first came to London, and as he brought good recommendations from Edinburgh, he found no difficulty in getting employment in his profession of a landscape gardener. One of his earliest literary efforts was made this year in the form of a paper contributed to the 'Literary Journal,' entitled 'Observations on laying out the Public Squares of London.' It was the practice when this article was published, to adorn the squares of London with a very sombre vegetation, and Loudon was one of the first to introduce plants. This practice the author strongly condemned, and recommended the lighter trees, as the oriental plane, the sycamore, the alder, and others, which are now generally cultivated, and add greatly to the beauty of London squares. In 1804 he returned to Scotland, and in the same year he published his first work, entitled 'Observations on the Formation and Management of Useful and Ornamental Plantations,' 8vo., London. He returned to England in 1806, and published a small work, entitled 'A short Treatise on Some Improvements lately made in Hothouses,' 8vo., Edinburgh. In 1806 he published his 'Treatise on the Management of Country Residences, and on the choice of situations appropriate to every class of Purchasers,' 8vo., London. This work was illustrated with thirty-two copper-plate engravings of landscape scenery drawn by the author.

In 1806 an accident turned his attention to farming. Travelling one night on the outside of a coach, exposed to the rain, and neglecting to change his clothes, he became attacked with rheumatic fever, which left him so debilitated that for the sake of his health he took lodgings at Pinmer near Harrow. Here he had an opportunity of observing the inferior farming then practised in England, and persuaded his mother, who was joint-proprietor of the estate, with which she was conjointly with his father, they rented Wood Hall, and such was their success that the following year Loudon wrote a pamphlet entitled 'An immediate and effectual Mode of raising the Rent of the Landed Property,' 8vo., London. Published by a Scotch Farmer, now farming in Middlesex. This led to his introduction to General Stratton, the owner of Tew Park in Oxfordshire, and his undertaking the management of this estate as a tenant. Here he established a kind of agricultural college, in which he engaged to teach young men the principles of farming; and in 1809 he wrote a pamphlet on the subject entitled 'The Utility of Agricultural Knowledge to the Sons of the Landed Proprietors of Great Britain, &c., by a Scotch Farmer and Land-Agent.' He carried on his farming so successfully that in 1812 he found himself worth 15,000l., and being more anxious for the cultivation of his mind than for the pursuit of wealth, he determined to give up his farm and travel on the Continent. He left England in March, 1813, and after visiting the principal cities of Germany and Russia, and accompanying the Emperor with his pen and pencil all that he found worthy of notice in his own profession, he returned to his own country in 1814. On his return to London, finding that the chief part of his capital had been lost through unfortunate investments, he devoted himself with renewed energy to his old profession of landscape-gardening.

He now determined to publish a large work on the subject of gardening; and in order to complete his knowledge of ornamental gardens, for the purpose of rendering his work more valuable, he visited France and Italy in the year 1819. In the year 1822 appeared his great work, 'The Encyclopædia...
of Gardening," which contained not only a vast amount of original and valuable matter on every department of horticulture, but was copiously illustrated with woodcuts in the text. This work had a very extraordinary sale, and fully established the reputation of the author as one of the most learned and able horticulturists of his day. A second edition was published in 1824. The success of this work led him to engage in another equally laborious and extensive, and on the same plan, as "Collections of Gardeners' Specimens," of which the second volume was published in 1826, with the title "Encyclopædia of Agriculture." Another work, though not exactly on the same plan, but similar in design and comprehensiveness, was edited by him, and published in 1825. This was the "Encyclopædia of Cottage, Farm, and Villa Architecture," which was all his own labour. The labour," says Mrs. Loudon, "that attended this work was immense; and for several months he and I used to sit up the greater part of every night, never having more than four hours' sleep, and drinking strong coffee to keep ourselves awake." This book was published in 1832, and was very successful. He then planned a work of still greater extent, which demanded more time than any of the preceding: this was his "Arboretum et Fruticetum Britannicum," comprehending an account, with engravings, of all the trees and shrubs growing wild or cultivated in Great Britain. This work was brought out in three volumes, and, with the preceding, was published at his own expense. After paying artists and other persons engaged in the work, "he found at its conclusion that he owed ten thousand pounds to the subscriber, the engraver, and that he had been employed." The sale of this work was slow, and seemed to have involved him in pecuniary difficulties, which, although they did not abate his energy, still preyed upon his mind, and hastened his death.

During the time that these works were going on he edited several periodicals. In 1826 he established the "Gardener's Magazine," which he carried on till his death. In 1828 he commenced the "Gardener's Chronicle," which was issued until 1836, when it passed into other hands. In 1834 he started the "Architectural Magazine," which he gave up in 1836. In 1836 he commenced the "Suburban Gardener," a monthly publication; so that he had four monthly works, in addition to the "Arboretum," going on at the same time.

These labours would appear very extraordinary for a man in perfect health and with the use of his limbs, but they become more extraordinary when the circumstances are known under which he wrote them. His first attack of rheumatic fever, in 1806, was so severe as to produce permanent ankylosis of his left knee. Subsequently his right arm became affected, and the years that followed were full of trysmal remissions. In 1824 his arm was induced to submit to shampoing, during which process his arm was broken so close to the shoulder as to render it impossible to have it set in the usual manner; and on a subsequent occasion of this kind in 1825, it was thought necessary, in 1826, to have recourse to amputation. In the meantime his left hand became affected so that he could use only the third and little finger. After this period he was obliged to employ for all his works both an amanuensis and a draftsman. With this infirm and maimed body, his mind retained its vigour to the last. Early in 1843 he was attacked with chronic inflammation in his lungs, which terminated his existence on the 14th of December of that year. He continued working till the day of his death, and "died standing on his feet." The literary men have attempted or executed so much as Loudon, and that under circumstances of the most depressing and afflictive nature. The tendency of his mind was essentially practical, and in this will be found the cause of the success of all his writings. In his work of gardening he displays great anxiety for the mental improvement and welfare of the class of men who make this their occupation; and the book on which he was employed at the time of his death is entitled "Self-Instruction for Young Gardener." In all his works he never lost the opportunity of pointing out the bearing of his subject on the moral and social improvement of his fellow-creatures.

The "Gardener's Magazine," in its first number, 1826, has a notice of a daughter. Mrs. Loudon is the authoress of "The Mummy; 'Ladies Flower Garden;' 'Ladies Botany,' etc. The materials for this notice have been chiefly collected from a Memoir by Mrs. Loudon in "Self-Instruction for Young Gardeners." A complete list of Loudon's works is given in the 'Proceedings of the Linnean Society' for 1844.
Lowell Statistics, January 1, 1845.

Capital stock ........................... $10,850,000
Number of mills, exclusive of print-
works, &c. .................................. 38
Spindles ................................... 204,076
Looms .................................... 6,304
Females employed ........................ 6,320
Males employed ........................... 2,415
Yards made per week ....................... 1,493,100
Bales of cotton used in ditto ............ 1,175
Pounds of cotton wrought in ditto ...... 464,000
Yards dried and printed ditto ......... 287,000
Tons of anthracite or per annum ....... 12,000
Cords of wood per annum ............... 3,270
Gallons of oil per annum ............... 64,842
Flour for saws, barrels, per annum ........ 4,000
Charcoal, bushel per annum ............. 69,000
Yards of cloth per annum ............... 75,873,200
Pounds of cotton consumed ............. 24,128,000

A pound of cotton averages 31.5 yards; 100 lbs. of cotton
will produce 89 yards of cloth. Average wages of females,
dear of board, per week, $1.75 dollar. Average wages of
males, clear of board, per day, 70 cents. Average amount of
wages paid per month, 138,500 dollars.

Lowell, as it was and as it is, by the Rev. Henry A.
Miles, 1860., Lowell, 1845.; Americans Almanac, 1846;
Knight's Weekly Volume, vol. ii.)

LOXONEMA. A group of spiral Gasteropoda is thus
named by Phillips. The species occur in Silurian, Devonian,
and carboniferous strata. (Pulmonata Forst. of Devonshire.)
LOYOLA, IGNATIIUS, Don Illego Lopez de Recalle,
more generally known under the name of Loyola, was the
youngest child of Don Bertram, lord of Oneya and Loyola,
a nobleman of high birth and distinction in his province, and
of the family of Herrn Schi de Dali. He was born in the year 1491, at the
castle of Loyola, in that part of Spanish Biscay afterwards
called the province of Guipuzcoa. In early youth he was
attached to the court of Ferdinand and Isabella, in the quality
of a page; but the vivacity of his dissmetatião suited him
for a situation so devoid of excitement, while the recital of
the noble deeds of the Spanish knights, who had lately freed
their country from the yoke of the infidels, rendered him desirous
of emulating their heroism. His father, when the abortive
rebellion of the Basques, in the court of Spain, had placed him under the care of his relation
Don Antonio Marques, duke of Najars. This nobleman,
perceiving the military bias of his young ward, got him
instructed in the art of war, and afterwards received him in his
suit. The ardent imagination of Ignatius was in the meanwhile kept in constant excitement by the eager perusal of the various romances in which were idealized the religious spirit of Spanish chivalry; to this was added the example of his brother, who, following with delight the profession of arms. After joining the army he soon rendered himself conspicuous by his gallant bravery on every occasion; his conduct, in other respects, is described as having partaken in all the qualities generally incident to a useful life; one vice, however, that of gambling, he appears constantly to have avoided.

He was in his thirtieth year when he assisted in the defence of Pampeluna, against the French; in the assault he was wounded and his right leg had been fractured by a cannon ball, and his left, at the same time, injured by a splinter. The French, into whose bands he had fallen prisoner, respecting his misfortune and admiring his bravery, had him conveyed to the castle of Loyola, which was situated at a small distance from Pampeluna. A long and painful confinement was the result of his wounds, and a cruel operation was resorted to, which, though endured with characteristic courage, reduced him to the last extremity. His recovery from the effects of the operation, though he saw in it a miracle, appears to have produced no change of conduct. A second operation, however, became necessary, owing to the inconvenience which had resulted from the first, and the consequences entailed a longer and more tedious confinement. To relieve his weariness he requested to be provided with those records of ancient chivalry which had been the delight of his leisure time, but instead of being furnished with works of mystic devotion and the lives of saints. Of a disposition naturally visionary and romantic, deprived of the means of pursuing a career in which he hoped to attain the highest distinction, the attentive perusal of the zeal and suffering of holy men infused in his mind an ardent desire to imitate them. As he eagerly pondered over the recital of the actions of St. Dominick, or of St. Francis, he was wont to say to himself was prevented him from imitating their deeds? But often were these heavenly aspirations clouded by the intervention of worldly thoughts and of temporal affairs. At other times, when in this spiritual combat the insatiable desire of a mystic vocation or an acute imagination would portray to him visions of celestial glory, in that hour of struggle, encouraged and inspired him. He has graphically described the various scenes through which he passed in his introduction to a religious life, in his 'Spiritual Exercises,' the origin of which may be referred to the same time as his first awakening from worldly alimony. This remarkable work is not a book of doctrine, it is the description, to use his own words, of the longings of soul seeking to be appeased, not by much knowledge, but by the scene and relish of inward things. He first minutely details a variety of rules for the guidance of spiritual life; he then expounds the sacred history, and frequently gives a fanciful interpretation; he afterwards gives an allegorical representation of the convert's progress from the primitive state to the realms of celestial bliss. Loyola but detailed his own feelings and actions in this extraordinary life. From this time all his desires were directed to one great object, an entire devotion to the service of God. For this purpose, renouncing worldly pursuits, he took himself from the paternal home, from his kindred, and from his friends. Regardless of the kindly opposition of his eldest brother, become by the death of his father he head of the house of Loyola, he resolved upon retiring to a Benedictine monastery at Mount Serrat, in order to prepare himself for a pilgrimage to the Holy Land. He became acquainted in that monastery with one of the brothers named John Chamoues, of high reputation for his piety and zeal, who was anxious to unfold to him the confession of his former sins and the confidences of his religious aspirations. While journeying towards Mount Serrat, he arrived at a village at the base of the hill on which the monastery stood, and which he thought to be the

pilgrimage, in order that this severe penance might excite in his mind a deeper remorse for sin. On leaving Mount Serrat, he directed his steps towards Manresa, a small town within three leagues of this monastery. There he repaired to the hospital in which he had found shelter for the poor and sick, imposed upon himself a series of new and severe penances. His deeds of charity soon acquired for him celebrity in that town, and, though clad in the rags of destitution, he was unable to walk the streets without an important admittance of the multitude. To avoid the temptation of vain glory, he retired to a cavern hollowed in a rock at a short distance from Manresa, where he redoubled the severity of his penances, his hours of solitary meditation, and his alternate fasts of inanimate exhaustion at the door of his cell, and was borne back to the Dominican hospital. On his recovery, his mind, weakened by mortifications and fastings, fell into a state of spiritual despondency. His doubts and despair, his fears and temptations, are described with edifying minuteness in his own writings and by his early historians. It does not appear that any particular doctrine had made an impression on the mind of Loyola, as that of justification by faith alone, had made on that of Luther. He lived, as it were, within himself, and his emotions were actuated by the alternate inspirations of good and evil; he had taught us in his 'Spiritual Exercises' the method of informing the soul of its own weaknesses and the soul being gladdened by the one and depressed by the other. One day, at length, he awakened as from a dream, his imagination had portrayed to his mind the visible representation of heaven and hell. When he was in the midst of this vision, he poured down the blessings vouchsafed to him, and, refreshed in spirit, he arose a new and a mightier man.

After residing ten months at Manresa, he left that town for Barcelona, in order to return to Rome. In that city he remained a few days, in order to obtain the blessing of the Pope Adrian VI. upon his enterprise; he then resumed his journey, passing through Padua and Venice, travelling alone and on foot, farther and farther from his native land. His voyage from Venice to Cyprus presented a fresh trial for his patience and constancy, his pious efforts for the conversion of the crew of the vessel in which he sailed being met by a most unmerited and even hostile reception from the people, with some pilgrims for the Holy Land, and reached Jerusalem on 4th September, 1523. He there visited with holy veneration the hallowed spots which religious tradition has consecrated. To accomplish the objects of his journey, he was deaasional not only of contributing to the edification of the believers, but also to the conversion of the infidels. His projects, however, were defeated by the refusal of a concession of residence from the primates of the Church at Rome. He then re-embarked for Europe, and arrived at Venice in January, 1524, and from thence he returned to Barcelona. In this town he determined upon making some new arrangements, and, on the 2nd of January, 1524, he was present at the Council of Trent, where the conversion of souls. He addressed himself for that purpose to Jerome Ardelela, while a pious lady, Isabella Itzel, undertook to provide him with the necessary means. His career for educational reform was in a primary negligence. A camp had obliteraied from his mind the little he had learnt. At the age of thirty-three, he began with zeal to industry to apply himself to the rudiments of grammar. But his active mind found extreme difficulty in applying itself to its tedious minutiae; and absorbed in religious contemplation, each word he met with excited a train of pious thoughts. Still by constant application he appears to have made some progress in learning. He continued at Barcelona till the zealous attempts on his part to reform some irregularities which existed in a convent of nuns exposed him to the vengeance of those who had been the cause of his removal. He returned to the University of Alcalá, which had lately been founded by Cardinal Ximenes, in order to prosecute his studies. A religious address which he delivered to the students was the occasion of his being dismissed; but University reform and theology during four years, before he could again be permitted to teach in public, was imposed upon him. In 1527 he retired to Salamanca, where, having imprudently resumed his public exercise, he was again punished by the condemnation of the Inquisition, and dismissed him from his city with a similar injunction.

Discouraged by the rude reception which his pious labours had met with, and weary of his native country, he determined that time the most renowned seat of learning in Europe. He arrived in February, 1528. The slender means which had been provided for him by the charitable generosity of his
friends were published by the dishonesty of a fellow-student, and he was again compelled to have recourse to begging for his subsistence. He, however, zealously applied himself to the studies of the University: obliged to recommence his rules of grammar and the principles of philosophy before he could be admitted as a theological student, he buried himself in the class of the youngest and least advanced scholars, and besought their teacher to treat him as one of them. His time in Paris appears to have been spent partly in laborious acquiring the knowledge of a degree, and partly in the endeavours to obtain a salutary influence over his companions. In the latter pursuit he was eminently successful. Two students shared his rooms, Peter Faber (called Le Fève in Art. Januar.), a man of singular manners, and Francis Xavier of Navarre, of noble ancestry and aristocratic demeanour. These young men, of such different dispositions and habits, were the first-fruits of Loyola's labours. From that time the three companions formed the closest intimacy, dividing their gains, and sharing each other's toils. Shortly after three more students acknowledged the influence of Loyola, and joined his small society: their names are recorded in the article Jasovra, F. C. On 15th August, 1534, they assembled together at the Church of Montmartre, in one of whose subterraneous chapels Faber, who was a prior, admitted to this noble society the two companions. They then took the solemn vows of chastity, absolute poverty, devotion to the care of Christians, and to the conversion of infidels. They further resolved on proceeding to Jerusalem, but in case this project should be put in their way, they decided upon placing themselves under the guidance of the Pope, and implicitly submitting to his directions. Such was the humble origin of the Society of Jesus, and in all ages, those three companions have placed themselves under the banners of Jesus, as soldiers under their chief. The history of the founder now becomes mingled with that of the Order itself. Its early progress, the opposition it encountered, the unity of its purposes and the rules and constitutions by which it is governed, are fully and clearly detailed in another part of this Cyclopaedia. [Jasovra, F. C.] We will only, therefore, briefly state the principal events in Loyola's life which are not alluded to in that article.

After revisiting his native country, where he religiously repaired the effects of some early faults, he proceeded to Venice, in which city he was joined by his companions, and from thence proceeded to Rome. Their intended departure for Palestine was interrupted by the war which broke out, in 1537, between the Venetians and the Turks; they therefore presented the offer of their services to the See of Rome. They were gratefully accepted by the reigning pontiff, who gladly availed himself of the support of a society of men full of zeal and enthusiasm, and bound together by the common tie of implicit obedience. In consequence of the open schism and lurking disaffection, the Church of Rome found an unexpected source of strength in her own bosom, a source enriched by the conversion of Ignatius Loyola (Iallam). On the 27th September, 1540, Paul III. published a bull sanctioning, under some limitations, the establishment of the Order; another was finally issued in 1543, which removed those limitations, and made the sanction unconditional. Meanwhile six of the oldest members met together to elect a president subject to no control but that of the See of Rome; their choice fell on Loyola. He remained at Rome as the centre from which he was to control and direct the movements of the Society. His time was spent there in revising its rules and constitutions, and in works of charity. He founded an asylum for the protection of Jews who had become Christians, which was called the asylum of Girona, to be founded at Gandia in Spain; the statutes were drawn up by Loyola, and the same privileges were accorded to it which belonged to the universities of Alcala and Salamanca. Not twenty years had elapsed since Ignatius left Loyola, when a poor and despised student, had been consecutively expelled as a factious and illiberal pretender. On the 31st July, 1556, this extraordinary man, worn down by wounds and sickness, was left in the world which for so many years he had looked upon only as the scene of charitable labours. It was a useless task to attempt a delineation of Loyola's character; it is best known by his works. Whatever differences of opinion may be entertained respecting the order of the Jesuits, there can be but little respecting their founder.

The memory of Ignatius was consecrated by a ceremony known in the Church of Rome by the name of Beatification, performed by Pope Gregory XVI. in 1842. His festival is celebrated on the 31st July.

His life has been written by Gonzales and Rhaddincz, a man of his early companions, the latter his friend, and by Maffes in Latin, Bertiy and Bonhans in French. His 'Spiritual Exercises' were published at Rome in 1548, and have been translated into French by Drouet de Maupertuis and Clément. His 'Maxims' were translated published at Paris in the year 1638.

An elegantly written sketch of the life of Ignatius Loyola is contained in 'The Portrait Gallery' published by Knight, vol. vii. By a misprint in this sketch of Knight's, his death is made to take place in 1566. Further information respecting him may be obtained in Ranke's 'History of the Popes,' vol. i. p. 181-200 of Miss Austin's translation; Allan Butler's 'Lives of the Saints,' Fabre's 'Continuation of Fleuray,' vol. xxvi.; De Tho, 'Hist. Universello,' vol. iii.; and Bayle, 'Dict. Historique.' Bayle is chiefly useful in correcting some errors of preceding writers; but the whole is written in a cold and sarcastic manner.

LUC'A-NIDJE, the family of Stag-beetles, a name popularly applied to these insects on account of the very large and powerful mandibles with which the males are furnished. They are a genus of Insecta, and appear to have been already known to the ancients. Their mandibles are prolonged to the entire length of the body, and in the Lecanus curvus of our own country are very formidable instruments of offence. They live in the day in the trunks of trees and old wood, and take flight at the approach of a man. The Four O'clock, or the Ox-eye have numerous to the males, which fight with great ferocity among themselves for possession of their mates. The larvae, which is supposed to have been the animal called Cosmos by the Romans, and esteemed as a delicacy by them is a poisonous insect. When full-grown it forms a cocoon of the dust of wood which it has ground down by its powerful jaws, and after remaining some time as a pupa it undergoes its final transformation to pass over the visible portion of its life as a perfect insect. Some of the foreign genera of Stag-beetles are remarkable for their brilliant colouring. In Britain we have four species which belong to as many genera. (See Westwood's 'Introduction to the Modern Classification of Insects,' vol. i., and the writings of Macleay, Kirby, Roesel, and Hope.)

LUCERNAL MICROSCOPE. This is a hollow pyramidal box, of wood, at the smallest extremity of which is a tube carrying the usual system of lenses for magnifying objects. At the larger end, which is towards the observer, there are two lenses in whose axles, and the smaller of which is at the small lenses at the opposite extremity, being coincident with the axis of the box; and between the exterior of the two lenses the eye of the observer is placed, who by means of a perforated card, or a piece of paper, or a small frame as usual, and is placed in a grooved made for the purpose immediately beyond the tube containing the system of lenses, at the small end of the pyramidal box.

This box, the axis of which is in a horizontal position, is mounted on a brass stand, which may be placed on the floor, on a table, and the parts of the apparatus are capable of being correctly adjusted by means of screws. The instrument was invented by Mr. George Adams, a distinguished optician in London, and first described in 1786. He intended his microscope objects being projected on the ground-glass screen by the rays of light transmitted from a lamp through the lenses, the observations being made by night or in a darkened room.

The correct use of the instrument consists in fixing the achromatic of the lenses at the object end of the instrument, a subject which has been treated in the article Microscope, P. C.; and therefore it will be sufficient to notice here only the means employed to enlighten the field of view.

For this purpose, in general, an Argand lamp is placed beyond the object, with respect to the microscope; or, if thought necessary, two or more such lamps may be so situated that the light, which illuminates the object, is, when an opaque object is to be viewed, made to fall in a convergent state upon a small concave mirror, which is so inclined as to reflect the light back upon the object; and
from the different points of the surface of the latter the pencils of rays proceed through the object-lenses and the box to the glass screen.

By the refraction of the light in passing through the lenses a highly magnified image of the object is formed; and several phenomena may be detected by this light as it falls back on the screen at the same time; or, by placing the eye at a small aperture in the produced axis of the instrument, one person may, with a pencil, draw on the glass, or on this, the rays of light being reflected from the object; it being understood that, by means of the proper adjusting-screws, the rays in each pencil are made to unite accurately in one point on the screen.

This image being viewed to be transparent, the light is made to fall in a condensed state upon it, after having been transmitted through a convex lens, or two such; and, from the object, the rays proceed as before to the screen through the system of lenses which constitute the compound objec-
glass of the microscope, and through those at the opposite extremity of the box.

Instead of having a plate of ground-glass to receive the image, the pencils of light from the object, after passing through the lenses, may be allowed to fall on a board painted white or covered with white paper; the distance of the board from the instrument (about 12 feet), being such that the light, on each pencil may converge to a point at it: thus there will be obtained a greatly magnified image of the object, which may be observed by many spectators at one time. It would have the same segment of the hollow sphere, the light being received on its concave surface; for by that construction the image will be nearly equally distinct at the centre and about the margin.

Such an image, which was described by Dr. Lieberkühn in 1738, produces a greatly magnified image of a small object in a similar manner by means of the sun's light. It consists of a concave tube fixed by its base to a frame of wood; the latter being screwed to a closed window-shutter at an aperture purposely made in the latter: the tube pro-
jects into the room, which, when the observations are to be made, is rendered quite dark, and is sometimes lined with black solar microspherically reflected by a system of lenses contained in the tube, as in other microscopes. On the exterior of the window is a frame carrying a rectangular piece of looking-glass; this frame is attached by a joint at one of its sides to a ring of wood or brass which is made to surround the aperture in the shutter. The mirror, by turn-
ing on the hinge, is capable of being fixed at any angle with the wall of the building; while the ring to which it is at-
tached can, by means of a rack and pinion, be made to turn on the horizontal axis of the instrument, so as to permit the rays of the sun, whatever be the position of the latter, to be reflected into the tube. By means of lenses disposed for the purpose, he made to converge light proceeding from thence, after refraction through the system of object-
glasses, they proceed to a screen on which they depict the magnified image.

When the object is transparent, the rays of solar light are allowed to pass from the mirror directly through the lenses to the screen; but when it is opaque, a convex lens placed at the aperture in the window-shutter causes the solar rays to condense on a small mirror placed in a box at that end of the instrument which is within the room, and from this mirror the rays are reflected to the object. The condensed light thus thrown on the object diverges from thence and passes through the system of lenses, by refraction in which the magnifying power is produced; these lenses being placed in a tube which, as well as the object, is within the box contain-
ing the mirror last mentioned, but a little above the lat-	ter, the rays of light proceeding from the object to the magnifying lenses may not be intercepted.

The mirror by which the sun's light is reflected into the instrument is sometimes connected with a clock-work apparatus, by which its position is continually varied correspond-
tly to the apparent change of the sun's place; and thus the reflected light is made constantly to pass through the tube which passes itself through the coronas.

Sir David Brewster has given, in his 'Treatise on New Philosophical Instruments,' p. 405, &c., a method of preparing objects of natural history for observation by the micro-
scope, which may produce in the image an almost perfect shape and colour, and thus be seen to be the greatest advantage.

The solar microscope will, probably, never be generally employed, on account of the necessity which it involves of having an apartment particularly situated, and of being used only when the sun shines. The lucernar microscope can, of course, be employed at any time; and if, for an Argand lamp, the oxy-hydrogen light be substituted, the lenses also being achromatic, the image will be distinct and correctly defined.

Microscopes of the same principle have been applied to the study of flowers, feathers, bony, mammary, and other microscopic objects without abdomen. The species are trees, yielding a milky juice, with scattered entire coruscous leaves, and 1-flowered axillary or latorial peduncles.

L. Mammosa, the Common or Mammee Sapota, has oblong lanceolate, oblong cuneate, glabrous leaves, with solitary flowers. This plant grows from fifty to one hundred feet in height. It is a native of the southern parts of South America, and of many of the West India Islands, where it is also cultivated. The fruit of this tree is eaten in the West Indies. It is of a large size, oval-shaped, and covered with a brownish rough skin, under which is a soft, white, subacid, very aromatic, and which, on account of its flavour, is called Natural Marmalade. P. Browne calls a variety of this tree Bully-
tree, because it grows the tallest of all the trees in the woods of Jamaica.

Several other species of this genus have been described. They are all natives of various districts of South America, and yield edible fruits similar to the preceding species. They were at one time ranked with the genus Asimia, the species of which also yield edible fruits.

(ACHRAS, P. C.)

(Don, Gardener's Dictionary.)

LOUGI, ANDRE'A DJ, commonly called L'Ingegno, and sometimes Andrea di L'Ingegno, was born at Assisi about the middle of the fifteenth century.

The common story of this painter, originating with Vasari, has been completely overthrown by Remondino in his 'Italianische Forschungen,' where the table of facts points out how, in the present century, it has been invariably followed by all subsequent writers on the subject, down to the time of Rummoh, that L'Ingegno was the rival of Raphael in the school of Pietro Perugino, that he became suddenly blind while assisting his master Perugino in the Sistine Chapel; and that the then pope, Sixtus IV., granted the unfortunate painter a pension for life, which he enjoyed until his eighty-sixth year. Rummoh has shown this account to be, with one exception, wholly incorrect; the only possible part of it is that L'Ingegno assisted Perugino in the Vatican; this he may have done, as he was his assistant in some works in the Cambio, or Exchange, of Perugia.

L'Ingegno was the fellow-pupil with Perugino, for he painted only one year after the birth of Raph-
ello, in 1484, a coat of arms for the town-bull of Assisi, where he was then an established master. He also, long after the death of his master, held official positions, and can never doubt of his retaining his sight. In 1505 he was procurator; in 1507, arbitrator; in 1510, syndic syndi-
ciator potestatis; and in 1511 he was appointed by Julius II. papal treasurer at Assisi—Canemarius Apostolicus in Civitate Assisi. L'Ingegno, therefore, instead of receiving a pension from Sixtus IV., received a salary from Julius II., 27 years after the death of Sixtus, who died in 1484. From these several appointments he had probably given up painting, which may have been either owing to weakness of sight or from greater advantages to be had elsewhere: his brother was one of the canons of the cathedral of Perugia.

The only certainly known work by L'Ingegno is the coat of arms already mentioned. The prophets and sibyls in the Cambio at Perugia are assigned to him, but it is quite uncertain what portion of these works he has executed by his own hand: the prophets and sibyls also in the Basilica of Assisi were attributed to him, but it has been shown that they were executed in the sixteenth century by Adone Dole. There are further attributed to L'Ingegno two sculptures of the works at Bolsena, and a Holy Family in the Louvre, a beautiful small work in the style of Perugia. Rumohr conjectures, from the style of L'Ingegno in these works attributed to him, that he was the pupil or prentice of Domenico Marmolada. He seems to have been more for a general aptness for business, than for any particular skill in painting.

(Vasari, Vite de' Pittori, &c.; Lami, Storia Pittorica, &c.;
LUNACY. [Insanity, P. C.; Lunacy, P. C.] Some recent acts have made alterations in the proceedings under commissions of lunacy.

An act of the 3 & 4 Wm. IV. c. 36, is entitled 'An Act to diminish the Inconveniences and Expenses of Commissions in the Nature of Writs Do Lunatico Inquirendo; and to provide for the Better Care and Treatment of Idiots, Lunatics, and Persons of Unsound Mind, found such by Inquisition.'

An act of the 5 & 6 Vict. c. 84, is entitled 'An Act to alter and amend the Practice and Course of Proceeding under Commissions in the Nature of Writs Do Lunatico Inquirendo. The first section empowers the Lord Chancellor to appoint two serjeants or barristers-at-law, to be called 'The Commissioners in Lunacy:' and enacts that in future all Commissions in the nature of Writs Do Lunatico Inquirendo shall be directed to such commissioners, and that such commissioners shall hear and decide all cases in which courts of chancery, admiralty, and probate have execution, and in such manner as the Lord Chancellor shall from time to time direct; and it is provided that nothing in this act shall prevent the Chancellor from issuing any commission in the nature of a writ De Lunatico Inquirendo, addressed to any fit or proper person or persons, in addition to the Commissioners in Lunacy.

§ 3 empowers the Chancellor to refer to the Commissioners in Lunacy, or either of them, any of the inquiries and matters connected with the persons and estates of Lunatics which are usually referred to the Masters in Ordinary in Chancery; and § 4 makes the Commissioners in Lunacy visitors, under the direction of the Chancellor, of all persons found idiot, lunatic, or of unsound mind, by inquisition, jointly with the three visitors appointed by the 3 & 4 Wm. IV. c. 36.

§ 7 empowers the Chancellor from time to time to regulate the form and mode of proceeding before and by the said commissioners, and the practice in matters in Lunacy; and to regulate the number of jurors to be sworn to try inquests on persons who are directed to be dealt with under the acts De Lunatico Inquirendo; but it is provided that every inquisition on such commission shall be found by the oaths of twelve men.

By the 8 & 9 Vict. c. 100, § 2, the two commissioners of the Lunacy are henceforth called Masters in Lunacy, and take the same rank and precedence as the masters in ordinary of the High Court of Chancery. Some other regulations as to the duties of the masters in lunacy are contained in 8 & 9 Vict. c. 100, §§ 95-99.

The other sections of the act 5 & 6 Vict. c. 84, make regulations as to fees and other matters, for which the act must be consulted. The salary of the commissioners is 2000l. a-year, free from all taxes or abatements.

The term Lunatic is only properly applied to a person who is found to be a lunatic by the verdict of a jury under an inquisition, as explained in Lunacy, P. C. But the term lunatic is also applied to any person who is convicted of being committed in lunatic asylums or hospitals, under such regulations as the 8 & 9 Vict. c. 100, §§ 44-49 prescribe, without having been found lunatic under an inquisition; and also to any single patient who is boarded or lodged for pay at a lunatic in a house not licensed under the act, § 90; and also to any person who is under the care of any person who receives or takes the charge of such one lunatic only, and derives no profit from the charge (§ 111). The above regulations govern all so-called lunatics, who have not been found lunatic by a jury, the 8 & 9 Vict. c. 100, § 94. Conclusively, That whenever the commissioners in lunacy shall have taken any charge of the property of any person declared or taken charge of as lunatic, that charge is not duly protected, or that the income thereof is not duly applied for his maintenance, such commissioners shall make such inquiries relative thereto as they shall think proper, and

LUMBRICARIA, a genus of fossil Annulida, from the Silurian strata of Tyrone. (Portlock.)

LUNACY.
report them to the lord chancellor. § 98 enacts, That when any person shall have been received or taken charge of as a lunatic upon an order and certificate, or an order and certifi-
cate under the provisions of that act, and shall either have been discharged or declared insane for the twelve months next past, or shall have been the subject of a report by the commissioners in lunacy in pursuance of § 94, the lord chancellor shall direct one of the masters in lunacy to inquire and report to him as to the condition of the person described in the certificate, and such certificate is authorised to make orders for the appointment of a guardian or otherwise for the protection, care, and management of such lunatic, and such guardian is to share the same powers and authorities with an executor of the person: and a lunatic found by such inquisition now has, and to appoint a receiver or otherwise for the care and management of the estate of such lunatic, and such receiver is to have the same powers as a receiver of the estate of a lunatic found by such inquisition now has; and the chancellor is also empowered to make orders for the application of the income of the lunatic towards his maintenance, and the cost of the care and management of his person and estate, and also as to the investment or other application for the purpose of accumulation of the surplus; but such protection, care, and management are only to continue so long as such lunatic shall continue to be detained as a lunatic upon such order or certificate as aforesaid, and shall not further time, not exceeding six months, as the chancellor may fix; but the chancellor may in any such case, either before or after directing such inquiry, and whether the master shall have made the inquiry or not, direct a commission to be appointed to inquire into the nature of a writ Do Lunatico Inquirendo to issue, to in-
quire of the lunacy of such person.

In the Roman system, persons of unsound mind (farii) were treated as incapable of making decisions under their own volition. The examination and medical records of every lunatic patient were recorded in the praeiturae. The medical officers were appointed by the secretary to the commission. The commission was to be appointed for the care of the insane. Orders and medical certificates must in future be procured for the care of one patient, similar to those used for the admission of patients into licensed houses; and the maintenance and care of pauper lunatics; and to be 
registered by the secretary to the commissioners. This act only extends to England and Wales, and it does not affect Bethlem Hospital, London. The persons appointed to hold commissions under this act shall be husbands of the commissioners, and are in future to be termed Masters in Lunacy.

The second act, which repeals Geo. III. c. 40, relates to the regulation of lunatic asylums for counties and boroughs, and the maintenance and care of pauper lunatics; and gives to the commissioners a great power over these institutions, which had previously been entirely under the control of justices of the peace. The justices of every county and borough are now the judges who shall determine how far in their respective counties they shall have licences to establish asylums, where none such already exists; and all proposals, agreements, plans, and rules of regulations of each asylum, are to be submitted to the commissioners, and all contracts and esti-
mates approved by the secretary of state. Contracts for the care of insane persons in licensed houses do not exempt any county or borough from the obligation of providing an asylum. Power is given to committees to grant retiring allowances to the officers of asylums; and a medical officer must be resident in every asylum which contains more than 100 patients. Lists of all the patients are to be sent twice, in every year to the secretary of the hospital, at Edinburgh and London. This act extends only to England and Wales, and does not apply to Bethlem Hospital.

Great advantages may fairly be anticipated from the restric-
tions imposed by these acts; and the alteration of the law considering as steps towards the highly desirable result of making all insane persons immediately the care of the State. The duties of the commissioners have, until the last few years, been very imperfectly performed, and the utmost secrecy as to their names and movements was preserved. The management of private asylums must vary considerably, as such houses are rarely built for the purpose, and are frequently under the direction of persons unfitted by their want of education for such an important charge; but these circumstances can by no means be admitted as excuses for the scandalous instances of cruelty and mismanagement which have gone on under the sanction of the State, and which have been the subject of their praise; especially in those large private asylums, where an immense number of paupers are taken at low rates; the temptation held out in such cases to economy at the expense of the comfort and care of the patients, is such as to call forth an especial watchfulness on the part of the commissioners.

The patients who are confined in prisons, hospitals, work-
houses, or in the houses of their relatives, are exposed perhaps more to the danger of cruelty, than the unfortunate who live in their own houses, and are not infrequently treated with great cruelty, even when the intentions of the parties who have charge of them are good, through their entire ignorance of the nature and proper treatment of the insane. The minister, however, has provided for the care of paupers, and for the inspection of private asylums, as well as public institutions.

Management of Public Asylums.—There is considerable diversity in the internal regulations of different public asylums as to the power and position of the medical and non-medical
officers. In some there is a resident physician who holds the supreme authority, and is also steward and general manager; in others the chief officer is the head of the whole establishment; and in others the chief officer is not medical, and the physician is non-resident. The Norfolk asylum was partly founded by a private company, and is so large on paper as to have an English army with a resident medical officer; and it is this fact that has so often been severely commented on by the commissioners in their report.

Under the new act a resident medical officer has been appointed to each asylum, and the whole responsibility of the managers remains with the non-medical superintendent. In the 70th Report of the visiting justices of Hanwell (April, 1844) it is stated that they have appointed an officer in the army to superintend the whole management of the asylum, and that there should be greater order and discipline than had been maintained under medical rule; in the 72nd Report (October, 1844) the resignation of the governor is mentioned, and we cannot learn from the reports that any steps have been taken to appoint a successor, nor whether the advantages derived from his appointment equalled the expectation of the justices.

In all asylums the position of the matron is one that requires to be settled in some uniform manner; owing to the matron having in many cases the wife of the superintendent, an undue importance has been given to her position; the appointment of the female attendants, and even the classification to the injured patients, has been left in her hands. When we consider that the matron cannot possibly have had a medical education, and that in very few cases those who hold the situation possess any previous knowledge of insane cases, it is manifestly improper to allow her too high an authority. In the French asylums, and we believe also in some of those in the United States, there is no matron; a few of the most experienced female attendants act as heads of departments, and receive the orders of the medical officers; and this arrangement, which is found to work exceedingly well at the Salpêtrière, where there are 1500 female patients, seems on the whole to be the best. The effect of placing the matron in a higher position is almost certainly to bring about interference on her part with the duties of the medical officers, which cannot but be of the greatest disadvantage. At Hanwell the salary of the matron is higher than that of the resident medical officers, or than that of any officer excepting the physician.

In the appointment of a chaplain, steward, secretary, accountant, and any other officers, the most important point is to confine their duties within certain proper limits, and to prevent their interference with the patients without the concurrence of the medical officers. If the government should at any time take the entire supervision of asylums for the insane into its own hands, we trust that the mode of proceeding will be to appoint to each asylum one or more superintendents, each one of whom will be entrusted with the entire conduct of the asylum; and to whom, therefore, the power of appointing and dismissing all the subordinate officers shall be given. Uniformity of system, the want of which has been found to exist in each and every institution, is the great defect of the present system, and the careful selection of a competent principal officer responsible for every instance of negligence or cruelty in the asylum under his care, could not fail to improve the general management of these institutions. At Glasgow the whole authority has for some years been in the hands of the resident physician, with the most satisfactory results; and an appointment is made in this plan for Irish and Scottish asylums, where the non-resident principal is the principal officer.

By the acts lately passed, the power which the justices who had the control of different asylums possessed of passing rules at any meeting which entirely changed the system of management, or of summarily dismissing any officer, is done away with. The caprices of the governors of some asylums have changed their entire constitution in a few years.

A great improvement has been made of late years in the class of persons appointed as attendants, or, according to the old phraseology, keepers. That all such persons should possess benevolence and intelligence is essential to the effective working of a properly constituted asylum, and they should be liberally paid. The proportion of attendants to patients in the different English public asylums varies from one to ten, to one to twenty; the former does not seem too much, and is far better than that in the well-managed prisons, where it is however small, should have less than two attendants, in order that it should never be left without one; this is enforced by the rules of several asylums. A large number of attendants renders a vigilant superintendence by night practicable, which is no less important than by day, although it is entirely omitted in some institutions.

Whilst many excellent asylums exist for the rich, and the law is providing an increase of accommodation for the poor, benevolent individuals are now making efforts to secure the benefits of mental reform to the middle classes. It has been suggested to build an asylum in the neighbourhood of London for 300 patients, at a cost of 30,000l., which sum is to be raised by donations and subscriptions. We believe that it will be self-supporting, and it is expected that payments of from 12l. to 1l. 10s. per week for each patient will cover all the expenses. No existing asylum offers to persons able only to pay such a sum the comforts and grace that their position in society has accustomed them.

Construction.—The site and construction of an asylum for the insane are matters of great importance. A healthy and cheerful situation should be the first consideration in an institution intended for the cure of diseased minds. In this respect some existing asylums are very well placed; Hanwell, Lincoln, and Surrey may be instances. Others have been originally on the outskirts of towns, and have been surrounded and built in by the increase of building. The commissioners mention several so placed in proper terms of censure.

It is generally admitted that the building ought not to be smaller than 300 feet square; and the additional asylum for Middlesex is projected to hold 1200. As to plan, no two of the existing asylums are alike, and the most recently erected are by no means the best. In the Surrey asylum a complete circular plan has been most admirably adopted, so that the newest part of Hanwell, in which the bed-rooms face one another, and the galleries are lighted from the top, which renders proper ventilation impossible. To make wide galleries with rooms only on one side would certainly increase the cost of the building; but by introducing a bow or expansion into each gallery, the necessity for a day-room will be done away with. An open area should be left in each of such expansions; it will be a great source of comfort to the patients, and an improvement in the ventilation as well as the general appearance of the gallery; and, with a light wire guard, is perfectly safe. This plan is to be adopted at Hanwell. The chapels should be upwards of 200 feet by 50, and as a ward must occasionally be left with one attendant, there is an advantage in bringing the whole of it within sight from a central position. No ward should contain more than thirty patients; and of those from twenty to twenty-five ought to have single rooms. It is matter of regret to find that dormitories are approved by the commissioners, and supported by the officers of some asylums; they certainly lessen the cost of building, but the quiet and comfort of the institution must be much diminished. Their ventilation is also very difficult; single rooms may be warmed with a hot-water pipe passing along the floor (not over-head), and opening the window for the sake of ventilation will be sufficient for this purpose; but in dormitories it will be difficult to preserve freshness of air with warmth, more especially as the great argument in favour of them is their economy, and an economy partly made by not being responsible for patients' comfort, and partly by having them all in a cubic foot that would be given in a single room. For the sick, the violent, the dirty, and the noisy, single rooms are obviously necessary; and it will, we believe, generally be found that the remaining patients, those whose tranquillity and usefulness entitle them to indulgences, will consider a single room, which they can call their own, one of the greatest that can be given them.

An asylum containing 400 patients may probably be built in a straight line, which is desirable, without the necessity of carrying it higher than the first floor. The chapel and chief officers' rooms, and the rooms used for the worst management of the patients, should form the centre; behind which the kitchen may be conveniently placed, with the laundry on the side next the wards of the women, and the workhouse on that of the men. In the wards branching off from the centre those patients who are quiet and convalescent and the sick should be placed, and the most refractory at the extreme ends of the building, to prevent them from disturbing the others.

Six classes of patients should be made: one, composed of those of which some modification of management will be required:—

1. Tranquil: convalescent and melancholic.
2. Moderately tranquil.
3. Refractory.
4. Sick and intrin.
5. Idiots and other dirty patients.
6. Epileptics of the better class.

These are frequently in
the intervals of their fits the most intelligent of the patients, but during the fits they require great attention.

All the sick, idiots, and epileptics should be on the ground floor, which will be easily arranged, as the tranquil and moderately noisy rooms form the great bulk of the patients, may occupy the upper floor.

To describe the numerous minute particulars to be attended to in constructing and furnishing an asylum is unnecessary here; the great rule should be, that every possible amount of safety should be combined with every possible amount of cheerfulness. There should be the strength of a prison without its gloomy character. No part of the building, whether in work or structure, should be neglected; and scarcely a day passes without improvements being made in one asylum or other—improvements that are worthy of adoption in any to be hereafter built.

An abundant supply of warm and cold water should be secured; or in some cases it will be found that the cost of supplying this necessary article will neutralize the advantages of an otherwise favourable site.

Baths, water-closets, a store-room, and rooms for washing, are essential in every ward. Warm baths are considered by many authorities to be valuable remedial agents, as well as advantageous to the general bodily health.

The commissioners have expressed an opinion that incurable paupers may be accommodated in asylums apart from the curable at a much less expense, and an arrangement for a separate provision for incurables is required by the new act (s. 27) but it cannot be aware that while the incurables comprise all the most tranquil and intelligent of the patients, whose society is of great value to the curables, they also comprehend patients who display every different form of insanity, and require every variety of treatment. It is certainly much to be wished that provision could be immediately made for all insane paupers; but we cannot consider that the removal of all hojje from a large number of them, by immuring them in an 'asylum for incurables,' would be the best mode of attaining this object.

The following is a statement of the cost of building and furnishing twenty-two asylums, including that of the land, which in some cases amounts to a large sum. The mean cost for each patient accommodated is 1542. £2., which is probably more than will be found necessary in most future asylums.

The expense of maintaining patients varies from seven to fourteen shillings per week; this must of course depend in some degree upon the prices of provisions in different parts of the kingdom, and be modified by cheap and dear seasons.

Statistics.—There are in England and Wales 12 county asylums, 4 licensed, and 11 partly charitable, 1 military, 1 naval, and 142 licensed houses; 14 of which last receive paupers. The hospital of Bethlem, which is exempt from the rules that affect other asylums, is here added to this number.

Scotland has eight public asylums; in all of which, we believe, private patients as well as paupers are received; and some are assisted by charitable endowments.

Ireland has twelve public asylums; ten of these are district asylums for the poor; Cork is locally governed, and Swift's Hospital is founded by charter.

Several new asylums are in progress both in England and Ireland.

With a view to present in a few plain statistical tables the results of treatment in each of the existing public asylums, the writer of this article sent blank forms to each superintendent in the kingdom; in almost every case they have been filled up and returned, and their contents are embodied in the following tables. When information could not be obtained in this manner or from reports, the statistical tables published by the Commissioners in Lunacy have been resort to; but these only extend to the end of the year 1843, and required much correction, as they are not upon one uniform plan. We may instance the tables furnished by Bethlem and St. Luke's as containing many of the particulars desired by the Commissioners. In several asylums no average number of patients is given, and the per-centages of deaths and cures are calculated upon other numbers; in other asylums which have been opened many years, the early records are so incomplete as to be useless. In several asylums, even in some cases where the published returns do not contain any distinction of the sexes.

The First Table shows the whole number of patients admitted into the 49 public asylums of the United Kingdom to the latest date to which we can obtain information, 28,537 males, 38,328 females, and 8304 of whom the sex is not specified. Thus the admissions of males exceed those of females by 209, or in the proportion of 1 to 1945; a scarcely appreciable difference. Of the whole number of insane persons in England and Wales on the 1st January, 1844, according to the report of the Commissioners, 1862 were males and 11,031 females; thus the females exceed the males in the proportion of 1 to 984. The greatest mortality among men is the cause of this apparent discrepancy.

The following Table (II.) shows the result in the same asylums as to cures and deaths during the same period. This comparative table is recommended by the Commissioners, in addition to the tables showing the per-centages of cures and deaths on the average number.

The cures are taken as 1.

The term 'Removed' includes all discharged improved or uncured, or escaped.
their comparative immunity from epilepsy and paralysis, which, when combined with insanity, render recovery very nearly if not quite hopeless. It is said also that women more frequently recover from the acute stage of mania, where men die of exhaustion.

The reverse of this apparent rule is found only in the results of some of the smaller asylums, where the deaths of either sex are few. In those returns where the sexes are not distinguished we have reckoned the proportion as equal.

The tables of per-centages of cures and deaths published by the Commissioners have unfortunately not been compiled upon any fixed plan. All computations, excepting upon the average number of patients in the asylum during the specified year, must be fallacious. The following Tables (III., IV.) have been made upon that principle; the blanks indicate the cases in which correct returns are wanting. Some asylums do not publish their average number of patients; others calculate the per-centages of cures and deaths upon the whole number admitted; but this is an entirely delusive method, as these numbers must be continually increasing, while the proportion of patients remaining decreases.

We have, as far as possible, made an average of all the public asylums in Great Britain. The mean number of cures thus appears to be 21:26 per cent., and of deaths 9:92 per cent.; but many asylums depart very widely from this standard. Bethlem, St. Luke's, and their comparative immunity from epilepsy and paralysis, which, when combined with insanity, render recovery very nearly if not quite hopeless. It is said also that women more frequently recover from the acute stage of mania, where men die of exhaustion.

4. Age of first admission.
5. Number probably curable.
6. Number probably incurable.

The registers, to contain all this information, might be of very simple form, far less complicated than those at present in use in several asylums. The sexes should be distinguished in every statement.

Registers should likewise be kept of every instance of restraint, its nature and duration, and of the duration of every seclusion; also of employment and of the value of the work done. Many others might be suggested as useful in various ways, though not strictly necessary for statistical purposes.

**Additions of Personal Exercises.**—No part of the treatment of insanity has of late years excited so much attention as the system adopted in several asylums of totally abolishing the use of all instruments of coercion, which has gained the name of the non-restraining system. We desire to preserve this name, as many asylums, which still continue to use all the ancient instruments of restraint, endeavor by professing to practice the "human system," to lead the readers of their reports to suppose that there is no essential alteration made by the discontinuance of the use of those instruments.

In giving a slight sketch of the progress of this improvement in the mode of treating the insane, we shall consider it as a natural consequence of the progressive amelioration in the management of asylums.

Until the establishment of Bethlem in 1547, we have little or no records of the provision made for the insane; we can only gather that all who were harmless, and many who were dangerous, suspected a miserable existence by wandering and begging; those who could not be permitted to be at large were probably chained in prisons, or in the hands of their friends. Some mention is made of an asylum for insane monks established most at Jerusalem in the sixth century, where all the rigours of monastic discipline were embodied in the treatment.

Even in Bethlem little attention seems to have been paid to the comfort or cure of the patient; the only consideration was the safety of the site and protection of the population. The patients were chiefly naked, and chained to the walls; and were exhibited for money, like wild beasts; and it is even said that the keepers were accustomed to allure to every subject who might appear as more striking objects of wonder to the idle crowd. This shameful practice, by which it appears that an income of 400l. per annum was derived by the hospital, was abolished in 1770; but no improvement was made in any other respect in the treatment of the patients.

The benevolent and courageous Pindol was the first to attempt the restoration of the insane to a position among human beings. The scene of his exertions, which were the first serious attempt at the restraint of madness in the Bethlem hospital for insane men, near Paris. In this frightful prison the universal practice was to load patients with heavy chains,
which remained on for the remainder of their lives, and to
ensure them in dark, unwarmed, and unventilated cells. 
Pinel determined on a once releasing a large number of
patients. The following account of the experiment is
extracted from the 'British and Foreign Medical Review':—
"Towards the end of 1792, Pinel, after having many times
argued the government to allow him to unchain the manacles of
the Bicêtre, but in vain, went himself to the authorities, and
with much earnestness and warmth advocated the removal of
this monstrous abuse. Couthon, a member of the commune,
gave way to M. Pinel's arguments, and agreed to meet him
at the Bicêtre.
Couthon then interrogated those who were
chained, but the abuse he received, and the confused sounds
of cries, vociferations, and clanking of chains in the filthy
and damp cells, made him recoil from Pinel's proposition.
"You may do what you will with them," said he, "but I fear
you will become their victim." Pinel instantly commenced
his undertaking. There were about fifty whom he considered
might without danger to the others be unchained, and he be-
gan by releasing twelve, with the sole precaution of having
previously prepared the same number of strong waistcoats
with long sleeves, which could be tied behind the back if
necessary. The first man on whom the experiment was to be
tried was an English captain, whose history no one knew, as
he had been in chains forty years. He was thought to be
one of the most furious of them; his keepers approached
him with caution, as he had in a fit of fury killed one of
them on the spot with a blow from his manacles. He was chained
more rigorously than any of the others. Pinel entered his
cell unattended, and calmly said to him, "Captain, I will
order your chains to be taken off, and give you liberty to
walk in the court, if you will promise me to behave well and
injure no one." "Yes, I promise you," said the maniac: "but
you are laughing at me; you are all too much afraid of me."
"I have six men," answered Pinel, "ready to enforce my
commands, if necessary. Believe me then on my word, I
will give you your liberty if you will put on this waistcoat."
He submitted to this willingly, without a word: his chains
were removed, and the keepers retired, leaving the door
of the cell open. He raised himself many times from
the seat, but fell again on it, for he had been in a sitting
posture so long that he had lost the use of his legs; in
a quarter of an hour he succeeded in maintaining his balance,
and with tottering steps came to the door of his dark cell.
His first look was at the sky, and he cried out enthusiastically,
"How beautiful!" During the rest of the day he was con-
stantly in motion, walking up and down the staircases, and
uttering exclamations of delight. In the evening he returned
of his own accord into his cell, where a better bed than
he had been accustomed to had been prepared for him, and
he slept tranquilly. During the two succeeding years which
he spent in the Bicêtre, he had no return of his previous
paroxysms, but even rendered himself useful by exercising a
kind of authority over the insane patients, whom he ruled in
his own fashion.
"The next unfortunate being whom Pinel visited was a
soldier of the French Guards, whose only fault was drunken-
ness: when once he lost self-command by drink he became

**TABLE IV.**

Per centage of Deaths upon the average Number of Patients in the Public Asylums for the Insane in the United Kingdom, for ten Years, ending 1846.
quarrelsome and violent, and the more dangerous from his great bodily strength. From his frequent excursions, he had been discharched from the corps, and he had speedily dissipated his scanty means. Disgrace and misery so depressed him that he became insane: in his proverbs he believed himself a general, and fought those who opposed him, regarding both rank. After a furious struggle of this sort, he was brought to the Bicêtre in a state of the greatest excitement. He had now been chained for ten years, and with greater care than the others, footed his hands and feet being his only aid to close him, regardless of his rank. Once when he broke loose, he defied all his keepers to enter his cell until they had each passed under his legs. He was led into eight men to obey this strange command. Pinel, in his present character, never used his strength, and he was a man of original good-nature, but under excitement incessantly kept up by cruel treatment; and he had promised speedily to that condition, which promise alone had made him more calm. Now he announced to him that he should be chained no longer, and to prove that he had confidence in him, and believed him to be a man capable of better things, he called upon him to assist in releasing others who had not reason like himself; and promised, if he conducted himself well, to take him into his own service. The change was sudden and complete. No sooner was he taken in charge of the obliging and humane Pinel, knowing with his eye every motion of Pinel, and executing his orders with as much address as promptness: he spoke kindly and reasonably to the other patients, and during the rest of his long imprisonment, he did much to comfort them, as a master to his inferiors. He never heard without emotion (says Pinel's son) the name of this man, who some years after this occurrence shared with me the games of my childhood, and to whom I shall feel always attached.

In the next cell were three Prussian soldiers, who had been in chains for many years, but on what account no one knew. They were in general calm and inoffensive, becoming animated only on being conversing with other in their own language, which was unintelligible to others. They were allowed the only consolation of which they appeared sensible, — to live together. The preparations taken to release them altogether, who had been intentionally done, were in fact new severities; and they opposed them violently when removing their irons. When released they were not willing to leave their prison, and remained in their habitual posture. Either grief or loss of intellect had rendered them indifferent to liberty.

Near to them was seen an old prict, who was possessed with the idea that he was Christ: his appearance indicated the vanity of his belief; he was grave and solemn; his smile soft, and at the same time severe, appalling all familiarity; his hair was long, and hung on each side of his face, which was pale, intelligent, and resigned. On his being taken in charge of Pinel, his chains, which were the only symbol of his suffering, were removed. "I am a martyr," he solemnly replied, "Fratres sunt Dominum tum." His whole life was a romance of religious excitement. He undertook on foot pilgrimages to Cologne and Ratisbon, and attempted to convert the Indians: his dominant idea became changed into actual mania, and on his return to France he announced himself as the Saviour. He was taken by the police before the Archbishop of Paris, by whose orders he was confined in the Bicêtre as either impious or insane. His hands and feet were loaded with heavy chains, and during twelve years he bore with exemplary patience this martyrdom and constant sarcasms. Pinel did not attempt to reason with him, but ordered him to be unchained in silence, directing at the same time that every one should imitate the old man's reserve, and never speak to him. This order was rigorously observed, and produced on the patient a most deplorable effect. The heavy chains or a dungeon; he became humiliated by this unusual isolation, and after hesitating for a long time, gradually introduced himself to the society of the other patients. From this time his notions became more just and sensible, and in less than a year he acknowledged the absurdity of his previous prepossession, and was dismissed from the Bicêtre.

In the course of a few days, Pinel released fifty-three men from chains, and his procedure was imitated by all conditions and countries: workmen, merchants, soldiers, lawyers, &c. The result was beyond his hopes. Tranquillity and harmony succeeded to tumult and disorder, and the whole district was marked by the most favourable effect on the insane themselves; rendering even the most furious more tractable.
severed, notwithstanding all the obloquy heaped upon him, until a complete change of the officials and of the system was brought about.

The next asylum of which we shall have occasion to notice the history is Bethlem, concerning which we find many particulars in the evidence given before the parliamentary committee in 1816.

The severest restraint and the most cruel neglect seem to have been the almost uniform practice; and it must not be forgotten that this royal hospital, favoured with exemption from all visitation and from the effects of acts of parliament, has been, until a very recent period, the most determined in resisting the abolition of restraint, in preserving, under pretense of its being for the benefit of the patients, the more odious, and in closing its doors against inspection. With such large funds at command, Bethlem ought to be a model where the student of medicine may see every late improvement in the treatment of mental disorder carried into effect, without regard to the economy which has been detrimental to the improvement of many other asylums.

In 1810 Bethlem appeared to have been going back, rather than improving, for half a century. From the time that the indiscriminate visits of the public had been prohibited, the secrets of the institution were known only to a few. The case of Norris, a patient in Bethlem, which was made public by his own benighted confidant, has since been an incident, and it will not be out of place here. William Norris had been an officer in the navy, and was first confined at Bethlem in 1801. In 1803 he is said to have struck Mr. Haslam, the attendant, with his cudgel, from any restraint or punishment, a new and most ingenious instrument of torture was invented for his confinement. A stout iron ring was riveted round his neck, from which a short chain passed to a ring at an upper door or window. On an upright massive iron bar, more than six feet high, inserted into the wall. Round his body a strong iron bar, about two inches wide, was riveted; on each side the bar was a circular projection, being fashioned to and fastening each of his arms, pinioned them close to his sides. The waist-bar was secured by two similar bars, which, passing over his shoulders, were riveted to the waist-bar both before and behind. The iron ring passed through the neck was connected with his shoulders by a double link. From each of those bars another chain passed to the ring on the upright iron bar. His right leg was chained to the trough, in which he had remained thus engaged and confined no less than twenty years. He read books of all kinds, and reasoned quite coherently on the events of the war. During the whole of this period it was impossible for him, from the nature of the restraint in which he was placed, either to stand quite upright or to lie down at ease. It will be no matter of surprise that he died on the 20th of February, 1815.

From this time a gradual but very slow improvement in the condition of the insane may be observed. Chains were removed, and all the restraints of the older kind subverted; and more care was given to the warming and clothing of the patients. Some of the largest asylums in England were opened between 1816 and 1825. The introduction of employment among the patients, as at Hanwell, was a great advance in the amount of confidence reposed in patients; employment has since been introduced in almost every asylum, and no serious accident, so far as we are aware, has ever occurred from allowing the use of tools. The credit of declaring the total abolition of mechanical instruments of restraint to be desirable and practicable, belongs to Dr. Charlesworth and Mr. Hill, of the Lincoln lunatic asylum. The progress of the agitation was given by Mr. Hill in a lecture delivered by him at the Lincoln Mechanics' Institution, 21st June, 1838, and since published with the addition of extracts from the 'Proceedings' of the asylum, and tables showing the gradual decline of restraint. A reference to a few of these will illustrate this part of the history of the non-restraint system. The Lincoln asylum was opened on the 20th April, 1830, and was conducted from the first on humane principles, but with all the usual instruments of restraint.

On the 29th February, 1829, it is reported that a patient has died in the night in consequence of being strapped to the bed; and an order was accordingly given that the use of the strait-waistcoat shall be discontinued, except under the special written order of the physician; and also that every case of restraint shall be entered in a journal, with its nature and duration.

On the 4th May, in the same year, the "heaviest pair of iron bonds," which were jointed, and weighed 3lbs. 8oz., and the "heaviest pair of iron hand-cuffs," which weighed 1lb. 6oz., are ordered to be destroyed; five strait-waistcoats are likewise condemned.

Numerous entries in 1829, 1830, 1831, and 1832 prove the difficulty with which the change took effect. On the 14th July, 1829, is the first order for strong dresses for such patients as tear their clothes. These patients were in all asylums the most subject to continual restraint.

21st May, 1830. All the instruments which would confine the fingers were ordered to be destroyed; but manacles for the wrists and leg-locks were retained. March, 1837, the system of restraint was entirely abolished.

Mr. Hill's lecture, which contains much that is exceedingly interesting upon this subject, has the following sentence, which has been the text on which all the controversy on the abolition of restraint has been founded:—"In a properly constructed building, attended with a sufficient number of attendants, restraint is never necessary, never justifiable, and always injurious, in all cases of lunacy whatever." This sentence, when published in 1838, was declared even by those most inclined to the new system to be too occlusive, and likely to produce a bad effect; but fortunately the lapse of eight years has proved its perfect truth, by its adoption as a principle in all the most important asylums in the kingdom. But the upholders of the old system received the announcement of a doctrine so startling as if there were something atrocious in proposing to liberate those who were unfortunate enough to be insane; and for years after restraint had been actually abolished, the non-restraint system was declared "utopian" and impracticable; then declared to be practicable, but not desirable; and at length, when every other argument has failed, those who have so strenuously opposed it come forward and claim it as their own system, which they have been practising for years, excepting that it is carried a little further.

Too much stress was laid by Mr. Hill on the necessity for tall and powerful attendants; and the management of Lincoln was said to depend much on the rings of the non-restraint system, the charge of using the coercion of fear and of the hands for that of straps and chains. A form of coercion called "manual detention," wherein the attendants held violent patients quiet, was utterly discarded at Lincoln. Mr. Hill, when he visited Hanwell, was unknown in the other asylums where restraint is abolished.

The experience of the Lincoln Asylum has proved every advantage arising from the non-restraint system, notwithstanding that, among the numerous asylum attendants, many of them, from some of the medical officers, by whom every kind of unfair evidence was brought forward against the system, and the cruelties practised by unfit attendants were considered as part of it.

The next asylum in which restraint was abolished was that of the county of Middlesex at Hanwell. At the time of the appointment of Dr. Conolly to the superintendent of the asylum (Hanwell Asylum, 2nd June, 1850) it contained eight hundred patients; of these about forty were, almost constantly in restraint-chairs, and a number of others were strait-waistcoats, muffs, leg-locks, &c. In addition to these restraints, which were supposed necessary for the safety of the rest and of the officers and attendants, more than a hundred epileptic patients were fastened by one wrist in bed every night. This was considered a necessary precaution to prevent the patients from falling out of bed or from turning off their faces in a fit, and so becoming smothered, which, it is asserted, has sometimes happened. No such case has however occurred since the disuse of the hand-straps, which took place in July, 1839.

We extract from Dr. Conolly's first report (October, 1839) the following account of the discontinuance of restraint at Hanwell:—

1. Article of treatment in which the resident physician
has thought it expedient to depart the most widely from the previous practice of attending and visiting patients to the personal coercion or forcible restraint of the refractory patients. Without any intention of derogating from the high character acquired by the asylum, it appeared to him that the advantage resulting from the most uniformly strict and customary in its time of his appointment was in no respect proportionable to the frequency of its application; that the objections to the restraint actually employed were very serious; and that it was the subject of out- rages and disorders, to repress which its application was com-
monly deemed indispensable, and consequently directly op-
posed to the chief design of all treatment, the cure of the disease. 

By a list of restrictions appended to this report, it will be
seen that the daily number in restraint was in July so re-
duced that there were sometimes only four, and never more
than fourteen, in restraint at one time; but that since the
middle of August there has not been one patient in restraint
on the female side of the house, and since the 21st of Sep-
tember not one on either side. The 51st report of the
visiting justices, which accompanies this report, speaks of
the new system as requiring an additional number of attendants,
and of a superior class to those previously employed.

Dr. Conolly (1843) reports the satisfactory results of the new system. In the 53rd (April, 1840) they report that 'there has not been a single occurrence to weaken their confidence in the practicable nature
of the system, and the result of it is that the whole structure
of clothing or other property is occasioned by the personal
freedom which the patients enjoy. Indeed, so far as clothing
is concerned, the amount of destruction is somewhat lessened,
because of the general tranquillity of the patients from the adoption of the new system.'

In the 54th (July, 1840) and 55th (October, 1840) the
justices state their increased confidence in the non-restraint system, and express their entire approbation of the system of
Dr. Conolly. During the past year a suicide (by hanging)
threw the private ward of Hanwell. The patient was
selected from among all the patients in the ward; the report
of the visiting justices report the satisfactory results of the new system. In the 53rd (April, 1840) they report that 'there has not been a single occurrence to weaken their confidence in the practicable nature
of the system, and the result of it is that the whole structure
of clothing or other property is occasioned by the personal
freedom which the patients enjoy. Indeed, so far as clothing
is concerned, the amount of destruction is somewhat lessened,
because of the general tranquillity of the patients from the adoption of the new system.'

In the 54th (July, 1840) and 55th (October, 1840) the
justices state their increased confidence in the non-restraint system, and express their entire approbation of the system of
Dr. Conolly. During the past year a suicide (by hanging)
threw the private ward of Hanwell. The patient was
selected from among all the patients in the ward; the report
of the visiting justices report the satisfactory results of the new system.

The last report of the
Lincoln Asylum states that not only have suicides ceased since the adoption of non-restraint was introduced, but that the tendency
to suicide has disappeared. The latest report of Benth-
lon also contains an admission that restraints increase the tendency to suicide.

The second division of Dr. Conolly's report treats entirely of the management of the patients without restraint, and the
substitutes for it. The marked improvement in the condition
of the epileptic patients is noticed. Seclusion, however, is not im-
portant for restraint as is usually supposed.

This very useful remedial agent is styled by the supporters
of the old system 'solitary confinement,' which term is also improperly applied by the commissioners in their report.

That solitary confinement for days and weeks together reas-
sons in the practice of the days of restraint is certain; for then it was a common practice to strap a patient in bed or in a restraint-
chair placed in his bed-room. Any abuse of seclusion so great as this can scarcely now take place.

Dr. Conolly says, 'All the substitutes for restraint are, like restraint itself, liable to be abused; but none can be made such instruments of cruelty by abuse. All the substitutes have their defects; none more so than that which is of all the most useful, the most simple, and the most approved of by the highest medical
authorities, namely, Seclusion. By seclusion is meant, tem-
porary protection of the mind. It has no other object than
acting upon the senses in the refractory wards of a lunatic
asylum.'

In the sixth report (October, 1844) likewise, Dr. Conolly
writes: 'the whole of the asylum has been in great part devoted
upon the senses in the refractory wards of a lunatic
asylum.'

In the sixth report (October, 1844) likewise, Dr. Conolly
writes: 'the whole of the asylum has been in great part devoted

The room should not be dark; the shutter which guards
the window should therefore be perforated. Care should
always be taken that the perforations of the shutters should
not be so small as to prevent admission of light or air for
suicide. In the treatment of the insane nothing is trifling;
for upon careful attention to the most minute matters must
depend the perfection of the management of any asylum.

The report for the year 1844 contains many statements in
favour of the benefit of non-restraint. Dr. Conolly also states
the result of two years' experience, under sixteen heads, which
depend that difficulties must be expected in abolishing re-
straint, from the indulgence of attendants accustomed to rely
on it, and from the violence at first committed by patients
long deprived of freedom of action; but that if steadily per-
severed in it will be found to produce greater tranquillity,

fewer outrages and accidents, more general cheerfulness,
and less obstinacy and malice; that good effects will be especially
observable in patients newly admitted and treated entirely
without restraint; but that complete uniformity of feeling
among the officers, and a sufficient number of humane and
vigilant attendants, are indispensable to carry the system to
full perfection.

In this year (1844) a man aged 82 died, a consequence of
a kick given by another patient. The injury would probably
be so far, the weakness and great age of the patient produced a
fatal result. The patient who inflicted the injury was subject
to epileptic paroxysms; but was so quiet in the intervals as to
be a help in the wards, and he was actually so engaged at
the time of the unfortunate occurrence; this very patient has
become tranquil and manageable; and the ward in which the
fatal occurrence took place has become, since the abolition of
restraints, one of the most peaceful. This Hanwell Ward has
the great advantage of which the doors are always open, the windows full of
flowers, and the air clear.

Dr. Conolly's fourth and fifth Reports (1843 and 1845) contain his confirmed opinion that, 'by the abolition of
restraint, the general management of the insane has been freed from
many difficulties, and their recovery in various degrees greatly
promoted.' The sixth Report (1846) is in a great measure devoted to pointing out the erroneous notions which

Here we may consider the subject of non-restraint con-
duced so far as its practicability is concerned. If no case
requiring restraint has occurred in an asylum containing nearly
a thousand patients during six years, in which time eighteen
cases have been treated, it is unlikely that any more
difficult cases can occur elsewhere. It is nowhere insisted
that restraint can never be necessary in ill-constructed asylums,
and until houses for private patients are constructed for the
purpose for which they are used, some restraint will probably
be used in many of them. The system introduced at Lincoln,
and followed at Hanwell, was very shortly afterwards adopted
also at Northampton, Gloucester, and at the General Asylum
in Glasgow. The new asylum at Glasgow bears on its founda-
tion-stone, laid on the 1st June, 1842, an inscription stating
that one of the principles to be adopted in it is that of 'employing
mechanical rather than mechanical restraint in the treatment of
patients, which had already been abandoned for a considerable
time.' The non-restraint system was also introduced at
Hillsd Hospital, Portsmouth, in 1842, and we gather from the
Irish Reports that some asylums in that country have adopted
dordony, and Maryborough, and that very little restraint is
used at Clonmel and Waterford; and there appears every
reason to hope that it will be one of the standing rules in the
Irish District as it is in the English.
LUN 244 LUN

by far the greater number of asylums which have not yet given in their adherence to non-restraint as a principle, the use of restraint forms an exception to the rule. At Dundee, no restraint has been used for two years; this asylum was one which was connected with the non-restraint system, but when the change was made, the mental condition of the patients improved to such an extent that the method was considered successful. At Glasgow, the asylum was taken over by the city corporation and organized along the lines of the non-restraint system, when first introduced. The reports of Nottingham, Dorset, Morriston, Edinburgh, and Dumfries speak of the advantages of restraint, although the writers abstain from avail-
ing themselves of the official returns. On the contrary, St. Luke’s, Kent, Oxford, and the Retreat at York, profess the non-restraint system, while they practise the restraint.

The possibility and advantage of the abolition of restraint would seem sufficiently proved by the results reported in all these asylums; but a large number of persons still remain op-
posed to the new system, from various motives. First we must mention the unkin manner in which the subject has been noticed by the Commissioners in Lunacy; a body which had been so long paid to attend to the condition of the insane, and yet who had been proved to allow every evil to remain in the houses under their care, when all others were improving, should have been the last to despise the efforts of others. Their examples of the disadvantages of non-restraint are cruelly adduced in the hands, and are most ably answered in a pamphlet by Mr. Sejnant Adams. Many of the cases brought forward by them as proving the necessity for re-
straints, are in fact strong arguments on the other side of the question. With which of the Commissioners have they been selected, until lately, exclusively from persons ignorant of insanity, must be the excuse. The absurdities which they have allowed themselves to believe and to record, would almost cause them to have been wilfully mystified by some of the medical officers of asylums.

In the Bedford, Chester, Cornwall, Exeter, Leicester, Liverpool, St. Luke’s, York, and Pembroke asylums, coercion still appears to remain in force. The private asylums employ it almost without exception; these, being most immediately under the superintendence of the Commissioners, are in every respect the last to improve.

The asylums of the Surrey, Wakefield, and Belfast asylums have been the most consistent opponents, both in principle and practice of the non-restraint system; one assertion in the last Report of the Belfast Asylum (31st March, 1846) deserves to be quoted.

After saying that the same system with reference to re-
straint continues to be pursued in this institution, it goes on to observe, until insanity be blotted out from the "ills which flesh is heir to," or altogether changed in its more striking ef-
fects, physical restraint in some form or other—but still re-
straint—cannot be dispensed with. Truly the so-called "total abolition" of restraint appears to be only one of the many sham and specious modes introduced to perpetuate the present day. It may be that there is more difficulty in the management of Irish patients without restraint than English ones; although many of the other asylums in Ireland are without it; but this is in no way parallel to the system the latter is in so utterly inconsistent with well-known facts, proves the writer to be ignorant of the proceedings of other asylums for nearly seven years past. Taking this into consideration, we may look with some doubt upon the very curious cases subjoined, where patients request the strait-waistcoat and the muffins as favours, and pro-
mise to behave well if they are allowed the indulgence; more especially as such cases do not appear ever to be met with in asylums where restraint is entirely abolished. The absurdity of such an idea as that of a patient wishing to be put in re-
straint, is so monstrous as scarcely to deserve notice. As

readily would we believe that negro slaves are in the habit of requesting the scaffolding of a flogging, or beg-glers to allow them the agreeable exercise of the treadmill.

With the results before us of the treatment of many thou-
sand patients without restraint, and taking into consideration the experience of the system where the hands of the physi-
curables is greatly increased, we consider ourselves justified in considering that the strait-waistcoat, the coercion-chair, and the other hideous instruments of restraint, will shortly disappear like the, "chains and a straw, the starvation, the whirling-chair, and every other mean of torture formerly considered a necessary part of the treatment of those who were afflicted with insanity."

("Report of the Metropolitan Commissioners in Lunacy to the Lord Chancellor," 1844; "Statistical Tables prepared by the Metropolitan Commissioners in Lunacy," 1844; "An Act for the Regulation of the Care and Treatment of Lunatics" (S. & G. 9 & 10 Vict. c. 120); "A Bill for the Provision and Regulation of Lunatic Asylums for Counties and Boroughs, and for the maintenance and care of Pauper Lunatics, in England" (S. & G. 9 & 10 Vict. c. 120); "Report of the Inspector General of the Lunatic Asylums in Ireland," 1846; "Returns from each District Lunatic Asylum in Ireland," 1845; "Reports of all the principal Asylums in England, Scotland, and Ireland, and infor-
mation respecting the sundered by many the facts of the House of Commons, 1846; For the "History of the York Hospital for the Insane," "The Description of the Retreat near York," "On the Description of Lunatic Asylums," Brown’s "Lectures delivered before the Managers of the Montrose Lunatic Asylum," Remarks by Mr. Sejnant Adams on the Report of the Metropolitan Commissioners in Lunacy; Personal knowledge of the Mid-
dees Lunatic Asylum, Hanwell.

The custody of the insane in Scotland is, like every other matter of importance, demanded both magisterial and executive inter-
vention, connected with the system of local courts. The law on the subject is contained in three statutes: 55 Geo. III. c. 69; 9 Geo. IV. c. 34; and 4 & 5 Vict. c. 60. By these laws two classes of institutions are mentioned: one an asylum, or private asylum, without a warrant from the sheriff. Any person accessory to a breach of this regulation is liable to a penalty of 500; and if he be the keeper of the asylum he is liable, too, to a fine of two hundred guineas, and to imprisonment not exceeding three months’ duration. The sheriff is also empowered to grant a warrant unless on the report of a qualified physician or surgeon; and the person granting such a certifi-
cate is liable to a penalty of 600, if he has omitted carefully to examine the patient. The keeper of every house where two or more insane patients are kept requires a licence for an asylum. Any person acting as keeper to an insane individual, or his instrument, must make an annual report to the sheriff, certified by two medical men of the state of the pa-
tient, and must notify the death or removal of the patient. In every licensed asylum a "ward-house register" must be kept. By the act of 4 & 5 Vict. this register is appointed to be annually transmitted to the sheriff, sealed up, and the seals being broken by him, he seals the book, and retransmits it. When a patient dies in a licensed asylum, a report must be made to the sheriff within twenty-four hours, accompanied by a certificate from the medical attendant, stating the nature of the disease, the length of time during which it has continued, the time when his attendance was first required, and the reasons for the tardiness, if any. The sheriff shall not open to the inspection of the sheriff. In the general case, the sheriff or his substitute may perform the duties of the office regarding lunatics; but it is especially provided that all questions relating to the treatment of lunatics shall be within his jurisdiction, and either he or his substitute must make a second; in these visits they are accompanied by medical inspectors. The medical bodies in Edinburgh and Glasgow elect inspectors for their respective districts; in other parts of Scotland they are chosen by the sheriffs from the qualified medical practitioners.

It is believed that the system of the management of the insane in Scotland has, both in a purely medical and in an ad-
ministrative point of view, been lately vastly improved. Until a comparatively late period the statute law was nearly inoperative, from a strong natural prejudice against the en-
forcement of its provisions. We venture the statement to the treatment of the insane, and the consequent toleration for breaches of the sta-

tutory regulations. The general rule adopted in practice was, that insane persons were allowed to go at large until they chose to return. The houses of the county, and their neigh-

bours, and that when confinement was in any case resorted to, the proceedings were not very rigidly investigated. It is believed that the law is now generally obeyed, and that the necessity of the employment of the county justicemen is under-
tific advice, is felt by all who are connected with them, or concerned in the administration of the law. The Com-
mis

sions who in 1844 reported on the state of the poor in Lunatic Asylums, declared that "in many instances the system of the County is so grossly defective," that they are of opinion that the system of the County is so grossly defective," that they are of opinion that the
LUTZELBURGER, or LEUTZELBURGER, Hans, called also Hans Franz, an early Swiss wood-engraver of Basel, about whom very much has been written, but as yet very little is known. He lived in the early part of the sixteenth century, and is supposed by some to have cut the designs of the celebrated woodcut series of 'The Dance of Death,' attributed to Holbein. This supposition, however, is founded solely on the facts of his being contemporary with Holbein and the circumstance of one of the cuts being marked H. L. This is maintained by some writers and combated by others, and especially by Rumohr in 1856, in a work entitled 'Hans Holbein der Jüngere in seinem Verhältniss zum Deutschen Formschmiedwesen' (Hans Holbein the younger, in his relation to German wood-engraving).

There are many other celebrated old cuts, singly and in sets, some from drawings by Holbein, which are attributed to Leutzelburger, and which are described at length in the Kunstblatt, and in the works of Ketsch, Heller, Mastmann, and other writers on wood-engraving. The views of all parties are stated with considerable detail in Dr. Nagler's Neues Allgemeines Künstler-Lexicon.

LYZULA, a genus of plants belonging to the natural order Juncaceae. It has a 1-celled 3-valved capsule, without dissepiments, with three seeds at the base of the cell. Several species of this genus have been described. L. symphyta, the corn-lichen, is a native of Great Britain. L. campestris is common in the pastures of this country, and seven species are natives of the British Islands.

LYCHINIS (from λύχη, a lamp), a genus of plants belonging to the natural order Silene. It has a 5-toothed naked calyx; 5 petals, clawed; 10 stamens; 5 styles; the capsules 1-celled, or half-5-celled, opening at the top with five or ten teeth. The species are smooth, hairy, or downy herbs, with terminal corollas of flowers, rarely solitary.

L. Chalcodromica, the Scarlet Lychnis, is a smooth lanceolate plant, with rose-coloured flowers in bunches; the calyx cylindrical, 5-cleft; the calyx 2-lobed, the corolla long; the leaves lanceolate, slightly coriaceous at the base, and clasping the stem. This plant, which produces scarlet, rose-coloured, or white flowers, is a great favourite in our gardens, it is a native of Siberia and Japan. Several varieties of this plant have been named.

L. grandiflora is a glabrous plant, the flowers solitary or terminal, terminal and axillary; the calyx tuberous, clavate, ribbed; the petals inserted; corolla elongated; the leaves ovate, almost sessile. It has large beautiful scarlet flowers, and is a native of China and Japan.

L. Flos Cuculi, Ragged Robin, has 5-7-cleft leaves, with a very short stalk; it is rose-coloured, petal-sheathed, and is an abundant plant in the moist meadows and pastures of Great Britain, as well as the whole of Europe.

L. repertina, White Campion, has the petals half-bifid, and of a soft, pinkish, velvety red, with the calyx reflexed. The flowers are often cultivated, and the plant has a sweet smell. It is a native of Europe, and is cultivated in gardens.

L. diurna, Red Campion, has the petals half-bifid, the calyx teeth of the fertile flower triangular, the capsule nearly globular, the teeth reflexed.

The other British species of the genus Lychnis are: L. Githago, the Corn-cockle, a pretty plant blossoming in cornfields from June to September; L. alpina, found on the mountains of Forfarshire; and L. Vitacea, a rare plant.

Many of the foreign species are cultivated in our gardens. They thrive well in a light rich loamy soil, and may be propagated by cuttings or seeds.

(From Gardener's Dictionary; Babington, Manual of British Botany.)

LYCIA. In addition to the general description of the country in the P. C., and the geographical details in the article Anatomia in the Scoto-Hibernian, on page 1112, we give a few particulars respecting the inhabitants and natural productions of this most interesting portion of Asia Minor.

The country is, as it seems, well inhabited, chiefly by Turks, many of whom lead a life half settled and half nomade; they are distinguished above all other inhabitants of Asia Minor by their excellent character. Most of them are farmers, and some are traders, particularly the Armenians and Greeks who live in the sea towns, and form the greater portion of the population of the inland town of
Almali, which is the largest in Lycia, the population being about 25,000. Those among the Turks who wander with their herds on the high plateaus, like the Turcomans, show an independence of manners and character not very pleasant to the traveller, but on nearer acquaintance they appear to be a sort of dying race. The Turkish peasant is exceedingly careless about money, and when they have enough to eat and to drink,—and they are moderate in their habits,—they are satisfied and care for nothing more. They are somewhat shy and suspicious, through being treated as they are by Turkish officers and the Sultan's officers, who take away every thing they please without paying for it. Among the coast of Lycia as well as the adjoining provinces of Asia Minor, there lives a breed of cats known as the "Lyly,"* which term is here applied to the leopard, and is an Arabic word meaning the "Euphuism." There are also the "Sanho" and "Iror," or the "Peris" (perhaps the panther), commit great depredations among the herds; great numbers of them are annually killed, and a reward of from 100 to 200 piastras is given by the government for each "sanho." They are very frequent in the district of Sidymes on the coast. The ox is precisely the same as represented on the ancient coins and monuments of Lycia; but there is also a species of dwarf ox, of the size of a large dog, though much stouter; they possess large numbers of these oxen and camels. The breeding of horses is carried on to a great extent, and herds of many hundreds are often seen grazing together in the valleys. The only kind is that of which such spirited representations are seen in the ancient sculpture. The breed of Armenian horses is of a large size, the feet are remarkably fine and thin, and the ears are small, as in the antique. They are not shod. The rivers and lakes abound with large tortoises, and on their banks the trees swarmed with the green climbing frog. No part of Asia Minor contains such splendid valleys as those of the Xanthus and the Dolymon Chai. Myrtle, oleander, and pomegranates cover the banks of the rivers; the plain along the rivers are well cultivated, and in many places the fields are enclosed by fences of myrtle and the small prickly oak, mixed with the orange, the wild olive, the pomegranate, the oleander, the elegant green storks, which are most beautifully metled together by vine, clematis, and very other climbers. Fruit trees are planted in enclosures. The hills are covered with large oaks and planes, which supply excellent timber, of which, however, only small quantities are shipped from the coast towns. The oak, 'quercus sepilina,' is a source of wealth from its abundant "velaines" of the Smyrna merchants, which is used in tanning leather and gives it that agreeable smell which places the Turkish leather even above the Russian "Jacht." A sort of horse named "Pakiri," does not exist for table use. In proportion as the traveller approaches the high upland plains, the tender fruit-trees, as well as the olive, the aloe, and the palms, and plants disappear, and are replaced by walnut, apple, and other trees. The hills around Almali, which is 4000 feet above the sea, is one of the largest and best cultivated corn tracts in Asia Minor; its chief produce is wheat, of which some half-fabulous food for horses. Mainis is chiefly raised in the valleys and on the hills.

LYCOPERSICON.

SYRIA.

The first mentioned works of Lycy gave the name of Euphuism to a fashionable style of language, of which, although he certainly did not invent it, he contributed much to perfection. The Euphuism of Lycy himself was just an exaggerated form of that straining, pedestrian, over-elaborated style which has been discredited by the age as well as in literature about the middle of Elizabeth's reign. In his hands it added to the classical pedantry of the day a pedantry of something like science, consisting in incessant digressions, and in the language of mathematics, history, and natural history. Drayton, in ascribing to Sir Philip Sidney (himself a simple writer) the merit of having brought back the tone of language to nature, speaks of Lyly as

Shakespeare's Don Armado has sometimes been considered as parleying Euphuism; but, as Mr. Knight has observed, there is a nearer approach to this jargon in much of the language used by the highest personages in the same play. The absurdisties of it are belittled by Jonson in his 'Cynthia's Revels.' Sir Fretier Shafton, in 'The Monastery,' is an unsuccessful attempt at representing the characteristics of Euphuism. Lyly's Book of the Duke of Lenox is the only comedy deformed by the same false taste; yet they exhibit occasional touches of fine fancy, which however is shown to greater advantage in some of the short lyrical pieces interpolated through them. The wit of them is one of the most original that exists. In porportions of character these plays can make no claim; and as little can their mythological, pastoral, or classical story, be said to possess dramatic interest, or to be treated with dramatic force. The author's style is very much like a dramatist's ruse almost wholly on his position as one of Shaker's immediate predecessors; and on that the facts plays present, in strong relief, some of the distinctive characteristics of the literary influence which prevailed in the interesting age.

LYON KING AT ARMS. [HERALD, P. C.]
LYSIMACHIA, a genus of plants belonging to the natural order Primulaceae. It has a 5-parted calyx, a rotate corolla with 5 (rarely 4) petals, and a 5-lobed ovary. The stamens are inserted at the base of the corolla, and are 5 in number. The capsules open with 5 valves.

*L. thyrsiflora* is distinguished by its axillary stalked dense racemes of the flowers; the leaves are opposite and lanceolate. The corolla is divided almost to the base into 5 narrow petals often separated by a minute tooth, which as well as the calyx is yellow spotted with orange. It is found in marshes in the north of England.

*L. vulgaris* has an erect stem, with compound terminal and axillary panicles, ovate or ovate-lanceolate leaves nearly sessile or 3 or 4 in a whorl. The petals are entire with glabrous surfaces, and oblong for half their length. This species is the *L. punctata* of some botanists, and probably the *L. punctata* of Dickens, *ibid. iv. cap. 3.*

*L. nummularia*, Moneywort, has a prostrate creeping stem, solitary axillary flowers, ovate acute sepals, and glabrous filaments connected at the base. The leaves are opposite, roundish, and shortly stalked. The peduncles shorter than the leaves. It is found in damp places in Great Britain.

*L. nemorum* has linear lanceolate sepals, smooth distinct filaments, and opposite oval acute leaves. It is found in woods and damp shady places in Great Britain. *L. astroterpaeus* (elater) is a native of Europe and of Europe. It is the only species of Lycopus which has smooth stems.

M. CRIE, THOMAS, a writer on ecclesiastical history and polemics, was born at Dunse in Berwickshire, in November, 1772. His father was a petty manufacturer and trader, who had by his industry and economy been enabled to accumulate a property, and spend his time in quiet and spiritual dependence. 'Dr. Crie's parents,' says his biographer, 'being connected with that branch of the secession usually termed Anti-Burghers, he was brought up under the ministry of Mr. M'Crie, at a period when the strictness of that communion was retained in a measure which is now wholly unknown. In these circumstances he received a thoroughly religious education, of the importance of which he was ever afterwards so strenuous an advocate, and of the success of which he was himself a striking example.' Having received the rudiments of education at the parish school of his native place, he afterwards studied at the University of Edinburgh, which he entered in 1785. Contemporaneously with his academical studies, he occupied himself in teaching younger lads, an employment for which he seems to have been well qualified. In 1791 he commenced his peculiarly theological studies. In 1795 he was licensed as a clergyman by the associate presbytery of Kelso, and he was immediately afterwards chosen pastor of a congregation of the same body in Edinburgh. In the earlier period of his ministry he entered warmly into those discussions naturally prevalent among bodies who have so many points of repulsion from each other as the small Presbyterian sects which had sprung from the church of Scotland. He soon commenced however the important task of studying, for the purpose of some undefined literary projects, the early history of the Presbyterian church in its connection with its most remarkable characters. The body to which he belonged followed a rule of Presbyterian discipline, from the strictness of which they maintained that the established church had diverged; and, recurring perpetually to the conduct of the fathers of Presbyterianism, it was like any member of this body with sufficient talent would be the most zealous biographer of those primitive worthies. In 1812 he published 'The Life of John Knox.' Scholarship or literary ability were qualities which the clergy of his sect, consisting almost entirely of the humbler members of society, were never expected to display; and this first attempt, which showed both qualities in an eminent degree, accompanied by much patient research, was looked on as a literary phenomenon. In 1813 he received the degree of D.D. from the University of Edinburgh, previous to the appearance of the second edition of his work. It has since passed through several editions, and, with the increase of the body to which he belonged, his work increased in value. His knowledge of Scotland, is highly esteemed by historical students. In 1819 he published a work of still more extensive and curious research, 'The Life of Andrew Melville,' a celebrated champion of Presbyterianism in the reign of James I. of Scotland. Indefatigably he pursued the researches connected with this volume, and it is scarcely matched in the English language, and it had the effect of revivifying from the most obscure materials—records of births, marriages, and deaths, ecclesiastical and proprietary registers, and like sources—the circumstances connected with the lives of some interesting men who in the stir and bustle of their own active age had failed to find commemoration. The partizan zeal with which those works were undertaken is not their least remarkable feature, and obtained from Mr. Hallam the apt designation of 'Presbyterian Hill-debrandam.' There is no doubt of the accuracy with which Dr. Crie stated facts and cited authorities, and that he was thoroughly honest; but from the beginning to the end each piece is a work of industrious and acute special pleading, and the reader whose position enables him to take an impartial view of the characters dealt with, is likely to pronounce what portions may be favourably dwelt on, and what should be hastily passed over, if not omitted. His pallinations and vindications are singularly ingenious; and amid all the rude morality and the savage acts of the turbulent age of which he writes, he preserves the history of his sect without passion and in accordance with the spirit of history which digresses his own heroes from all follies as well as from all vices; even the destruction of the Scottish ecclesiastical buildings has its meed of praise. Written in such a spirit, and being works of genuine learning and research, they are very popular with the ultra-Presbyterian party in Scotland. Their author led a blameless simple life, on a small salary, which, with the free use of the valuable public libraries in Edinburgh, contented his unerring disposition. He died on the 8th August, 1836, deeply lamented by the members of his congregation and a wide circle of private friends.

(Life of Thomas M'Crie, D.D., by his son, the Rev. Thomas M'Crie, 1840.)

MAC CULLOCH, Dr. JOHN, was born in Gurnessay, on the 6th of October, 1773. He was descended from an ancient Scottish family, the MacCullochs of Nether Ardwall, in Kirkcudbrightshire, a younger branch of the MacCullochs of Myretown, a family which at one time possessed considerable property in Galloway. He was the third son of James MacCulloch, Esq., and Elizabeth, daughter of Thomas De Lisle, Esq., one of the jurats of the royal court of Gurnessay. In his childhood Dr. MacCulloch was very thoughtful, and fond of being alone. He taught himself to write, and wrote Latin exercises at an age when many children have barely acquired a knowledge of the alphabet. He seldom played with other children, but when the hours of study were over was in the habit of going into a room which his father, who was a man of scientific and literary attainments and a good mechanic, allowed him to call his own, and the door of which he contrived to fasten a large bent needle in such a manner as to prevent his brothers entering. Here he amused himself with drawing, carving various articles in wood and cocoa-nut shell, and, at a very early period, in attempts to make gunpowder, and, after he had effected that, in manufacturing fireworks. His family was at this time residing in Cornwall, and the first school he was sent to was the grammar-school at Plympton. He was afterwards removed to one at Penzance, and, from the grammar-school at Lostwithiel, where he remained three years, and where his talents seem to have been appreciated by the master, Mr. McGilvray, of whom Dr. MacCulloch always spoke with the greatest respect and love.

In 1790 he went to prosecute his medical studies at Edinburgh, where he obtained his diploma of physician, at the age of eighteen. He subsequently entered the artillery as assistant-surgeon, and on the 5th of April, 1803, accepted the situation of chemist to the Board of Ordnance. In 1807 he read at Blackheath, where he practised as a physician. His application while pursuing his studies at Edinburgh was intense, and probably received an additional stimulus from the circumstance that his father, who was settled as a merchant in Bretegan, was arrested at the beginning of the French revolution, and one of his most valuable assets, a large house in Edinburgh in the Reign of Terror, a state of things which naturally put a stop to the lucrative business in which he was at that time embarked. During Dr. MacCulloch's occasional visits to Penzance, with his father's consent, he engaged in the drug business. As a young man, he became acquainted with Sir Humphry Davy, who was indebted to him for some of his earliest instruction in chemistry.

About the year 1811 he was engaged by government to make various surveys in Scotland. He in consequence gave up his practice, which he never regularly resumed, although he was frequently consulted. The first business on which he was employed in Scotland, was in a search for stones adapted to the use of the government powder-mills. The second was an examination of the principal mountains, with a view to the repetition of the experiments which had been made at Schehallian on the density of the earth. The third had for its object the correction of the deviations of the plumb-line on the meridian of the trigonometrical survey. Whilst he was making these surveys, he also employed himself in geological observations, and it is stated that he knew the geological map, as well as for his own amusement and instruction as with the hope that they would be useful to the country. In 1826 he was desired by government to complete the work which he had begun, and this was commenced for the government public work in which he was employed - the mineralogical and geological survey of Scotland, which was continued every summer from 1826 to 1832, when he completed it. The winters of these years were spent in the tedious task of putting in order the observations made in the summer, in
drawing sections, and preparing the map. This great work, precise and exact as it is, the labour of one individual, begun, carried on, and completed by himself alone, extending over a country richer in its variety of rocks than any country of equal extent in the world, is in itself a most remarkable instance of human industry and skill; and it is now, perhaps, as little known as it has never been surpassed, or even equalled, by any undertaking of a similar nature. In making this survey Dr. MacCulloch had to contend with many hardships, for great part of it was done in the Highlands of Scotland, or in miserably poor comfortless land. It was his lot to do all the different works provided for in all other surveys by half a dozen men and as many salaries. As a proof of the ability with which he performed his important duty, we must make mention that he steered his own boat through the dangerous channels of the Scottish islands.

Some of the fruits of these separate surveys are published. The first publication was 'A Description of the Western Islands of Scotland, including the Isle of Man,' 2 vols. 8vo., with 1 vol. 4to. of plates, London and Edinburgh, 1816. Next, 'A Geological Classification of Rocks, with Descriptive Synopsis, comprising the Elements of Practical Geology,' London, 1821, 1 vol. 8vo. Thirdly, 'The Highlands and Western Isles of Scotland, in a series of Letters to Sir Walter Scott,' London, 1834, 4 vols. 8vo. This work, in addition to a most graphic description of the country, which some learned dissertations on the history, antiquities, language, music, and economy of the Highlands. Fourthly, A System of Geology, with a Theory of the Earth, and an Explanation of the Glacial Hypothesis; 2 vols. Edinburgh, 1831, 2 vols. 8vo. In 1821 he published a Treatise on the Art of making Wines, which reached a fourth edition in 1828, and in 1830 he published anonymously an account of Blair and Dunkeld, forming a guide-book for the antiquities. He contributed many papers both to the Encyclopædia Britannica and to Brande's Journal, on various subjects connected with Scotland generally, or its rocks and minerals; besides others on different topics. One of these is a description of twenty-two species of Medusa found about Shetland and Orkney; so attentive was he to everything that surrounded him. He published many articles in the 'Transactions' of the Geological Society, and wrote frequently in the Edinburgh, Westminster, and Quarterly Reviews, and in the London and New Monthly Magazines.

Although unable to follow up the practice of his profession, Dr. MacCulloch never lost sight of it, the proofs of which we have in two elaborate works which appeared in 1827 and 1828. The first is entitled 'Malaria, an Essay on the Production and Propagation of this Poison, and on the Nature and Localities of the Places by which it is produced,' &c., 1 vol. 8vo., London. The second is 'An Essay on the Remittent and Intermittent Diseases, including generally Marsh Fever and Nereis Fever,' 2 vols. 1828. In 1830 he published a paper in which he first referred a large list of disorders, hitherto deemed anomalous, and which appear to have nothing in common with one another, to their true source—the poison of the malaria. This was the more remarkable inasmuch as they must have resulted from deep thought, based on an intimate knowledge of the subjects he treated of. The acquisition of this knowledge was gained by intense study, aided by a wonderfully retentive memory. The variety of his acquirements was not less remarkable than their extent. Allusion has been already made to his knowledge of medicine, geology, mineralogy, chemistry, and mathematics. He was also well acquainted with theology, astronomy, zoology, botany, physics, and the mechanical arts. He was skilled in architecture. He drew well, and has left an immense number of drawings. He was a good musician, and his musical compositions show that he was very familiar with the general structure of the science. His accomplishments, as they are called, were cultivated at times which many persons pass without employment. His drawings were done while others were employed in such duties as those described, and his scientific specimens dried, and painted before breakfast in the long summer mornings. When he used to practise music, he did so during the twilight hours. In short, no portion of his time was unoccupied, and the multifariousness of his labours was still more remarkable from the fact, that for many years he was afflicted most severely by the effects of malaria.

He was also the author of 'Pictorial Tracts,' the 'Pictorial and Illustrations of the Attributes of God, from the Facts and Laws of the Physical Universe; being the Foundation of Natural and Revealed Religion.' It was intended for publication in the following year, but appearance was delayed by the announcement of the Bridgewater Treatises. In obedience to his last will, it was published in 1837, in 3 vols. 8vo. Many papers on various subjects remain unpublished, and among them a corrected copy, with numerous additions, of his work on the Highlands of Scotland.

Dr. MacCulloch was fellow of the Royal, Linnean, and Geological Societies, and at one time vice-president of the last. In 1820 he was appointed physician in ordinary to Prince Leopold of Saxo-Coburg. For some years, and till his death, he filled the situation of lecturer on chemistry and geology at the East India Company's Military Establishment at Addiscombe.

He married, in the summer of 1835, Miss White. He was with her in Cornwall, on a visit to an old friend, when the accident occurred which led to his death on the 21st of August, 1835. He was thrown out of a pony phaeton, by which, in addition to other injuries, his right leg was so shattered that amputation became necessary. He only survived the operation a few hours. He was buried in the churchyard of Gulliv, a village near Penzance, in which his family had at one time resided.

Dr. MacCulloch was steady in his attachments, zealous to promote the interests of his friends, and ever ready to aid those who needed his assistance. He possessed very strong affections and sensibilities, which for many years seemed rather to have increased than diminished. His manners were courtly; his conversation was rich, varied, apparently exhaustless, though never urged so far as to exclude others, and his geniality was such that he was always as willing to impart information as he was eager to acquire it.

(Principally from the Annual Biography and Obituary for 1836.)

MACDONALD, ANDREW, an unfortunate man of letters, furnishes the theme for one of the most affecting passages in D'Israeli's 'Calamities of Authors.' He was born about 1745, and was the son of a gardener in Leith. After having been educated in the University of Edinburgh, he took orders in the Scottish episcopal church, and in 1777 became pastor of a congregation in Dumfries. In 1780, he published a Poetical Fragment,' in Spenser's stanza. This volume was succeeded by a novel called 'The Independent;' and afterwards a tragedy of his, called 'Vimonda,' was played with success in the theatre of Edinburgh, with a prologue written by Henry Mackenzie. Becoming tired of a charge very ill remunerated, and being encouraged by the reception of his play, he resigned his place, and came to Edinburgh; first however marrying the servant-maid of the house he had lodged in, and then living for a short time very extravagantly. He next removed to London, where, in 1787, his tragedy was brought on the stage by Colman with much pomp and very considerable success. A stranger of a congregation, he was converted, and in 1791 was commanded to leave his house. He was called to London, leaving his wife and child in beggary. A volume of his sermons was published in 1790; and a volume of poems, including 'Vimonda' and three other plays, appeared in 1791. His dramatic genius cannot be rated high; but he possessed no inconsiderable power both of poetic fancy and of expression. There is a good deal of vigour in some of his light poems, written in London, in the manner of Peter Fingarette.

MACDONALD, ETIENNE JACQUES JOSEPH ALEXANDRE, Duke of Tarentum and Marshal of France, was born on the 17th Sept., 1765, at Sancerre in the department of Cher, though some authorities make Sodan the place of his birth. He was descended from a Scotch family, which, on account of its participation in the rebellion of 1745, was compelled to seek refuge in France. He was entered as a private in a regiment of dragoons, and afterwards joined the regiment of Dillon, chiefly composed of Scotch and Irish, in the French service. He was induced, it is said, to remain in France at the breaking out of the Revolution, on account of his attachment to the daughter of Mon. Jacob, who warmly espoused the republican cause. His military talents procured him a place at the commence ment of hostilities on the staff of General Dumouriez, and he rose to the rank of Captain after the battle of Jemappes; some historians however state that his valor on that occasion was rewarded with the rank of Colonel. He served in the campaign against England in 1792, and distinguished himself by the passage of the Waal on the ice, under a severe fire from the batteries of Nimeguen, by which exploit the Dutch fleet was captured. Having risen to the rank of General of Division, he was summoned to 1796, Vol. II. - 2 K
at Düsseldorf and Cologne. He then joined the army of the Rhine, and afterwards that of Italy; and when in 1798 the French became masters of Rome, Macdonald was appointed governor of that city. His behaviour in one respect was approved by some patriots, but his position was one of extreme difficulty. On the approach of General Mack he was obliged to abandon Rome, and his army was attacked by the enemy at Oriolo; but the Austrians however were compelled to retreat before the superior force of Suwarrow, he saved the army, and reconstituted it to France by a retreat in which he displayed considerable skill. (Suvarov, 27, C.)

Macdonald had command at Versailles during the period of the revolution of the 18th Brumaire. (Bonaparte, F. C.)

In 1800 he was appointed commander-in-chief of the army of reserve in Switzerland. His celebrated passage of the Splugen, the diversions and difficulties which he surmounted, the persevering ability which he displayed, have rendered his name greatly celebrated in the annals of warfare. There are indeed but two events recorded in history to which this memorable exploit can be compared—the passage of Hannibal across the Alps, and that of Napoleon over the Great St. Bernard. Alison, in an elaborate comparison which he makes between the latter and that of Macdonald, considers that this general displayed the qualities that rendered his name memorable, while he had less means at his command to surmount them. (Alison, Hist. of Europe, c. xxii.)

In March, 1802, he was appointed French ambassador at the court of St. James, and on his return to Paris he was created Grand Officer of the Legion of Honour. He afterwards remained some years without employment, on account of the free expression of his sentiments with respect to the conduct of the First General towards General Moreau. (Bonaparte, F. C.; Morau, P. C.) It was not until the year 1809 that he was recalled, to military service, when the command of a division of the army of Italy under Eugene Beauharnais was given to him. Here Macdonald on the occasion made such a noble use of the opportunity of renewing his military reputation. The troops under his orders entered Styria; he compelled the Austrian general Meerfeld to capitulate at Lajauch (May 22, 1809); and he shared the glories of the victory of Raab. He was present on the 6th July at the famous battle of Wagram; the important duty of forcing the enemy's centre, which was defended by two hundred pieces of cannon, was committed to him, and he executed this critical movement with the most consummate skill and bravery, but with immense loss. On the morning after this great and singular engagement, Napoleon, as he passed by Macdonald on his return to the capital, stopped, and, as a pledge of their reconciliation, paid him a just tribute of praise for his share in the victory, and as an earnest of his admiration presented him with the marshal's staff. On this field of battle two of the most distinguished regiments of the national guards, services, Marmon and Oudinot, who afterwards obtained the respective titles of Tucque of Ragusa and Reggio. It is also added that Macdonald with affectionate gratitude for the honour conferred, and especially for the manner in which it was conferred, pledged himself to abide by the dictates of Napoleon for life or death.

He was afterwards appointed governor of Gratz, whereby the strict discipline he maintained among his troops he so conciliated the esteem of the inhabitants, that on his leaving the town they begged his acceptance of a most valuable gift of their and his daughter, and who was about to be married. This gift however he nobly refused, and added that the best proof of their gratitude towards him would be shown by their care of three hundred sick soldiers, who had been reduced to have been left alone, to add to his military reputation. On one occasion indeed he was engaged in an enterprise which has tarnished the glory of his previous exploits. After the fall of Torton (March 29, 1810), he was one of the prisoners on board the Leipsic, which was proceeding from Livonia to Har-}

elona by the circuitous route of Marennes. He was attacked on his march by the Spanish general Sarafild, and his troops met with a determined opposition on the bridge of Mancres; this disaster overcame, the French, or rather the Italians in the French service, forced their way through the town, whose inhabitants offered them no resistance, and they wreaked their vengeance upon it by setting fire to its buildings. Seven hundred houses were destroyed, its public edifices set on fire; and it is to be regretted that Macdonald, who witnessed the conflagration, made no efforts to put a stop to, and offered no assistance to the sufferers. This unnecessary cruelty was condemned by everyone, and rekindled all its vigour that guerrilla warfare which proved so harassing in its effects and so important in its ultimate results.

In 1812 Macdonald accompanied Napoleon in the expedi-}

tion to Russia. In the attack on Riga, which Napoleon gave under his command. In the Saxon campaign of 1813 he distinguished himself at the battles of Bautzen and Lützen. In that of Coalbach (August 29, 1813) he met with a severe reverse. In direct violation of Napoleon's orders, he imprudently ad-

anced against Marshal Blücher, who was at the head of an army very superior in numbers to his own, which was im-}}
and two on Appellations. According to Priscian be also were Ambrose.

MACHINERY. It is proposed to consider in this article the influence which is exercised by machinery upon the general interests of mankind, and especially upon the well-being of different classes of society. There is no subject in the present age in which there is more productive of good; and none perhaps in which all classes are so much concerned. Whatever theoretical opinions may be entertained by speculative men, the use of machinery in aid of human labour, or, as some contend, instead of it, is increasing, and cannot be restrained; it is right therefore for all men to endeavour to judge for themselves in what manner it is valuable to society, and what objects it is extended to be real or imaginary. By some, new every machine is productive of injury to the emotion of the wealth and resources of a country; by others it is regarded as a hateful rival of human industry—as iron contending with ironing steam—as steam fighting against life and blood of man. The one view is full of hope and promise; the other is fraught with gloom and sadness. One would present society advancing in wealth and comfort; the other would show it descending faster and faster into wretchedness. But even those who believe that the inventive faculties of men have been engaged in devising for themselves a curse, would gladly be convinced that cheerful anticipations of good are consistent.

The influence of machinery is of two kinds: 1st, as it affects the production and consumption of commodities; and 2ndly, as it affects the employment of labour.

1st. As to production, it certainly is true that machinery have been well described to be the same as if every man among us had become suddenly much stronger and more industrious. (Results of Machinery, 7th edit. p. 38.) If, by the aid of machinery, ten men can perform the work of twenty, and so form it better and more quickly, the products of their labour are as much increased as if they had really 'become suddenly much stronger and more industrious,' and, it may be added, more skilful. The same is the case to a great extent with all labour, is more abundant, and society enjoys the results of industry at a less cost. Who can doubt that this is a great benefit, unless it be attended with evils which are not at first perceptible? No man labours more than is necessary to effect his object, and his constant desire is to contrive modes of saving his own physical exertions. A rich soil and a fine climate are universally esteemed as blessings because the people enjoy abundance with comparatively little labour. A poor soil and bad climate are evils, because the husbandman must labour much though the produce of his industry be small.

Labour without adequate results is always regarded as a curse, and great indeed is human inventiveness of the earliest times, has had for its objects the saving of labour and the increase of production. Horses and other beasts of burden were made to work for man; to bear loads which otherwise they must have performed by their own strength, and so make their own strength more must have forced through the soil. To the same object all nature has been made subservient. The stream turns the mill, and does the work of man; the wind performs the labours of man. In their way, the machinery is labour of carrying their goods to a distance, and it is less labour to raw the boat than to carry its cargo; but rowing is laborious, and sails were invented that the wind should do the work of man. In all other matters it has been the same. Man is weak in body, and ill endowed by nature with the means of self-preservation and subsistence. Many animals are stronger and most animals are more active than himself; they can provide their prey with more certainty, they are armed with weapons of offence and defence, and they need no shelter from the weather but that which nature has provided; their own strength must have saved them beyond the heart; but his hands were formed with wondrous aptitude for executing the tasks which reason set them. He invented tools and implements and weapons, and all nature became his slave. He was now able to make his own strength more almost as if he had become stronger and more industrious. He produced more for his own comfort and subsistence, with little labour, than the greatest cutting could otherwise have obtained for himself. He made shoes and clothes for the protection of his body, has increased his strength, and multiplied the productions of his industry; and at length the giant power of steam has peopled the world with inanimate slaves who do his work faster and better than he did it himself with the greatest labour and the most skilful tools.

The flint and fish-bone of the savage, the tool of the workman, and the steam-engine of the manufacturer, have but one common object—to save the labour of man and to render it more the more productive. As far as machinery attains this object the most effectually. Can any one doubt the advantage of abundant production? It needs but a few words to point out its benefit. Whether for man or for God, we are more beyond the payment of the consumption of the necessities of liwe; we all desire comforts, luxuries, and ornament; and in proportion as we desire them we become civilized. The more skilful the man who manufactures, the more exceedingly he farper his arts, his sciences, his polities, and its absurdities; but it seems the law of our nature to advance to that state, and with the increase of artificial wants our intellect becomes more active and collective, refinement of manners succeeds to barbarism, and all those moral qualities for which man is distinguished, become developed. We may conceive some Utopia in which all the noble parts of man's nature are cultivated, while his wants remain simple and easily supplied, but the world we live in presents another picture. We might wish it were otherwise; but it is in vain to deny that refinement is the accomplishment and, in some degree, the consequence of riches. The riches that have not been elevated by the increase of wealth. It follows therefore that to multiply the objects of comfort and enjoyment which human industry can produce, is to improve the state, and to act more skilfully and intellectually being, and to minister to their enjoyment of life. It is quite consistent to deprecate the vices and follies which are ever associated with our craving for new possessions, while we observe the benefits resulting from it. Throughout that the world good and evil are found side by side; but the good, as we would fail believe, preponderates.

When once it is admitted that men are to decently housed and clothed, and an income is to be obtained to enable them to live comfortably as they can obtain, it is clear that the more easily they can obtain them, and the more generally such possessions are enjoyed, the more completely are the objects of civilized life secured. If all men could obtain them easily, there would be no poverty, and essentially less vice. Machinery, by diminishing the amount of labour required for the production of commodities, lowers their price and renders them more universally accessible to all classes of society. Working-men no longer toil for the rich alone, but they participate in the results of their own industry. If they desire such luxuries, 'purple and fine linen' are not beyond their reach; and their sons and grandsons are more commodious and often better than were the houses of the rich three centuries ago. If this increased facility of acquiring the comforts of life had been accomplished by greater profusion and frugality, we believe that the benefits derived from the latter would have more easily been appreciated, but the former is more readily, and is more splendidly shown by the improved condition of all the working classes of this country; but more money has been squandered by them in popinign spirits, within the last fifty years, than all the money the parents of the rich men of that time could have saved, and the money would have been more to the benefit of the state.

Cheap production is more beneficial to the poor than to the rich. The rich man is certain of gratifying most of his wants, but the poor man is constantly obliged to forego one enjoyment in order to obtain another. If his shoes or his coat be worn out, his dinners must be stinted perhaps until he can pay for a fresh supply; and thus, unless his wages be reduced in consequence of the cheapness of such articles, he is beyond all question that cheapness is an extraordinary benefit to him, the money which he saves in the purchase of one cheap article is laid out upon another, and thus, without privation, the demand that which his industry brings rain and misery upon the working classes. For reasons explained elsewhere (Demand and Supply, P. C. S.) a universal glut of all commodities is impossible; the more people, the more they have to offer in exchange, and their
wants are only limited by their means of purchasing. But particular commodities are frequently produced in excess, and a glut of the market ensues. In causing such gluts machinery is a powerful agent, but only in the same manner as all labour would be, if applied in excess. The results would be precisely the same. Too many men were employed in any department of industry; they would produce more than there was a demand for, and their goods would fall in value or be unsaleable. Commodities produced by machinery are subject to the same laws of production, and consequently to the same laws of supply and demand, as those produced by hand labour. Suppose that the soil of any isolated country were extraordinarily fertile and the population very small; but that without considering these circumstances the people were to cultivate the whole of their land and bestow upon it all their skill and labour. An excess of food would be the result—more than could be eaten within the year; much would be wasted or sold without profit, and much laid up in store for another season. The husbandmen would be disappointed at the unfor- tune results of their industry, but would they complain of the fertility of the soil? It would not be the soil that had caused their own misfortunes; and age it is with machinery, which like a fertile soil gives forth abundance: its capabilities are known and its advantages ought to be appreciated; but if its productiveness be brought into open competition with carelessness, it causes the evil (whose effect is not unknown) of glut.

The influence of machinery upon the production and consumption of commodities need not be followed any further. It increases the common stock of wealth in the world and carries the lessening of injurious competition, by increasing the quantity of human subsistence. But these benefits will be neutralized if, while it cheapens production, it has a tendency to diminish the means of employment for the people and the wages of labour—and this leads us to the second part of our inquiry: the advantage of such an influence may be estimated from the following facts:

In no trades has machinery been so extensively introduced as in the manufacture of silk. Indeed, the manufacture of silk, as Mr. M., has the population increased so rapidly as in the principal seats of those manufactories. Between 1801 and 1841, Manchester increased in population from 90,886 to 296,183, or 305.6 per cent; Leeds from 53,162 to 181,874, or 242.5 per cent; Bradford (York), from 6938 to 14,684, or 111.5 per cent; Huddersfield, from 2268 to 7268, or 225 per cent, and Wigan from 1202 to 3760, or 213.5 per cent. These results, however, are only the effect of the cotton trade, increased, in the same period, from 75,722 to 294,269, or 221.5 per cent; Leeds, from 53,162 to 181,874, or 242.5 per cent; Bradford (York), from 6938 to 14,684, or 111.5 per cent; Huddersfield, from 2268 to 7268, or 225 per cent; and Wigan, from 1202 to 3760, or 213.5 per cent. Thus far the manufacture of cotton, oil, wool, and silk. The seats of the iron and hardware trades exhibit similar results. In the same period of forty years Birmingham increased from 78,670 to 190,438, or 146.2 per cent; Sheffield, from 31,314 to 65,186, or 117.6 per cent; Wolverhampton, from 12,665 to 36,389, or 189 per cent; Merthyr Tydvill, from 7705 to 54,947, or 643 per cent; and West Bromwich, from 5685 to 26,121, or 265 per cent.

In this extraordinary ratio has the population increased in the seats of our staple manufactures, which by the aid of machinery have supplanted the whole world with articles wrought by hand. The interest of the late Dr. M. has been in these places with those agricultural counties in which machinery has exercised the least influence, and let us see if the absence of machinery has been equally favourable to the support of a large population. According to the above-mentioned investigation, Devon increased 55.3 per cent; Somerset, 50 per cent; Norfolk, 50.9; Lincoln, 78.5; Essex, 52; and Suffolk, 49.6 per cent. The average increase of these six agricultural counties did not exceed 26 per cent. in forty years; while, setting aside the extraordinary increase exhibited in the particular towns already enumerated, the population of six manufacturing counties, viz. Manchester, Liverpool, York, W., Stafford, Chester, and Durham, including all the agriculturalists, increased 112.5.

These facts prove conclusively that machinery, so far from diminishing the aggregate amount of labour engaged in the trades in which it is used, increases it in an extraordinary degree. And not only does it give employment to larger numbers of persons, but their wages are considerably higher. We shall not attempt to compare the increased wages of an agricultural labourer with that of operatives engaged in the infinite variety of trades carried on in manufacturing towns, in connection with machinery: but it is sufficient to ask, whence has come the increase of wages? From machinery, and how can machinery, which has been comparatively insignificant if thousands had not been attracted to the towns from other places. And what could have induced them to leave their homes and engage in new trades but the employment offered by more certain employment and higher wages?

It has been shown that machinery has had a beneficent influence upon the employment of labour in the particular trades

MAC

in which it has been used, and it now remains to consider its effect on the general population. In the first place, a few of its obvious results may be noticed. For example, the manufacture and repair of machinery alone gives employment, directly and indirectly, to vast numbers of workmen, and an amount saved by the labour of these clerks, porters, and others, must find more employment. It is clear also, that while the manufacturing and commercial population are thus increased by the use of machinery, the cultivators of the soil must receive more employment in supplying them with food.

In this and other ways the general employment of labour is directly extended by machinery. At the same time the application of machinery to existing branches of industry creates new trades and distributes capital into other enterprises which afford employment for new descriptions of labour. A hundred examples of this fact might be cited; of which railways and steam navigation are amongst the most remarkable; but such examples will be superfluous if it can be shown that it is the necessary result of the use of machinery to apply capital to new enterprises. It has been said that machinery cheapens production by reducing the amount of labour employed upon it: it follows that a less amount of capital with the aid of machinery will produce as much as a larger capital without such aid. A portion of capital is thus dispensed, either for increased accumulations of that portion of capital which has been set free, or for new speculations. In some way it must be employed, or it will yield no profit, and in some form or other it must be ultimately expended in labour. As long as a person can extend the accustomed operations of his own trade with a profit, he is disposed to do so; but as soon as he finds them less profitable than other investments, he changes the direction of his capital, and seeks new modes of increasing his profits. There is no truth more certain than that an employment of labour is small or great according to the proportion which capital bears to the number of labourers. Capital is the fund which supports labour, and which must employ it or use productive; and, if in any country capital be increasing more rapidly than the population, employment will be abundant and wages high; if less rapidly, employment will be scarce and wages low. In the one case, capitalists will be bidding high for labour; in the other, labourers will be bidding against each other for employment. Accumulation of capital is therefore highly conducive to the interests of the labouring population generally, and the use of machinery is especially favourable to accumulation, as may be shown by a simple example. Suppose a man to have a capital of 10,000/, which he is expending annually upon labour in a particular trade in his native city; and suppose wages to be 500/ a year. Each year his whole capital is expended, and he makes as much of new accumulation as he has not employed. If he had an additional machine which should cost 5000/, and the 10000/ be still expended in labour, he may be said to have saved one half of his entire capital in a single year; for instead of spending the whole of it as before, in labour, he is possessed of a durable property which, at a small annual cost, will last for ten or probably twenty years. Nor can it be said that this saving is effected at the expense of labour; for the owner of the machine is placed in the same position in respect to his profits, which prevents him from securing to himself the difference between the amount paid now and that previously paid for labour. To gain a profit of ten per cent. it had been necessary for him previously that the profits should be at least 11,000/ annually, being his whole capital and the profits upon it: but now, in order to obtain the same profit, it is sufficient if he realize 5000/ only: vice versa, 5000/ profit upon his 10000/ invested in the 10000/ machine is as productive as ten per cent. of the whole 10000/. For some time he will most probably obtain more than ten per cent. profit, and so long as he is able to do this, his means of accumulating fresh capital in addition to his machine will extend the employment of labour not only upon local additional trade. But when his profits had been reduced to their former rate by competition, society has gained in the price of his goods 4500/ a year, being the difference between labour of 11,000/ being realized by 11,500/, and 5000/ at present. But is this amount thus gained by society lost to the labourer? Unquestionably not. As a consumer, he participates in the advantage of low prices, while the amount saved by the manufacturer of machinery must be extended upon others which can only be produced by labour. It cannot be too often repeated, that all capital is ultimately expended upon labour; and whether it be real, in the sense of the accumulated capital of the manufacturers, or as an indirect expenditure in the small portions throughout the community, directly or indirectly it passes through the hands of those who labour. If a manufacturer accumulates by means of higher profits, he employs more labour. If the profits of the poor man, who employ less in the community, they employ more labour in other forms. So long as the capital is in existence, it is certain to have an influence upon the general market for labour.

We are now speaking not of the interests of particular workmen whose temporary sufferers caused by the use of machinery we have already adverted, but of the general and permanent interests of the working population of a country. As regards these, the statistics of British industry fully confirm all reasoning from principles, and prove beyond a doubt that machinery has had a beneficial influence upon the employment and wages of labour. Any one who will reflect upon the facts which have been before us, as well as those given by the Census [Census, P. C. S.], can scarcely fail to arrive at the conclusion that without machinery England could not have supported her present population, or could only have supported it at the expense of the comforts and comforts of those who labour. In other words, the whole wages of the country and the social causes, which are intimately connected with it; were it not for the operation of machinery, would have been of such a nature as to have debarred the masses of the society it would be out of place, at present, to inquire; but enough has been said to show, that machinery by increasing production multiplies the sources of enjoyment, and places them within the reach of a greater number of persons; and 2dly, that by giving increased employment to labour it enables more persons to enjoy those comforts which it has itself created. These are the elements of social prosperity, and if evils have been seen in the past, it is because we have not understood that machinery is not machinery which has caused them. Whatever the influence of machinery has been felt, wealth has advanced with rapid strides; and though in too many cases religion, virtue, and enlightenment may have lagged behind, the tardiness of their progress is to be ascribed, not to machinery, but to the frailties of institutions of men.

MACKENZIE, HENRY, was born at Edinburgh in August, 1745. He was the son of Dr. Joshua Mackenzie, a physician in extensive practice and of literary habits. His mother belonged to an ancient family in the county of Nairn. He was educated at the high school and university of his native city, and in 1762 entered the Scottish Court of Exchequer, a department of law-business which is now all but extinct, and which even then was extremely limited, and conducted by a very few practitioners specially appointed for the purpose. He held this office for about two years. To the former Mr. Mackenzie contributed forty-two papers; to the latter fifty-seven. Among these are his small novels, such as The Story of La Roche, and a kindly kindred, and a very few that drew the attention of Walter Scott to German literature. The Highland Society likewise published in their Transactions an address of Mr. Mackenzie to the ocassion of the Omeiotic Controversy. In 1783 he published the first edition of the works of the blind poet Blacklock, a memoir of the author; and a Life of John Home, the author of Douglas.
which he read to the Royal Society of Edinburgh in 1812, was afterwards prefixed to an edition of Home's works, and also published separately. Mr. Mackenzie himself wrote several plays, which are more remarkable for refinement of feeling, than for dramatic force or effectiveness. The collected edition of his works contains three of these: 'The White Hypocrite,' a comedy, which was once performed at Covent Garden; 'The Spanish Father,' a tragedy; and 'The Black Bird,' which had declined to bring on the stage on account of the harrowing nature of the catastrophe; and 'The Prince of Tunis,' which had been acted at Edinburgh with much applause in 1778, and printed separately the same year.

The work, when published in 1808, was written for a political writer. His most elaborate work of this sort was 'An Account of the Proceedings of the Parliament of 1784,' which was revised and corrected by Mr. Pitt's own hand; and he published some anti-jacobin tracts at the time of the French Revolution. The merit of these services to the government, set forth by his friends Lord Melville and Mr. George Rose, procured for him in 1804 the place of comptroller of taxes for Scotland, an office of large emolument, but considerable labour and responsibility, which he held thenceforth till his death.

In 1806 he edited a complete collection of his literary works, in eight octavo volumes; and this was almost his last contribution to literature. 'The old stump,' as he himself once heard to say, 'would still sometimes send forth a few green shoots; but his official duties occupied much of his time; and the romantic fervour of sentiment, which had possessed his imagination, was to proved a way to provide the habits of thinking and feeling, such as a man of business may unite with literary tastes and with a fondness for literary amusement. Indeed that tendency to stickly refinement, which characterised his prose compositions, and novels, indicated the want of the vigour of mind essential to success in the highest walks of literary invention; and he is not the only case in which genius of this cast has put forth all its strength in youth, and been overtaken by the currents of life.

Accordingly, for many years, Mr. Mackenzie's leisure was spent either in the society of literature and other friends, or in shooting and fishing, sports to which he was particularly addicted. He had in youth breakfasted with Dr. Johnson, and who had enjoyed the friendship of Blair and Robertson and Adam Smith, lived to see one generation after another, and revolution after revolution in the phenomena of literature. He had married the daughter of Sir Lodovick Grant of Grant; and by this lady he had eleven children, one of whom has long been a judge in the Supreme Court of Scotland. Henry Mackenzie died in Edinburgh on the 14th of January, 1819, in his eighty-fourth year.

MACROCHEILUS, a genus of Fresh-water Fishes, proposed by Prof. UX tollis (Polichas Fossilis of Denison) to include several species which occur in the Devonian and Carboniferous strata.

MACROPOMA, a genus of fossil fishes proposed by Agassiz: the species belong to the cretaceous strata.

MACROSTOMUS, a genus of fossil fishes proposed by Agassiz. From the odontol.

MADNESS. [Iskallit, P. C.; Lunic and Lunicum Attics, P. C. S.]

MAECIUS, LUCIUS VOLUSIUS, a Roman jurist, who lived in the time of Antonius Pius and Marcus Aurelius. He was one of the legal advisers of Antonius (Capitolinus, Antonius, Pius, 12), and one of the instructors of Aurelius in law (Capitolinus, Art. Philosoph. 3). He was held in high estimation by Aurelius, as appears from a Rescript of the Divi Fratres, in which he is styled their friend and a most careful student of the Civil Law (Dig. 37, tit. 14, s. 17). He was also a friend of the jurist Julianus (Dig. 35, tit. 2, s. 1, 6). Both were ordered by the imperial governor of Alexandria by Aurelius, for Vulcanius Gallicanus, in his life of Avitus Casius (c. 7), mentions a Maccius who was put to death there by the army for joining in the rebellion of Avitus. Certain writings of Maccius which are mentioned in the Florentine Index are sixteen books on Fideicommissa, and fourteen on J udicia Publica. There are 44 excerpts from Maccius in the Digest. His Libri Quasi- testamenti (Digest 27, tit. 5, s. 8, and commentary, or something of the kind, on the Lex Rhodia de Jactu (Dig. 14, tit. 2, s. 9). Maccius is cited by Tapiamnus, Ulpianus, and Paulus.

An extant treatise, De Asse et Ponderibus, is supposed by some writers to belong to another author of the same name.

MAGIC LANTERN is a species of luminescent microscope, its object being to obtain an enlarged representation of objects placed in its field of view. This apparatus is generally placed in a darkened room, by means of the pencils of light issuing from a lamp or candle and passing through a convex lens.

The instrument consists of a lantern, generally of tin, and of a cylindrical box, provided with a small rectangular opening, and at a perforation in one of the sides is applied a tube projecting horizontally from it. Immediately before the aperture, and within the tube, is a glass lens, often nearly a hemisphere in diameter, serving to condense the light which proceeds from the lamp both directly and by reflexion from a concave mirror attached to the side of the lantern which is directly opposite the aperture: this tube carries within it another, which is also provided with a convex lens, and is capable of a small movement for the purpose of adjustment.

A groove in front of the lantern and parallel to that front receives a rectangular frame containing the glass plates on which are painted, with transparent colours, the objects of which an enlarged view is to be obtained: and, as the amusement of young persons is chiefly intended by the exhibition, picturesque figures are usually those which are represented. Instead of a single convex lens, the sliding tube is sometimes provided with two such lenses; these are placed at a little distance from one another, and have between them a perpendicularly placed convex lens, or pair of lenses, of such a focal length that the rays in each of the pencils which proceed from the object may unite on the screen and thus produce the enlarged representation of the object.

Several figures are usually drawn on the same plate of glass, and the plate is capable of being moved by hand in the groove so that the different figures may be brought successively into the same position: thus can be exhibited various scenes relating to one subject, which is generally some absurd fiction. Persons who make their occupation to exhibit the magic lantern very frequently give, with the representations, descriptions of the objects on the screen; and these being expressed in a peculiar jargon, and in a certain degree to the amusement of the company: they frequently also, for the purpose of heightening the effect, give, by a simple\n
work, motions to the figures which are painted on the plates of glass.

This ingenious toy, as it may be considered, is said to have been invented by Kircher, in the seventeenth century, and it is described by him in his 'Ars Magna Lucis et Umbrae.' The celebrated Euler proposed to substitute for the lens in the magic lantern a concave mirror, perforated in the middle like that of a Gregorian telescope, and placed in the interior of the lantern with its polished surface towards the light and its convexity towards the object. The light was supposed to pass through the aperture in front of the lantern so as to fall on the screen; and which was reflected from the concave mirror, after falling upon one with a plane surface, was from thence to be reflected in a contrary direction upon the object. The rays in the pencils proceeding from the object were to pass through a lens in the tube, as in the former construction; and, by converging with greater accuracy to points on the screen, they would have produced a more correct image than that which results from refracted light alone.

A remarkable improvement in the manner of employing the magic lantern was first exhibited in London in the year 1802, a machine being exhibited which serves for general purposes; and the sliding tube which carries the fattest lens has a greater range of motion. The objects to be exhibited are painted upon a glass plate, which is at a proper distance from the machine. When the machine is placed upon a stage which is capable of moving on wheels in a direction perpendicular to the screen on which the objects are represented.

The screen is usually made of muslin or gauze, and covered with varnish so as to be quite transparent: it is stretched in a vertical position across the theatre or apartment; and this being made quite dark, the spectators occupy seats arranged round the screen, which is illuminated by the light which is thrown upon it from the machine placed on the opposite side.

In any magic lantern when the tube carrying the lens which is farthest from the lamp is drawn out as much as possi-
albly, the magnitude of the image represented on a screen is the smallest; that image increases in magnitude in proportion as the tubes are diminished in length, or as the lens is brought nearer to the body of the lantern. It increases also in propor-
tion as the aperture on the screen is diminished; but the variations of the length of the tubes must, by the exhibitor, be combined with the different distances of the lantern from the screen, in order that by the just coun-
terbalance of the rays in each pencil, on the screen, the proper degree of distinctness of vision may be obtained under all the variations in the magnitude of the image.

Care is taken that during the exhibition all light shall be excluded from the lantern, and that the magneto-meter, which coincides with the central axis of the cylinder, a point which, in proceeding from the lantern, produces the image to be observed; and the screen being itself invisible, the specta-
cors can scarcely divest themselves of the idea that they are looking into a dark cavern, in which the objects, at first dimly visible as specks in its deepest recesses, appear to be gradually advancing towards them, increasing in magnitude as they seem to approach: after the objects have been some time ap-
parently in the immediate presence of the company, perhaps surrounded by a blaze of light, they seem as gradually to re-
tire, and at length they vanish, leaving the place in profound darkness. The effect of the exhibition is, moreover, heightened by the accompaniment of mournful or inspiring sounds, according to the character of the object, from musical instru-
ments disposed for the purpose.

Spectacles are frequently exhibited in this manner; but occasionally the lights and the background, care being taken that the personsages are shown; and the illusions produced have caused the name of Phantasmagoria to be applied to the apparatus.

MAGISTRATE, a word derived from the Latin mag-
istratus, which contains the same element as magnus and ma-
gistratus, and signifies both a person and an office. A Roman
magistraturis is defined to be one who presides in a court and
declares the law; that is, a judge. The kings of Rome were
probably the sole Magistratibus originally, and on their ex-
pulsion the two consuls were the Magistratibus. In course of
time other offices were created; and those who filled these offices were elected in the
forms prescribed by the constitution, and they had juris-
dictio. [Jurisdiction.] The original notion of a magistra-
tus, then, is one who is elected to an office, and has juris-
dictio.

In England the term magistrate is usually applied to
justices of the peace in the country, and to those called police
magistratibus, such as are there in London. It has also been
applied in other ways; for instance, people have sometimes
said that the king is the chief magistrate in the state. But
these applications of the term do not agree with its proper
description, which is given to the judicial powers under
which assembled, and so far as it differs from a justice of the peace; he also exercised delegated
power in his jurisdiction, in which respect, as well as being
elected, he differed from the king of England, who is not
elected but appointed to the delegated jurisdiction, but
depends jurisdiction to others.

MAGNETISM, ANIMAL. [Animal Magnetism, P.C. and F.C.S.]

MAGNETOMETER is the name given to a magnetized
bar of steel, of considerable dimensions compared with the
needle of an ordinary compass, which is employed to de-
termine either the absolute amount of magnetic declination (commonly called the variation of the needle) or the resolved intensities of terrestrial magnetism in horizontal or vertical
directions. It has the names of declination magnetometer,
and vertical or horizontal force magnetometer, according to
the nature of the determination.

The declination magnetometer is of various sizes; for
general purposes it is from 12 to 15 inches long, 1 inch broad,
and 1 inch thick; but that which is mounted in the Green-
wich observatory is 2 feet long, 1 inch broad, and 1 inch
thick; the bar is placed so as to rest at the middle of its
length, within a sort of stirrup made of gun-metal, and this,
at its upper part, has a triangular aperture through which
passing, in order that it is applied, on a number of fibres of
untwisted silk, from 3 feet to 8 or 9 feet long, attached to the
middle part of the cylinder, passes over a pulley at the top of
the stand or near the ceiling of the apartment, and, afterwards
descending, passes through a graduated cylinder, from which
the bar may be raised or lowered; thus the bar is suspended in
a horizontal position, with freedom to turn on a vertical
axis till it rests in the plane of the magnetic meridian. The
whole apparatus is contained in a box of wood, in order to
protect it from the agitation of the air, glazed apertures
being provided for the purpose of allowing the observations
to be made.

In some constructions, near each extremity of the mag-
netic bar is a slidding frame of gun-metal; one of these
frames carries a small glass plate on which is a graduated
scale, and the other carries an achromatic lens, the focus of
which coincides with the scale of the first. By moving the
magnetometer placed at a certain distance in the direction of the
magnetometer the graduations on the scale may be observed
through the lens, so that the instrument becomes a sort of
magnifying glass. When the magnetometer coincides with the
wire in the eye-piece of the telescope, the absolute position of the axis of the bar and any variations in
its position may be observed.

The stand which carries the suspending fibres of silk gene-
 rally consists of two pillars of copper, firmly supported on a
stone base; and at the upper extremity the apparatus to
which the silk fibres are attached is connected with a hori-
tonial circle, graduated, for the purpose of determining the
value of any torsion which may exist in the fibres.

Previously to placing the magnetometer in the stirrup, a
bar of gun-metal, called a detorsion bar, equal in weight to
the magnetometer, and like it furnished with graduated
scale and lens, is suspended by the silk fibres; this is allowed
to vibrate till it comes to a state of rest; the angle which its
axis makes with the plane of the magnetic meridian is then
observed, and the difference between the angle of the bar from
it, is turned round on its vertical axis till the detorsion bar
is brought to that plane. Thus the torsion of the fibres
is nearly obviated.

In order to find the point on the graduated scale which
corresponds to the magnetic axis of the magnetometer, the
latter is placed in the stirrup; and, looking through the tele-
scope, the observer Remarks the graduation of the scale which
coincides with the vertical wire in the field of view: this
observation is made with the magnetometer in a reversed
position; and then half the sum of the numbers on the scale
with the axis, which is called the zero, is noted. The
directions of the readings converted into angular space (the distance of the tele-
scope from the scale being the radius) is the deviation of
the optical axis of the telescope from the magnetic meridian.
The telescope having a movement in azimuth, it must then be
turned through an angle equal to the deviation, and thus
brought into the plane of that meridian. The apparatus
would then be ready for use if it were not that some remains
of torsion may exist in the fibres and must be corrected
by means of the detorsion apparatus as before.

When it is required to determine the absolute declination,
the point which indicates on the scale the direction of the
axis in relation to the magnetic axis of the magnetometer,
and like it furnished with graduated scale and lens, is placed
in the telescope, and a correction made for any existing error
of collimation, the telescope is turned horizontally to some
terrestrial object whose azimuth from the astronomical
meridian is known. The difference between the axis of the
telescope and the angle through which the telescope was
turned will evidently be the required declination, or the angle between
the planes of the astronomical and magnetic meridians.

After the actual position of the magnetic meridian has been
determined as above, any deviations of the axis of the mag-
netometer from it, indicated by a different division of the scale
coinciding with the vertical wire of the telescope, will denote
a variation of the declination; but it is evident that such
development will be affected by the torsion induced in the silk
fibres in consequence of the angular movement of the magnet.

The correction due to this cause of error is to be found from
an experimental determination of the relation between the
force of terrestrial magnetism and the force of torsion: thus,
a magnetized bar being already in the plane of the magnetic
meridian, let the torsion circle be turned on its axis till it
coincides with the vertical circle and the angle of torsion,
and let the position of the magnetometer be observed
when it rests between the force of torsion thus created, by
which it is made to deviate from the meridian, and the hori-
nontal force of magnetism, by which it is drawn to the
meridian. Then, by mechanics, the force (M) of magnetism
is to the force (T) of torsion as the difference between the
angle of torsion and the angular distance of the bar from
the magnetic meridian is to the angular distance of the bar from
the magnetic meridian, which is equal to M as the given angle of torsion is to the difference
between that angle and the distance of the needle from
the meridian. The last ratio being obtained from an experiment,
The suspended bar being in equilibrio between the forces of torsion and the horizontal force of magnetism, it is evident that if the former force be computed, the latter will be obtained. In order to determine the variations of the horizontal force by the observed deviations of the bar from its mean place the following formula is employed:

\[ \frac{dF}{F} = -\cot \theta \, \varphi \, d\phi, \]

in which \( F \) is the absolute horizontal force, \( dF \) its variation, \( \varphi \) the angle between a vertical plane passing through a line connecting the two extremities, and a line passing through a line connecting the lower extremities of the two parts of the suspending line; \( d\phi \) is the observed deviation of the axis of the needle from its mean place, and is expressed by the length of an arc in terms of the radius. \( \frac{dF}{F} \) evidently gives the variation of the horizontal intensity in parts of its absolute value.

The vertical force magnetometer is a magnetized bar which is crossed in the middle by a short axis perpendicular to its length, and has its lower part, on each side, reduced to an edge. This knife-edge, as it is called, is passed nearly through the centre of gravity of the bar, and rests, on each side of the bar, on an agate plane; the whole is supported on a short copper pedestal, which rests on the base of the instrument. For the adjustment of the bar, a small arm is attached with a screw, which acts as a weight: that which is attached to one arm is parallel to the magnetic axis of the bar, and by moving it backwards or forwards the bar is made to assume a horizontal position: the other is in a vertical position, or at right angles to the magnetic axis; and by moving it upwards or downwards the centre of gravity is made to coincide with the knife-edge. The whole apparatus being capable of being turned on a vertical axis, so that the bar may be placed in any azimuth with respect to the magnetic meridian.

In some constructions of the instrument there is attached to each extremity of the bar a ring of copper carrying two wires at right angles to one another; a line joining the intersections of the pairs of wires should be parallel to the magnetic axis of the bar, and the deviation, if any there be, is determined by observing the intersections on a scale in a microscope, which is fixed on a support near each extremity of the bar; the latter, while at right angles to the magnetic meridian, being for this purpose placed successively in a direct and a reversed position. Half the difference between the readings on the scale is the value of the error.

In order to put the magnetized bar in any required position, a brass plate with some dimensions m is attached to the bar, and provided with knife-edges, is made to rest on the agate planes, and is brought to the magnetic meridian by means of a magnetized needle which turns on a pivot at the top of the bar. A thread wound on the bar is then passed through the telescope, which is fixed to the side of the bar, and the telescope is turned till the cross wire in the field of view bisects a distant object; the telescope is then turned horizontally through an angle equal to the required azimuth in which the magnetized bar is to be moved, but in a contrary direction, and lastly the stand carrying the whole apparatus is turned round horizontally till the telescope wires again bisect the object. The bar will then be situated in the required azimuth.

When the variations of the vertical intensity of terrestrial magnetism are to be observed, the interval between a fixed wire in the microscope and the apparent place of the intersection of the line passing through the magnetic axis of the bar which is applied to the opposite side of the apartment; and, the telescope being directed to the mirror, in proportion as the magnetic needle shows more or less from the meridian, the number which on the scale appear in coincidence with a wire in the telescope increase or diminish. Thus the variations of the horizontal intensity are obtained.

The instrument is held nearly perpendicularly to the magnetic meridian by the force of torsion in the two halve of the skin of silk by which it is suspended: these parts are each about 8 feet long. An oblong ring of copper, which entirely surrounds the magnetized portion of the instrument, is furnished with two rings which on the scale appear in coincidence with a wire in the telescope, and diminish. Thus the variations of the horizontal intensity are obtained.

of the bar. A scale is affixed to the opposite wall of the apartment, and the mirror reflects it to the eye of the observer, who, looking through a telescope, reads the division of the scale which appears in coincidence with the wire in the field.

The building containing the magnetic instruments at Greenwich is in the form of a cross on the plan; two of the walls are parallel, and the two others perpendicular to the magnetic meridian. The declination magnetometer is in the south arm, the horizontal force magnetometer in the east, and the vertical force magnetometer in the west arm of the building; both of these bars are perpendicular to the magnetic meridian. Three telescopes are placed in such situations that they may be pointed to each other, and thus make his observations on the three magnetometers nearly at the same time.

Magnolia, a genus of plants named in honour of Pierre Magnol, who was Professor of medicine and prefect of the botanical garden of Montpellier. He was born in 1638, and died 1715. He gave an account of the plants growing wild about Montpellier, in a work entitled 'Botanicon Mon-tpellensae; seu Plantarum circa Monspelium nascentium Index,' 8vo., 1686. This work was illustrated with plates, as well as one published in 1689 with the title 'Prodomus Historiae generalis Plantarum in quo Plantae per Familias distinctae sunt, Observationes in singulas, et Systema a me inventum et a me exhibita,' fourto, in which he described the trees of his own. In another work embracing the plants growing in the Montpellier garden, entitled 'Hortus Regius Montpel-11,' he has described the trees according to the system of Linné.

The genus Magnolia is the type of the natural order Magnoliales. It has a calyx of 3 deciduous sepals that resemble petals; the corolla is composed of 6 to 9 petals; the stamens and pistils numerous; the carpels are disposed compactly in spikes, opening by the external angle, 1-2-seeded, permanent; the seeds baccate, somewhat cordate, pendulous, hanging out beyond the carpels by a very long unilh shaped white thread. The species are arranged in 2 groups, the first with alternate, stipulate, deciduous, or evergreen simple leaves, and large terminal solitary odoriferous flowers. They are all natives of North America and Asia.

M. grandiflora, commonly Called Magnolia, or Laurel Bay, is an evergreen tree, reaching sometimes a height of 70 feet. It has oval-oblong coriaceous leaves with the upper surface shining and the under surface rusty; the flowers erect, with from 9 to 12 petals expanding. This plant is one of the tallest and handsomest trees of North America. It has large pale-green shining leaves nearly 10 inches long, with large white flowers. It has been cultivated in England for the last century, and there are now, in all the better ordered gardens, 15 to 20 of them. Several varieties of this species have been named and described. Amongst the most constant and best known varieties are: 1. M. g. obesa; 2. M. g. Eschmennia; 3. M. g. americana; 4. M. g. purpurascens. The last is found in the Carolinas by the name of the Big Laurel; the second is the Exmouth Magnolia; the third and fourth are varieties which have been produced in France.

M. glauca, deciduous, or obtusifolia, is an almost odoriferous plant, with obtuse elliptical leaves, glaucous on the under surface; the flowers from 9-12 petalled, contracted; the petals oviolate, cuneate. This species is a tree rising from 15 to 20 feet in height. It is a native of New England, in low moist swampy ground at a little distance from the sea, from Massachusetts to Florida and Louisiana. This plant is also cultivated, and a number of varieties have been described. The bark has a bitter and aromatic odour resembling cassia. On this account it has been used in America as a substitute for other aromatic hitter barks as Cascara, Cassia, &c., and is said, with great success. Although not much used in Europe, it is said to possess many medicinal properties. It is used in the treatment of rheumatism, ague, and remittent fever have been given. All the species of Magnolia possess more or less the properties which are most evident in M. glauca. When used, a tonic effect is produced, and colds, or colds connected with them, are equally alleviated. It is said that when the tincture is made from the leaves and stems whilst green, it is more efficacious. In America this tree is known by the names White Laurel, Swamp Laurel, Swamp Sassafras, Sweet Bay, and Beaver-tree. The last name is given to it on account of the fondness of the beaver for it. The flowers are of a cream colour and have a sweet scent, which Keissberg states should be smelt at a distance of 100 miles. The flowers are followed by red berries, which give the tree a handsome appearance. The berries are steeped in brandy and used as a domestic medicine for various complaints.

M. umbrella is a deciduous tree with lanceolate spreading leaves, the adult ones smooth, the younger ones pubescent underneath; the petals 9-12, exterior ones wanting. It is a native of North America, from the Carolinas to Virginia, and New York. The leaves are 1 to 2 feet long, placed at the ends of the branches in a circular manner, somewhat in the form of an umbrella, from which circumstance it has been called the Umbrella-tree. The wood is soft and spongy, and on the mountains of Virginia is called Elmwood.

M. acuminata, a deciduous tree with oval acuminate leaves, the under surface pubescent, the flowers with from 6 to 9 petals. It is a native of North America, from Pennsylvania to the Carolinas. The flowers are large, 3 or 4 inches in diameter, of a yellowish colour, mixed with faint blue or green, but not remarkable for their beauty. The fruit is about three inches long, and it is supposed that the name 'acuminata' was given because of its resemblance to the cucumber-tree, whence in America it is called Cucumber-tree. A tincture is made of the fruit, and is used in cases of rheumatism. Several varieties of this plant have been described. It is often used in the London nurseries as a stock on which to graft the other species.

There are several other species of this magnificent genus found in the forests of North America, all of which are valued in Great Britain for ornamental cultures. Of the best known of these are M. cordata, the heart-leaved Cucumber-tree, with yellow flowers streaked with red, and having a disagreeable odour; and M. auriculata, Indian Physic, or long-leaved Cucu- mber-tree, having white flowers and a bitter bark, which is used as a medicine by the Indians.

M. Yulan, or conspicua, a deciduous tree with obvate abruptly acuminate leaves, the younger ones pubescent, expanding after the flowers, the flowers 3 to 6 petals, the styles erect. This plant attains a height of 30 or 40 feet in its native country, but reaches only 8 or 10 feet in our gardens. It grows in China, where it has been cultivated since the year 627. Its native name is Yulan. It is a very showy tree, having white flowers sometimes suffused with purple, which give out a most delicious perfume. It blooms in this country from February to April, and is distinguished from M. glauca, the common Magnolia, by the number of its petals. It is not so quite so hardy as the American species; still, unless the weather is unpropitious, it will put forth an abundance of blossoms during the dreary months of February and March. The flowers smell very strongly, and make a very fine shrub, with obvate acute reticulately-veined leaves, almost smooth; the flowers erect, of 3 sepals and 6 obvate petals; the styles very short. This plant is a native of Japan, and seldom attains a height of 10 feet. A petal of this tree, when bruised has an aromatic odour. The flowers are more or less purple without, and always white within. It is a very ornamental species and worthy of cultivation. The best situation for it is against a wall, when its branches will reach from 15 to 20 feet.

In their cultivation the hardy kinds may be treated in the same way as M. grandiflora. The Chinese kinds are often planted or hedged on M. obesa. When the plants are replanted after layering or propagation by seed, neither the roots nor leaves ought to be cut off, otherwise they will not succeed so well.

(Door, Gardner's Dictionary; London, Encyclopaedia of Trees and Shrubs.)

MahaDeya. [Siva, P.C.]

Mahmud II., Sultan of Turkey, the younger son of Sultan Abdü'l-Hamid, or Ahmed IV., was born on the 14th of Ramazan, A.H. 1199 (the 20th of July, A.D. 1785), and succeeded his elder brother, Sultan Mustapha IV., on the 28th of July, 1808. He has been shown (Turkey, P.C.) how very agreeable Sultan Selim, the uncle of Mahmud, was disposed and imprisoned in 1807 on account of his civil and military reforms, and that Mustapha had no sooner succeeded him than he abolished the new institutions of Selim, especially the Nizam ed-Daulah, or the Constitution of 1789, into which the European principles. Mustafa Raimkar, pasha of Rusejik, Vol. I. 2 L.
an old friend of the deposed Selim, strongly objected to the policy of Sultan Mustafa, and no notice being taken of his remonstrances, he assailed his head. The sultan, who thought that by removing the object of his revenge, he could the more easily crush it, was assassinated by order of Mustafa, who, it is said, foretold his nephew's future elevation, and initiated him in those principles of reform through which he had endeavoured, though in vain, to reunite Turkey. Mustafa was also imbued with that deep hatred of the Janissaries which was one of the leading principles of his future actions. Mustafa ascended the throne when Turkey was in a violent political and social crisis. In consequence of the enlightened but weak government of Selim the prejudices of the people were aroused without meeting with a power sufficient to keep them down; the sultan's authority was disregarded by the pashas of Europe, Asia, and Africa; and the Janissaries, who were exasperated through Selim's attempts upon their privileges, were ready instruments in the hands of those agitators who looked upon the deposed Sultan Selim, or the deposition of Mustafa, as, at first secretly, then openly, sowing the seeds of discord. In spite of this threatening state of the empire, Sultan Mahmud boldly proclaimed that he would carry out the reformation of Selim, and by choosing Mustafa Bailraktar his grand vizir, he proved that he was not using idle words. Several pashas who were severely punished for disobedience were the first to perceive that the sultan was governed by principles more enlightened than Selim. When the turn of the Janissaries came, they broke out in open rebellion, and besieged Mustafa Bailraktar, whom they believed to be the originator of the reforms, in his fortified palace. Unable to hold out longer, and receiving no relief from the sultan, who was himself assailed by the rebels, the gallant vizir blew himself up. Mustafa was proclaimed sultan, and the rebels cried out for the head of Mahmud. In this critical position Mahmud did a deed at which humanity shudders, but which was one of the boldest political strokes ever attempted by a Turkish sultan: he ordered his captive brother to be strangled together with his infant son; and though ten thousand men not a month old were pregnant, four in number, were sewn up in leather sacks, and drowned in the Bosphorus. These murders Mahmud became the only male descendant of Osman. He was an unhappy prince. Yet he had no higher thought than the glory of Turkey, and he made his existence depend upon his own, for with the death of the last of the house of Osman, the empire of Osman would have become a prey to anarchy. The very fact, however, of his being the only descendant of Osman, was a sort of guarantee for his life, for although the people had massacred more than one sultan, and the sultans themselves had shed the blood of more than a hundred royal princes, these crimes were committed against individuals and not against the reigning family, the popular belief being that Turkey would last no longer than the family by whose great ancestor the empire was founded. Mahmud was fully aware of this when he sacrificed his brother and his brother's children, and we may fairly presume that his object was to make himself the only representative of the founder's family.

Mahmud succeeded in crushing this bloody rebellion after a struggle of two days, and having conciliated the Janissaries by abolishing the Nizam Jedid and establishing his authority at home, he turned his attention to his relations with the European powers. He had just broken out. The Turks were defeated; Constantinople was in danger; the principal pashas in Asia, Africa, and Europe threatened a revolt or had revoked; and Czarina George raised the standard of independence in Servia. Mahmud, although desirous of peace, was forced to make peace by the growing war, and he was encouraged to do so by French diplomacy, for a war between France and Russia was imminent. That war broke out in 1812, and Constantinople became the centre of European intrigue, Russia and Great Britain being active in making peace acceptable to the sultan, while Napoleon made the great mistake of not keeping his word. The Russians had conquered Northern Turkey as far as the Danube, Mahmud could fairly hope that the Russian army would soon be compelled to evacuate the Turkish territory, and he would perhaps have continued the struggle, had the strong remonstrances of England, which were backed by a large fleet in the Mediterranean, been successful. Under these circumstances he made peace with Russia at Baku, on the 28th May, 1812, on conditions not favourable to him than the unfortunate turn of the war allowed him to expect. He lost only that part of Moldavia which lies east of the Pruth, which now became the frontier of the two empires, and a few districts in the Caucasus; while the Servians, abandoned by Russia, were obliged to submit once more to the Turkish yoke. Mahmud would perhaps never have waged war with Russia, but for the certainty that Napoleon had abandoned him, by a secret article of the treaty of Tilsit, to Tsar Alexander, and the exorbitant demands which Russia made upon him in consequence of the Czar's friendship with Napoleon. The Russian army thus disengaged immediately set out to execute the resolution of Mahmud, whom he had told of the news of the peace of Baku, for he had been outwitted by a prince whom he used to call an ignorant barbarian. Mahmud availed himself of the peace to continue the work of reform which Selim had attempted, and which his friends Berber Bashi and Khalet Efendi. He succeeded in keeping down the rebellious spirit of the pashas of Baghdad, Damascus, Widdin, and Silistria; and he received good news from France, for Napoleon, who had promised the return of the Crimea, was about to make a new campaign, and would rouse the Turks of the Bosphorus, who had seized it. His attention was chiefly directed to 'Ali Pasha of Janina, whom he watched with great suspence, being convinced that sooner or later that great feudatary would make a hostile movement against England, and that the Turks would be no longer an object of confidence. His conduct towards 'Ali Pasha was signalized by that mixture of craft and frankness which is so striking in the character of eastern nations; and while he deprived the sons and grandsons of the founder of the empire of their wealth and hereditary rights, he still professed to be a friend of 'Ali himself, till the moment came for enmaring and crushing him. The downfall and death of 'Ali Pasha, in 1822, seemed to promise a harvest of future success to the sultan. But Turkey's enemies were like the hydra; the more heads fell the more foes rose; and no sooner was 'Ali's head exposed on the gate of the seraglio, than Mahmud had to prepare for a contest with Russia, a deadly struggle with Mehemed 'Ali of Egypt, and an open rebellion of the Greeks.

The Greek revolution began first. The attempts of Alexander Ypsilanti in Wallachia, and of the Greeks of Constantinople, who, having escaped from their Turkish fleet, were easily frustrated; but the insurrection in Greece compelled the sultan to make the greatest efforts. Unable to quell the rebellion with the forces under his immediate command, Mahmud, with professing Mehemed 'Ali's promise that he should be invested with Candia as soon as the object of the campaign was attained. An Egyptian fleet, with an army of 12,000 men, commanded by Mehemed 'Ali's son, Ibrahim, the conqueror of the Wahabis, sailed for the Peloponnesus, and the combined Turkish and Egyptian forces committed those atrocities which roused a cry of indignation throughout Europe, and induced Great Britain, France, and Russia to interfere on behalf of the unfortunate Greeks. Mahmud, bent upon crushing all rebellion within his dominions, and making himself equally respected by both his Turkish and Christian subjects, declined any interference, and the three powers entered into an alliance by the convention of the 7th of July, 1827. They proposed that Greece should be a vassal state of Turkey, and should acknowledge the sultan's suzerainty by paying an annual tribute. The Greeks promised to submit to that condition, but the sultan's proposition was rejected. Upon this the combined British, French, and Russian fleets attacked the Turkish-Egyptian fleet in the bay of Navarino (20th of October, 1827), and the idol of Turkish pride, 'Ali Pasha, who had died in Mehemed 'Ali's arms, was sunk. Mahmud, who had always made peace with his enemies, now turned to his adversaries. A French army now landed in the Peloponnesus, Ibrahim Pasha evacuated the country, and Greece, without being independent, was left free from Turkish invaders.
MAH

holy war against Russia, well-knowing that the insurrection in Greece was in a great measure the work of the Czar. Before, however, we proceed to the Russian war, it is necessary to speak of the destruction of the Janissaries.

Mahmud accomplished this the greatest of his measures at a time when his dominions were riddled with a thousand abscondions and by the interference of the three powers in the Greek insurrection. At this time he proceeded so openly with his reforms as to leave no doubt of his firm intention to overthrow the existing state of things with the utmost pertinacity and to establish a new and more stable state of things. He had musical and theatrical entertainments performed in the seraglio; he dressed in the fashion of Europe, and abandoned the sacred turban for the fez; and, to the astonishment of his own subjects, he was known to have conferred orders of the most exalted description upon other Nizam Jedd, or Azaiîr Mahmudzey, as he now chose to call those troops. When he signed that order he had likewise resolved to destroy the Janissaries, who did not allow him to wait for an occasion to begin the contest. On the 15th of June, 1826, the sultan and the grand vizir being then in the country, a strong body of Janissaries, reinforced by a crowd of the worst characters, met at their great barracks, the Et-Medîdan, and thence marched in battle array to the palace of the grand vizir, which they took and burnt after a feeble resistance on the part of the domestics, who were cut to pieces. The vizir's women escaped by hiding themselves under the walls. The heads of the grand vizir and the vizier hastened to Constantinople as soon as he had heard of the riot, informed the absent sultan of the event, assembled the divan, and concurred in round the seraglio all the troops that he could raise, and paid with the Nizam Jedd I will we have the heads of all those who advised the sultan to introduce new institutions! soon reached the ears of the [.] 1 The vizir, 'Abd al-Khâ近视, or the meraggers of the seraglio. Thither crowded the 'ulems and the students, the marines, the sappers, and the officers of the artillery with their guns, all ready to shed their blood for the sultan and his reforms. Encouraged by the presence of so many adherents, the grand vizir sent an answer to the rioters, that he would not satisfy their demands, but would repel force by force. The Janissaries were propitious to an attack upon them, when he the 'Arrâf of Kadhînah, or the Janissaries in a small boat from his country-seat at Beshik Tash, on the Asiatic side of the Bosporus. Fully aware of the danger of his position, he harangued his troops, and declared that he would put himself at their head and attack the rebels, but having been dissuaded from this resolution he sent the grand vizir with a body of troops to the mosque of Sultan Ahmed, which was to be the chief meeting-place of the sultan's party, and contented himself with encouraging his men from a kiosk on one of the outer walls of the seraglio. On his order the muti unfolded the 'sanîjak sherriff, or the standard of the prophet, and hundreds of 'chachâs,' or cries, dispersed themselves through the streets of the city. The sultan, accompanied by M罕medzey, proceeded to the Et-Medîdan to rally round the holy standard, and to defend the throne and their religion against a mob of impious rebels. An immense crowd soon gathered round the seraglio, and no sooner had the Janissaries seen the troops of the sultan than they dissolved the detachments which the Janissaries had placed in all the streets leading to that mosque, for the purpose of isolating the grand vizir. At the sight of the holy standard the Janissaries concentrated their forces in the square, round the Et-Medîdan, and threw up entrenchments. Ilseâz Pashâ, Ibrahim Pashâ, and Mohammed Pashâ, who summoned them by order of the sultan, to lay down their arms, were received with a terrible shout and narrowly escaped assassination. They were strong enough, they said, to defend themselves till the evening, and the coming night would bring destruction upon the reformers. Two thousand houses in flames were burnt, and the shouts of the crowd were heard with a loud voice the first chapter of the Korân, the 'Al-Fâtihat,' the shortest chapter of the Korân, which is held in as much veneration by the Mohammedans as the Lord's Prayer by the Christians. The men of the sultan's party, who had proved most loyal under such trying circumstances he founded a new order, the Nîshûf Istatb. In 1821 hostilities commenced with Mahmud 'Ali, Ibrahim Pashâ having made war against the Pashâ of Egypt. It was now the first time that there was open war till 1832, on Mahmud 'Ali's refusal to withdraw his troops from Syria. The declaration of war took place on the 16th of June, 1831, and on the 26th of July Ibrahim defeated the Turks at Hems; and on the 4th of December he obtained the splendid victory of Koniah, in consequence of which the Turkish army was disbandd, and the Egyptians advanced upon Constantinople, the power of the European powers effected a truce; but in spite of it Mahmud pushed on and occupied Brusa. The ruin of the sultan seemed to be inevitable. He was saved by his greatest
enemy: a Russian fleet appeared off the Bosporus, and opposite Constantinople landed a strong body of Russians, commanded by General Lazareff, whose arrival stopped the progress of Ithurbide. On the 4th of May peace was concluded at Konia, and Mahmoud 'Ali obtained the object of his armament, the invasion of Syria. Adana, he resigned the tributary vassal of the Porte. So much was Turkey weakened through this war, that Mahmoud, despairing of further independence, threw himself into the arms of Russia, and on the 8th of September, he trekked to the Russian stele, by which Russia bound herself to assist Turkey with an army whenever she should want it, in acknowledgegment of which Mahmoud promised that no armed ship of foreign nations should be allowed to take up quarters in the Porte. Erdogan of Russia Mahmoud was more fortunate in an expedition against Tripoli, which was brought back under the sultan's immediate authority, and at Tunis also he succeeded in obtaining obedience to his orders.

Mahmoud's hatred of Mahmoud 'Ali began now the principal motive of his actions. As early as 1834 things were so bad, that Mahmoud not only resolved upon a fresh war, but the himself at the head of his troops to conduct it in person. But in crossing the Bosporus he dropt the sacred sword of Soliman II., which fell into the sea and was lost for ever, and this act he committed, he says, because he had resolved to return to Constantinople. War was prevented by the mediation of England, France, and Russia, but the sultan nevertheless continued preparing for a contest which he wished, and which he feared, but the contest which he bestowed upon his military preparations was surprising. Yet the result did not answer his expectations. He thought that because he had a system of order on paper, the administration was well conducted, and that the execution of his orders was to be intrusted to persons who themselves had first to learn obedience and impartiality. In his first war with Mahmoud 'Ali he was the victim of the knavery and rapacity of some of his ministers, especially the old Khoorew Pasha, without ever suspecting how unfairly he had been dealt with. Sufficient money was intrusted to Khoorew to defray the expenses of the war, and the strictest order was given as to the expenditure. He failed, but Hussein Pasha, who commanded part of the army, received only a scanty supply of ammunition, most of the ammunition wagons which were sent to his camp being found empty at their arrival. Mahmoud also gave 4000 purses to Khoorew, directing him to send them to Hussein, who had received orders to pay for the provisions and horses, which he should be obliged to take from the peasants; the money, however, remained in the hands of Khoorew, and when, after the end of the campaign, Hussein returned to Constantinople, he did not dare to complain of the peculation of the powerful minister. Reshid Pasha, another commander, received the most solemn assurances that he would get for his army, which was sent to the Turkman Pasha, in the different towns of that part of Asis Minor where he was to command, but when he came to Ak-Shehr, his men found that the best chance of getting a dinner was in the Turkman Pasha.

The second war with Mahmoud 'Ali would perhaps not have broken out so soon (1840), but for the pasha's manifest design to subject all Arabia to his authority; and it is said that the sultan was urged by Russia, and especially by Great Britain, to open the campaign in that year, although he knew that his army was not yet able to take the field with any chance of success.

On the 25th of June, the Turkish army under Hafiz Pasha was entirely defeated by Ithurbide Pasha, near Nisibis; and there being no other army to oppose his victorious career, it was evident that Turkey was lost if the European powers did not interpose. Mahmoud was fortunately not desired to hear of the disgrace of his arms. He died on the 1st of July, 1840, a few days before the news of the battle of Nisibis threw the seraglio and the capital into consternation. It was after the passage of the Bosphorus by Dikablos, in 1828, that for the first time in his life Mahmud evinced symptoms of despair. From that time care and disappointment produced a visible effect upon him; after his defeats in the first Egyptian war he threw himself into a state of dejection and dispair, and declared of Mahmoud 'Ali impaired both his body and mind. At the beginning of 1840, his health was so bad as to indicate a speedy dissolution, and he increased his weakness by excess in food. His eating was of the most extravagant kind; he declared his aliment to be tuberculous phthisis; shortly before his death they were dismissed, and, as the younger Michael in the 'Biographie Universelle,' says, were superceded by an English quack, through whose efforts the sultan died two months before his death could have been expected to take place according to the nature of his disease. Mahmoud was succeeded by his eldest son, Abdul-Mejid, the present sultan.
he went great no limits to our nation's success and years by those of number, namely infinity.'

(Salton Malamud and Malamud's Ali Pasha, by the authority of France, Russia, and Turkey, 3rd edition, London, 1835; Von Hammer, Des Osmanischen Reiches Staaten-Verfassung und Staats-Pflege von bedenken in the text, and another accident which happened to two which he made for the latter king made Mariano to give up the art of inlaying in disgust. These two chests or caskets suffered so much in the transport from Florence to Hungary by undue care or the change of climate, that when they were uncovered by Benedetto before the king, a great part of the inlaid-work, owing to the effect of the moisture on the glue, fell to pieces, to the great dismay of the king and the horror of the artist, and had to be remade.

Benedetto felt that an art in which the works were subject to destruction was also a drudgery unworthy the attainment of superior abilities, and he thereupon applied himself exclusively to sculpture in marble and to architecture.

Benedetto's marble works however were also of an ornamental character, diverse in detail, and of great variety, in the taste of the Renaissance. He first made a group of figures for the tomb of Guarino della Scala, and then one of the most famous marble groups in the world, the Virtues, in the Medici Chapel. His figures and pulpits were of a most elaborately, character, being loaded with beautifully executed small figures, besides other decorations. One of his masterpieces is the magnificent marble Nativity which he designed for the cathedral of Florence and which he finished the Magdalen in Santa Trinita, which was left imperfect by D'estacore da Sacinaco. In architecture he did very little: he built the porch of the church of the Madonna delle Grazie near Arno; a chapel for himself on his own estate near Prato; and he is said to have designed the Palazzo Strozzi. He died rich in 1498, aged only fifty-four, and was buried in San Lorenzo at Florence. He left the reversion of his property to the brotherhood of the Bigallo.

GIOVANNI DI NARDO DA MAIANO, the uncle of Benedetto, was likewise a distinguished artist, and in similar works as Benedetto. He was inducted with several important charges in Florence, and in 1472 was elected to the office of Lord of his native city. He was a pupil of Brunelleschi, who was the architect of the cathedral of Florence in 1446. At Naples he built the palace of Poggio Reale, and at Naples and of Madrid, also the triumphal arch, and the relics of the Castello Nervos (now the Arsenal). At Rome he built of Travertine stone the loggia of one of the courts of the Vatican; and the church and palace of San Marco for Pope Paul II. in the same material; and a report was long in circulation that part of the Colosseum was pulled down for the stones, but more charitable persons have presumed that the pope used only such stones as had already fallen. Giuliano commenced also, in 1464, a new nave to the church of the Madonna at Loretto, which was completed by his nephew Benedetto. Giuliano was still living in Florence in 1471, a fact clearly ascertained by Brunelleschi. He was also said to have been a pupil of Filippo Brunelleschi in the reign of Alfonso I. (1435-1458), is erroneous; this statement is also evidently incorrect from the fable of Giuliano being employed by Paul II., who was pope from 1464 to 1471.

(Vasari, Vita de Pittori, etc., and the Notes to the German translation by Schorn; Cipriani, Storia della Scultura; Rumoro, Italianische Forschungen; Maiano, Mastiletto, et al., 1754-1758. [SETTLEMENT, P.C.] MAIATE, MAIATI, Lords of Rimini, an historical family of Italy during the middle ages. Like many other great feudatories of Italy, the Maiati are said to have been of Italian origin in the fourteenth century. One of their names is mentioned in some chronicles as 'Vicarius,' or Imperial Lieutenant of Rimini, under Osso III., A.D. 1002. It is not, however, until the second half of the thirteenth century that we find authentic records of this family as being at the head of the Guelf family in Rimini. Giovanni Maiati, called 'il Zoppo,' or 'the lame,' married Francesca, daughter of Guido di Polenta, Lord of Ravenna. Paolo, brother of Giovanni, seduced his wife, and being caught in adultery with her, they were both condemned to death. This tragic event forms the subject of one of the most beautiful episodes of Dante's Inferno. After many vicissitudes, owing to the factions of those times, we find Gualbert Maiata, in the early part of the fourteenth century, acknowledged by the Pope as Lord of Rimini, Pesaro, Fano, and other places in fief of the Papal See. His descendants continued in possession of Rimini, with various interruptions, till the time of the House of Hapsburg. His family was greatly deprived of his dominion by the Pope, and retired to Venice, after which several of the same family figured in the service of that republic. One Carlo Maiata had already distinguished himself in the wars of the fifteenth century, between the Duke of Milan and the Venetians. (Sanvoro, Famiglie Illustri d'Italia.)

MALAXIS, a genus of plants belonging to the natural order Orchidaceae, and to the tribe Malaxideae. It has a potent perianth, the lip posterior, erect, entire, similar to the pedale and smaller than the sepal; the spur absent; the stigma rhomboidal; the rootstock acaule, entire; the anthers terminal, continuous with the short column; and the apex of which it appears as if it were excavated with two imperfect cells; the pollen-masses connected at their apex; the germen upon a scale or disk.

Of this genus there is one British representative, M. palea. It is a small plant, with a stem from one to four inches in height. The leaves are remarkable for being fringed at the end with hair, such as hair. The germen are covered with spongy bogs, where it grows upon the moss, in the chambers of an epiphyte, and not amongst it other bog-plants.

MALINGERING. [FRIEDEN DISEASES, P.C.S.] MALLOW, MALVACEAE, C.; MALVA, P.C.S.; MAMMAL, JAMES HARRIS, FIRST EARL OF, was the only son of James Harris, the learned author of 'Hermes,' and other well known works. His mother was Lady Margaret Carteret, and he was born in the county of Somerset, Esq.; and he was born at Salisbury on the 21st of April, 1746, the day of the battle of Culloden. The Harrises had been settled on their estate of Orcheston St. George, in Wiltshire, since the middle of the sixteenth century. The father of the subject of the present notice was the first of them who was ever in parliament or employed in any political capacity; but they may be considered as having belonged to the first class of the gentry in their county. The father of the author of 'Hermes' married a daughter of the second Earl of Shaftesbury.

After having been put in the first instance to the grammar-school, he was sent to Winchester, where he remained till September, 1762. His father, who was by this time in office, now kept him with him in London for above six months, and then sent him to Merton College, Oxford. Since that time, in several years he expresses himself as unable to decide whether his father did right or wrong in introducing him to society before he was sent to the university. 'I believe,' he says, 'the seeing many of the leading men in administration, hearing them converse on public business, contrived to form my mind to think on public affairs, and to give me an interest in them which, probably, otherwise I might never have acquired; but the mixing at that age (seventeen), and raw from school, in all the gaiety and dissipation of London, filled my mind at the same time with false objects of admiration, false notions of excellence, and gave me, in my own conceit, a knowledge of the world so much greater than I supposed my fellow-collegians could possibly possess, that I apprehend I carried to the university a considerable share of self-sufficiency, and no great propensity to attend lectures and conform to college rules.' But although he professes to look back upon the years he passed at Merton as the most unprofitably spent of his life, he appears to have no means altogether neglected a study amidst the heat of living, the desire of the place. Even in his own disparaging account he admits that, although he never saw his tutor at any other time, he did receive his instruction for one fortnight, when he took it into his head to be taken as a student by the name.

On leaving Oxford in 1765 he was sent for a year to study at Leyden; and here at least he seems to have made excellent use of his time, spending many hours daily amongst his
books, while he also mixed much in society. He then, after being eight months at home, set out in 1767 on a short continental tour, in the course of which he visited Holland, Prussia, and in the autumn of the same year he was, through the patronage of Lord Shelburne, his father's colleague and friend, appointed secretary of embassy at Madrid, and thus entered public life at the age of one-and-twenty.

Three years after the affair of the Falkland Islands occurred, when he chanced to have been left at Madrid as charge d'affaires, and, acting upon his own responsibility, he had the good fortune to secure the recall of Sir John Sinclair, the Spanish government to concede the object in dispute. The Falkland Islands, the acknowledgment of our right to which was thus obtained from Spain, were given up by England four years after; but the temper and firmness, as well as talent, with which Harriet had managed his successful negotiation, gave so much satisfaction to his government, that he was the following year appointed to the post of minister at the court of Berlin. He retained this mission for four years, and then returning to England in 1776, married Harriet Mary, second daughter of Sir George Anyward Cornwall. In 1777 he was sent as ambassador to St. Petersburg, and, having in the mean time received the Order of the Bath in 1780, he remained in Russia till his health compelled him to return home in 1784. He had ever since 1770, notwithstanding his being abroad, held the two important posts of the English Church, and had, like most of Lord Shelburne's friends and connections, attached himself to the party of Mr. Fox. When Fox, however, was now superseded in the direction of affairs by Lord North, Sir John Sinclair and Sir James Harris the part of minister at the Hague, to which it had been intended that he should have been appointed if the Fox and North administration had remained in power; and he accepted it with the full approbation of Mr. Fox. While at the Hague he succeeded in negotiating, in April, 1788, the treaties of alliance with Holland and with Prussia, by which the power of the Stadtholder was at that time preserved from being overthrown by the democratic party, and Holland in all probability rescued from the grasp of France. For this great service, as it was considered, Sir James was, in September of the same year, raised to the peerage as Baron Malmsbury.

He now, after a short visit to Switzerland, returned to England. He continued to act with the Whig party in parliament till 1795, when he formed one of the large body of the friends of Mr. Fox who went over to ministers with Burke and the Duke of Portland. Lord Malmsbury was now sent over by Mr. Pitt on a mission to Berlin, where he prevailed upon the King of Prussia to enter into a second alliance with England and Holland, which however did not last for quite two years. But he succeeded in negotiating the marriage between the Prince of Wales and Caroline, the daughter of the Duke of Brunswick; and, after having gone through the ceremony of marrying her Royal Highness by proxy, he returned to England. His Diary relates many curious particulars respecting this affair, the issue of which was hardly more unhappy than he had anticipated that in all probability it would be; but his directions left him no option but to take his chance. It is stated, however, that he was never forgiven for the part he acted by the Prince, 'with whom until then he had been on terms of great intimacy and confidence.'

His last missions were those on which he was sent in 1796 and 1797 to Paris and Lille, to negotiate a peace with the French Republic, and which were attended with no result. He was then attacked by a fever, in which, in his own opinion, unhinged him for being again employed on any foreign service of importance. In 1800 he was createdEarl of Malmsbury and Viscount Fitzharris. He died at his house in Hill Street, London, Nov. 20, 1826, leaving a son, who succeeded him in the title, and three daughters.

Lord Malmsbury was without doubt one of the very ablest diplomats of his time, and a man of great general talent. Tall, dark, and handsome, his figure was graceful, and he was said to resemble his mother, Harriet, as St. Thomas More resembled his father, Henry. His manners were kind and gentle, his conversation mild but earnest and impressive, his deportment graceful and polished. It is said he was a Whig and a decided advocate of all salutary reforms, but strongly attached to the institutions of his country, and fearful of all imperfectly considered changes and innovations.

The following is a list of his works in the order in which they were published—

MALMUS, REV. THOMAS ROBERT, was born in 1768, at the Rookery, a small but beautiful estate in the county of Surrey, in the neighbourhood of Guildford and Woking. Charles, 1st Earl of Malmesbury, Daniel Malmsbury, the eldest son of Robert Malmsbury, who was his second son, was never sent to any public school except to the academy at Warrington, and that for a very short time. Besides the instruction which he received from his father, he was for some time under the private tuition of Robert Graves, author of the 'Spiritual Quixote,' whose house, however, he left when young, and was afterwards instructed by Gilbert Wakefield, with whom he remained till 1784, when he was admitted of Jesus College, Cambridge. He took the degree of B.A. in 1788, and that of M.A. in 1797, when he was made a Fellow of his college. Having then orders about the same time, he undertook the care of a small parish in Surrey, near his father's house, but he occasionally resided at Cambridge, in order to pursue his favourite course of study with more advantage.

In 1805 he married the daughter of Mr. Nares, a member for Christchurch, a pamphlet called 'The Crisis,' which however, at the request of his father, he did not publish. It was directed against the government of Mr. Pitt in general as well as against certain measures of the Lord President of the Council. He also published 'An Essay on the Principle of Population,' as affects the future Improvement of Society, with Remarks on the Speculations of Mr. Godwin, M. Condorcet, and other Writers.' The book excited considerable attention; but finding that his facts and illustrations were imperfect, in 1790 he went abroad in search of materials to establish his theory more completely. He settled for a month in the autumn of 1799 at Hamburg in company with three other members of his college, Dr. Edward Clarke, Mr. Cripps, and Mr. Otter. In Sweden the party separated, when Dr. Clarke and Mr. Cripps preceded to the north, and Mr. Malmsbury and Mr. Otter journeyed leisurely through Sweden, Norway, Finland, and part of Russia, and then returned to England. During the short peace of 1802 Mr. Malmsbury travelled through France and Switzerland with some of his relations, observing whatever was curious in nature or art, but especially examining into the state of the people, and collecting materials for the improvement of his work. In 1805, he published a new edition of his 'Essay on the Principle of Population,' with the omission of the controversial parts, but much enlarged in what relates to the doctrine of his father-in-law Mr. Eckersall, at Bath, where he died December 29, 1834. He left a widow and a son and daughter.

The attention of Mr. Malmsbury had from an early age been directed to political economy, in which he was much stimulated by his conversations with his father. The two most important of his works are, the 'Essay on the Principle of Population,' of which an analysis is given in the article POPULATION, P. C., and the 'Inquiry into the Nature and Progress of Rent,' the leading principles of which are stated in the article REALTIES, P. C.

When a boy, while at Cambridge, Malmsbury displayed a great love of fighting for fighting's sake, a keen perception of the ludicrous, much relish for wit and humour, and considerable comic power of imitation; but his character gradually changed: he became more serious, more sedate, but he became placid, temperate, patient, and forbearing under the obloquy which was heaped upon him. His manners were kind and gentle, his conversation mild but earnest and impressive, his deportment graceful and polished. When a Whig and a decided advocate of all salutary reforms, but strongly attached to the institutions of his country, and fearful of all imperfectly considered changes and innovations.
MALUS, ETIENNE LOUIS, a distinguished philosopher and military engineer, was born at Paris, June 23rd, 1775. He received his first lessons under the eyes of his father, Anne Louis Malus de Mity; and, in early youth, his time appears to have been nearly equally divided between classical and mathematical studies. This judicious combination of the two great branches of education had the happiest effect. By this means, he obtained a solid foundation of those developments of genius by which his name will descend to the remotest posterity. His memory was very retentive, and it is said that, even near the close of his life, he could recite from memory all the plays of Shakespeare of considerable length. His taste for classical literature is shown by the fact that, when seventeen years of age, he had written a tragedy entitled 'The Death of Cato'; but subsequently his studies were almost exclusively of a scientific character.

At the time that the tragedy is said to have been written, young Malus was, after a strict examination, in which he acquitted himself to the satisfaction of the persons in authority, admitted as a pupil in the Academie des Sciences, in the spirit of the times, being the intention of his father that he should enter into that branch of the public service; and he is said to have immediately distinguished himself by his diligence and his scientific talent. From some causes, however, which is not explained, but probably because his father, who held the post of Treasurer of France, had become suspected by the government (the great revolution having commenced), he was dismissed from the service. He then, as a means of subsistence, entered the army as a private soldier. He was for a short time employed in that capacity, with the battalion to which he was attached, in repairing the fortifications of Heliopolis, which had been destroyed by the advance of the Egyptian forces. Having then obtained a position in the government having decided upon the formation of the Ecole Polytechnique, inquiry was made for a certain number of young men who, having completed the usual course of education, were capable of being sent to the Ecole Polytechnique, and Malus, after being admitted to that institution, was immediately placed in the first class, and recommended to the celebrated Monge.

During three years he prosecuted his studies with extraordinary ardour, and distinguished himself by his applications of analysis to the solutions of some intricate propositions; he is said also to have occasionally communicated his mathematical subjects. It is added that he then commenced those researches concerning the properties of light, which prepared the way for his subsequent discoveries in optics; and his first step in this brilliant career was the investigation of the path of a ray of light after being reflected from or refracted into a medium having a surface of any form.

On quitting the Ecole Polytechnique, Malus was for a time employed as a professor of mathematics in the military school at Metz; but the small fortune which he possessed, his family having suffered great losses during the Revolution, and perhaps an inclination in favour of a more active life, induced him to abandon the project which he at one time entertained of devoting himself entirely to the sciences. He therefore entered a corps of engineers with the rank of captain; and, in 1797, he was sent to the Army of the Sambre and Meuse. He accompanied that army across the Rhine, and was present at the actions of Urkatz and Alten-kirk.

At the termination of the campaign Malus went to Paris, and, in the following year, he embarked with the expedition to Egypt under Bonaparte. He was engaged in the battle of the Pyramids, and in the attack of Alexandria; he was also employed as an engineer at the sieges of El Arish and Jaffa; and, after the taking of the latter place, he was appointed to superintend the repair of its fortifications. While performing this duty he fell ill of the plague, and lay for some time in the military hospital which he had assisted to form; he recovered, however, with little aid from medicine, and he was almost immediately sent to fortify Damietta. He was afterwards engaged in the action for which landed at Aboeiker; he was also at the battle of Heliopolis, at the affair of Cosa, and at the surrender of Cairo.

When the Institute was founded in that city, he was appointed one of its members; and in the first volume of the 'Décade Egyptienné' there is an account of an excursion which he made far into the country, with his discovery of a branch of the Nile which had not before been noticed. Malus continued in Egypt till the remise of the French army capitulated, when, in 1801, he returned to his native country in an English vessel. Exhusted by the arduous services in which he was engaged, and having been expatriated and nearly ruined, he yet performed the duties of an officer of engineers, having, in 1804, been appointed by the government to superintend the construction of the works which were being added to the fortifications of Paris, and then the title of sub-director of fortifications, and he was made a member of the Legion of Honour. Five years afterwards he was appointed superintendent of barracks in the department of the Seine; and in the following year, 1810, he was made a member of the Committee of Fortifications and Lieutenant-Colonel of Engineers.

Almost immediately on his return to France, Malus married a daughter of Koch, the Chancellor of the University of Giessen, to whom he became attached before his departure for Egypt; and, during the rest of his life, all the time he could spare from his professional avocations was spent in the cultivation of the sciences, particularly in the continuation of those optical investigations which he had commenced at the Ecole Polytechnique. His first published work was entitled 'Traité d'Optique,' in which he treated the phenomena of the reflection and refraction of light, and in which he particularly distinguished himself by his experiments and researches concerning the reflection of light in transparent media. It was known that when a pencil of light has entered into glass, or other transparent substance, the internal reflection takes place either before it arrives at the posterior surface, or at a certain distance from that surface on the exterior; but it had been found impossible to determine, though an incapable of the amount of this latter case, which case was manifest, to which of the cases either of the observed reflections should be referred. Malus overcame this
difficulty by applying successively to the surface an opaque medium, which, by preventing the refraction of the emergent rays, proved that the observed refraction had taken place within the glass, and a transparent medium which, by permitting the rays to pass through the glass, afforded a reflection from the external of the latter.

The subject of double refraction in crystals was very important. In 1810, the Institute of France offered a premium for the best answer to this question and Malus immediately entered with ardour into this field of research. It was while prosecuting his experiments that he observed an interesting phenomenon which only one of genius has the power of rendering available as steps to great discoveries. He then resided at Paris, and, happening one day to direct a prism of crystal which he held in the angle formed by the pencils of rays on which there was a brilliant light produced by the reflected rays of the setting sun, he was surprised to find that, while turning the crystal round, one of the images produced by the double refraction in it varied in intensity, and alternately appeared and disappeared. As such phenomena had not been observed when the prism was directed to any other bright object, as the flame of a candle, Malus was for a time at a loss to divine the cause; but after making several observations on the light from the same windows, he ascertained that the effect was produced only when it fell on them at a particular angle of incidence, which he determined from the known position of the sun with respect to the surface of the building.

In the prosecution of the researches to which this interesting discovery gave rise, Malus found that when a pencil of light from a point source passed obliquely through a crystal, the angle of incidence equal to 45° 35′, or from the surface of water at an angle of incidence equal to 52° 45′, the reflected light possessed the same properties as were exhibited by one of the pencils produced by the refraction in a crystal. He observed also that when the pencil reflected from a transparent medium, at a certain angle of incidence, is made to fall on another such medium at an equal incidence; if the plane of the second refraction is coincident with the plane of the first, the light is reflected as usual; but if the planes are at right angles to one another, no reflection takes place at the second surface, the pencil of light being wholly refracted.

To the effect produced on light so reflected, Malus gave the name of polarization; conceiving that the particles of light have poles or axes, and that, on entering the doubly refracting crystal, those which form one of the pencils may arrange themselves so as to be capable of being transmitted through it, while those which should have formed the other ray may have such dispositions as prevent the passage, in certain directions, from being effected.

It may be said to have laid the foundation of a new branch of physical optics; and an account of them is given in the Mémoires de la Société d'Arcueil, as well as in the Mémoires of the French Institute. Of this discovery he was immediately engaged; he published in 1811, though, on account of the war, there was scarcely any intercourse between Great Britain and France, the Royal Society of London awarded him the Rumford medal; thus performing a noble act of homage to scientific merit in the person of a foreigner, and one who carried arms among the enemies of the country.

In 1810 Malus published at Paris his Théorie de la Double Refraction de la Lumière dans les Substances cristallines; and in the following year he presented two papers to the Institute on some remarkable phenomena of polarized light. In the first of these he is shown that when a pencil, after having been obtained by reflection, falls on glass, part of it is reflected and part transmitted; the reflected part is wholly polarized in one direction, while the transmitted part consists of two portions, in one of which the particles preserve the character of direct light, and in the other the light is polarized in a direction contrary to that of the reflected pencil: it is added that the portion which has the character of direct light diminishes gradually by transmission through several pieces of glass, and it is observed also that as the whole of the transmitted ray becomes polarized in a direction contrary to that of the reflected pencil. In the second paper it is shown that all polished bodies, opaque and transparent, polarize light by the reflection and transmission of light on glass, and that the polished surface acts as a filter.

A particular disposition of the reflecting surface, he succeeded in exhibiting them: he discovered that the pencils reflected from polished metals are polarized in opposite directions, while those which are reflected from transparent bodies are polarized in one direction only. He had observed the modifications which parts of organized bodies, whether animal or vegetable, produce on light when they are thin enough to transmit the polarized pencil through them; and he noticed that the colures, which are sometimes seen in Iceland spar. He ascribed these images to the effects of flares parallel to the longer diagonal of the crystal rhomboid, but Sir David Brewster has since ascertained that they arise from those which act upon the transmitted light at both of their surfaces.

During the short remainder of his life, Malus continued his scientific researches amongst all the duties which his post as a member of the Committee of Fortifications required. He was chosen Examiner in Physics and Descriptive Geometrical Academie Polytechnique, and though his health was fast declining, he neglected no occasion of performing the functions of that office. He was on the point of being made Director of the Studies in that Institution when he was removed by death from the scene of his useful labours.

He died in Paris, February 28th, 1812. In the thirty-seventh year of his age; and his wife, who, ever since their union, had alleviated his labours by her attentions, and watched him in his last days with affectionate solicitude, survived him three years. Malus enjoyed the esteem of the public for the benevolence of his character.

(M. de l'Académie, Acad. des Sciences.)

MALVA, a genus of plants belonging to the natural order Malvacae. It has numerous styles, a double calyx, the outer one three-leaved, the inner one five-leaved. The flowers are regular and many-celled; the cells one-seeded and circularly arranged.

M. Moschata, the Musk Mallow, has an erect stem, kidney-shaped leaves, with five or seven deep pinnatifid lobes, the lower leaves being oblong-ovate, the fruit-stalks erect, and the fruit hairy. The flowers are large and rose-coloured, on axillary single-flowered peduncles, crowded at the extremity of the stem and branches. It is native in many parts of Europe, and is found in Britain in grassy borders of fields and by waysides.

M. sylvestris, Common Mallow, has an erect stem, and is distinguished by its kidney-shaped leaves with seven deep crenate lobes; the fruit hairy. The flowers are small and purple colour, much longer than the calyx, which is hairy. It grows on waste places and roadsides in Britain, and is native in most parts of Europe. The whole plant is peculiar, especially the round purple petals, which, when dry, are flat and thick, are employed in dyestuffs and in general for removing supposed acroni- mias, in making tinctures, as a medicine, and in various sizing and polishing. This species is the Malva of Pliny, lib. 20, cap. 21; also, in Columella, lib. 10, cap. 247: it is the Malva of Theophrastus, lib. 9, cap. 17, and the Malva of Dioscorides, lib. 2, cap. 144.

M. rotundifolia, Dwarf Mallow, has a decumbent stem, roundish heart-shaped leaves with five shallow acutely crenate lobes, the outer sepals linear lanceolate shorter than the ovate acuminate stellately hairy inner ones. The flowers are small and purple, and two or three times longer than the calyx. It is common in waste places in most parts of Europe, and is native of Britain. It is the M. euphrasia of Fries, the dyspepsia of Dioscorides, loc. cit., and the Malva sylvestris of Pliny, loc. cit.

M. borealis has its outer sepals linear, as long as the ovate acutelyglabrous but strongly ciliated inner ones, the petals as long as the calyx; the fruit pubescent, glabrate, renicate-surfus. It is the M. pusilla of Smith, the M. rotundifolia of Fries. It is found in Britain, near Hythe in Kent. There are many other species of Mallow.

Those are common in many parts of Britain, and the others are of little importance excepting as ornamental plants. Those best for cultivation for this purpose are M. Moschata, Morelia, alias, Moreuma, and purpurea. There are several species which are sometimes seen in Iceland spar, and cuttings of them will strike root freely if planted in light soil underneath a handglass. The greenhouse species may be propagated in the same manner. The hardy perennial kinds
should be plucked in the open border, and may be propagated either by seed or by dividing the roots. (Don. Gardenia's Dictionary; Babington, Manual of British Botany.)

MANDATE, as one of the contracts of the Roman law, was constituted where one by special agreement, or by tacit assent, had undertaken to perform some act gratuitously for another. The obligations incumbent on the mandatory, and duties of the mandatory, were so many that the Romans excused the consideration for what he had undertaken to do, but from his leading the mandant to believe that he would perform it, and thus causing damage if he should neglect it. It is distinguished as an early method of payment for personal service, forming the service undertaken without authority from the person for whose behoof it is undertaken; and from Locostio-Conductio, where the service is remunerated. The characteristics of this mandate, in a special sense, are stated in Heineccius, Ad Inst., tit. 27, and by Galus, iii. 155, &c. In England mandate in this simple sense is a department of the law of Bailment. (Bailment, P. C.) In Scotland there is a wide departure from the old Roman meaning of the word, and almost every instance where one person acts for another is said to be under the contract of mandate; thus the commercial agent buying and selling, or the solicitor conducting a litigation, are said to be 'Mandatories.' The case in which, by the practice of the law of Scotland, the word mandate in its old sense is best exemplified, is in trusts, which, instead of being subject to the control of the agent, in the manner in which they are treated in England, are merely treated as simple mandates. The acceptor of a bill is held to be a mandatory of the drawer. (Mandragora, [AEtops, P. C.]

Manganese, according to Arsenio, exists only in mineral form. During the prevalence of pneumonia medicine, preparations of manganese, particularly the bixoxide, on account of the large quantity of oxygen it can yield, were much employed; but since the views of Beddoes and others, who recommended them, have become obsolete, the articles suggested to be used have fallen into oblivion. A rational ground for reviving some of them is to be found in the facts that oxide of manganese exists as a constituent of the bones, and in some cases be deficient in these structures, and also that carbonate of manganese exists in some of the mineral springs of Carlsbad and Marienbad, and hydrochloric of manganese exists in the waters of Kreuzentnach. The presence of these salts in waters much celebrated for their utility in various chronic diseases has suggested their employment in some of the complaints which are frequently benefited by them. But even if their curative properties are insufficient to establish them as valuable medicines, the deleterious effects of some forms of manganese justify a notice of them in this place. The extensive employment of black oxide of manganese in the preparation of black card, as an artifice of the shoemaker, has of late years been followed by the use of an aqueous solution of paralytic which should be early noticed, insomuch as after it is thoroughly established it seems altogether incurable; and the only chance of escape is the complete abandoning of the occupation. It is supposed that the paralytic started by extremities, affecting the motor nerves only, for the sensibility is unalloyed. A staggering gait is the first symptom of its commencement. This is often perceived sooner by others than by the sufferer. No chole, nor constipation, such as attends the use of lead, is manifested. (See Dr. Cooper's paper in 'British Annales of Medicine.' i. p. 41.)

Bixoxide of manganese has been used internally in pills, and also as a gargoyle; externally as an ointment in some obstinate cutaneous affections. It does not appear entitled to much attention. Hydrochlorate, and still more sulphate of manganese, deserve attention as chologogue, emulsivum, and promotor of perspiration. The disagreeable taste and the power of disabling of soda or other alkali, and its carbonate, are incompatible with it, as decomposition occurs. Its power of augmenting the secretion of bile renders it a valuable agent along with mercury, or a substitute for it when mercury for some reason be not borne. It is useful in gout.

MANGLE. (Calceking, P. C. S.)

MANSOTANA. [Leyacbt, P. C. S.] MANNING, ROBERT, is more usually called Robert de Brunne. He owes this name to his having been a Gillermine canon in the monastery of Brunne or Brown in Lincolnshire. He lived in the reigns of Edward I. and his successor, and was the writer of one of the earliest of the Metrical Chronicles whose language can be called English. His work however is merely a translation from the French. It is in two parts: the first, translated from the 'Brut d'Angleterre' and 'Roman de Roi' of Wace and Galmar, begins with Æneas and ends with Cadwallader; the second, from Cadwallader to Edward I., is translated from the Chronicle of Peter of Auvergne, the first part of which was published by Hearne in 1725. The measure of it is octosyllabic in the first part, and Alexandrine in the second. Its poetical merit is very small; but it is interesting as an early manuscript of French language, and valuable for its information, both historical and literary. Robert made in English rhymes a translation, which has 'ever been printed, of Saint Bonaventura's treatise 'De Cena et Passione Domini.' He translated also, freely, into octosyllabic verse, 'Manuel Focha,' or 'Manual of Sins,' which used to be attributed to Bishop Grosheath on insufficient grounds. Of this unprinted translation specimen are given in Warton's work and elsewhere. Hearne has supposed, with little reason, that Robert de Brunne was the author of the old English metrical romance called 'Ryeberde Cuer-de-Lyoon.'

MANTUA, the common name of a family of artists of Mantua, of the sixteenth century. The progenitors appears to have been Ghis, but few particulars regarding the lives of its members are known.

GIORGIO GRIM, called Giorgio Mantuno, was born in Mantua about 1520. He was painter, sculptor, engraver, and architect, and author of a commentary on Vitruvius—'Gli occuri e difficili Passi dell' Opera di Vitruvio.' ft., Mantua, 1558. He was born in Mantua, to which city he returned the works of the sixteenth century; they are well drawn and executed with great mastery, much in the style of Mantuanism. Among the most valuable are the Last Judgment, and the Prophets and Sibyls, by Michelangelo, in the Sistine Chapel; and the Dispute on the sacrament and the School of Athens, after the frescoes by Raphael in the Vatican.

Bartsch describes 129 prints by ADAMO GRIM, called also Mantuno; and 46 by DIAZ GRIH, called also DIAZ GRIM. The years of the former are dated from 1568 to 1576, and those of Diana from 1578 to 1588. Diana was the daughter of Giovanni Battista Mantuno, and was married to Francesco de Bellotto, and settled in a fine house in a fine spot near Mantua, where she was the subject of several etchings,

Diana, Notizie Istoriche degli Intaglatori; Bartsch, Feinr-Graver; Brulliot, Dictionnaire des Monogrammes, &c.,

MANUEL, NICOLAS, sometimes called Deutsch, a celebrated Swiss painter, was born at Bern, in 1484. He is the Emmanuel Tedesco who studied under Titian at Venice about 1511, and he became very celebrated for a series of pictures (probably in disembrett) of the Dance of Death, Todesmitten, painted between 1514 and 1522, in the cloister of the Dominican convent at Bern. The picture consisted of forty-six subjects, forty-one of which were the actual Todesmitten; it has been long since destroyed, but the compositions are preserved in prints and copies: the wall on which it was painted was pulled down in 1800. Manuel was an active reformer, and many of his designs are reflections upon the scene of the Reform, which he considered as the work of God. This is the result of his great political; from 1523 he took an active part in an official capacity in the government of Bern. He died in 1580. His own portrait, and several drawings are in the library of Bern. There are a few copies of his oil color, at Basel and at Bern.

Of Nicolas Manuel, until recently, little was known beyond what has been told us by his pupil, Johann Herbst. He appears to have been a man of universal ability; he was painter, sculptor, wood-engraver, poet, soldier, and statesman; and he was lately made the subject of an elaborate work by Dr. Grineen, which is to be published at the University of Leiden, and will be a valuable contribution to the study of Malers, Dichters, Kriegers, Staatsmanns, and Reformators, Stuttgart und Tübingen, 1821.

(Magner, Neues Allgemeines Künstler-Lexikon.)

MANTUA, [Mivius, P. C. G. C., C. S. B.]

MARCELLUS, ULPNIUS, a Roman jurist, who lived under Antoninus Pius and his successor. He was employed by Pius as one of his legal advisers (Capitulina, Anton., 152), and his influence was considerable. He was succeeded by Aurelius, the successor of Pius (Dig. 28, tit. 4, 3), for Marcellus speaks of the proceedings in a case before Aurelius, a.d. 166, in which the emperor delivered judgment. Marcellus (Dig. 26, tit. 2, s. 13), as quoted by Ulpianus, cites an oratio of the Divi Fortunus, proving that he survived Aurelius, if the word Divi was used, and is not introduced by Ulpianus. It is conjectured that this is the third of the Marcelli who are cited in Book X of the Commentaries of Commodus, the successor of Aurelius, and by his military success excited the jealousy of the emperor. (Dion Cassius, liv. 8.) But it is doubtful if this Ulpianus Marcellus is the jurist. (See the note of Reinaud on Dion Cassius.)

The writings of Marcellus mentioned in the Florentine Index are thirty-one books of Digests, six books on the Leges Juliae et Papiae, and two books of Responsa. There are 169 excerpts from Marcellus in the Digest; and other works of his are cited besides those just enumerated. Marcellus is quoted by Marcellinus, Ulpianus, and Paula frequently, and by other jurists.

MARCH, a market and post town in the chapselsy of March in the parish of Doddington, in the northern division of Wiltshire hundred in the Isle of Ely, Cambridgeshire, 9 miles to the east by north, and 7 miles by the Eastern Counties Railway to Ely, and from thence 20 miles by coach-road through Chatteris to March. The area of Doddington parish is 38,240 statute acres, that of the chapelry of March 20,440 acres; the population of the parish in 1841 was 8,945, of whom 5,006 were in the chapelry of March. The population of the chapelry at the former enumeration was, in 1801, 1811, 1821, 1831, 1841, 5,117. The number of houses in the chapelry in 1831 was 1,016, inhabited by 1,029 families; 42 uninhabited and 16 buildings; in 1841 it was 1,163 inhabited, 32 uninhabited, and 12 building. In these returns the town is not distinguished from the rural districts of the chapelry.

The town consists principally of two streets, in the form of the letter T; the street which forms the stem of the letter runs north and south, and is lined with houses on both sides; the cross street runs in an irregular line on the north bank of the old river Nene, having scarcely any houses except on the north side of the street, the south side being for the most part closely skirted by the river, which is crossed by a bridge at a little distance from the town: the church, or rather chapel, stands at the southern extremity of the town: it is dedicated according to some statements to St. Mary, according to others to St. Wundreda, and is said to have been erected in the æra of the Christian纪元. The church is a small and commodious town-hall, where meetings are held. The town is within the jurisdiction of a Court of Requests established at Ely for the recovery of debts due under 10s. There is a weekly market on Friday for butcher's meat, and there are two yearly fairs. Some trade in agricultural produce is carried on by means of the river Nene, which is navigable.

The chapelry of March is united with the vicarage of Doddington; the clear yearly value of the united benefices is 732s., with a glebe-house; they are in the rural deanery, archdeaconry, and diocese of Ely. There were in the chapelry in 1833 nine day-schools, with 522 children of both sexes, giving not one in nine of the population (according to the census of 1841) under daily instruction. Two of the schools, with 304 children, were national schools supported by various endowments, and attended by the children on Sunday also; and there were two other Sunday-schools supported by Dissenters, with 170 children.

Margravine Charlotte, Countess of St. Anselm (Government Gazette; Parliamentary Papers; Lyons' Magna Britannia.)

MARCIANUS AELIUS, a Roman jurist, who was writing after Marcellus Severus, for he calls him Divi (Dig. 50, tit. 4, s. 7). He was the son of the successor of Severus, for he names him Divus (Cod. 9, tit. 8, s. 8). He probably wrote chiefly under the reigns of Septimius and his son Caracalla. The works of Marcius, which are mentioned in the Floriculite Index are sixteen books of Institutiones, four books entitled Regularia, two books on Appellations, two books on Publica Judicia, a single book of Deletories, a single book on the Hypodecatoria (formula) and a single book Ad Sinum Institutiones. Marcius is cited by Ulpianus and Paula (Cod. 7, tit. 7).

There are 275 excerpts from Marcius in the Digest. (MARCH, p. 251.) MARGRIOTONE D'AREZZO, a celebrated old Italian painter, sculptor, and architect, was born at Arezzo, about 1215, or perhaps a little later, but he was probably at least twenty years older than Cimabue, who was born in 1240.

Margrion was a painter of the Government school, and of great reputation in his day. He executed many works in Arezzo, both in tempera and in fresco; in the latter style he painted the whole interior of the church of San Gianito. He was the author of a treatise on the history of his native city, of which the survivor is a work entitled "The History of Arezzo," in nine books. The frontispiece of the work is very ornamental, and it is said to have been the occasion of the destruction by the duke Cosmo de' Medici in 1517, to make room for improvement in the fortifications of Arezzo. Most of Margrion's works have now perished; but one, which according to the same writer, was his masterpiece, namely, San Francesco, painted for a convent in Sargiano, still exists, and is engraved in Lasati's "Eturia Antiqua," i. 7. Vasari speaks highly of a picture on canvas, illustrating the lives of the Virgin and John the Baptist, in small figures, and in which, says Vasari, Margrion much surpassed his larger works; but this picture has also perished.

There is still an old painted wooden crucifix by Margrion in the church of Santa Croce at Florence, where it is placed by the side of a similar work by Cimabue. Margrion's fame was very great in his time, but it was almost wholly eclipsed by the reputation of Cimabue and Giotto. He had a peculiar way of stretching and painting his canvases; they were primed with plaster mixed with size or glue made of strips of parchment, and were stretched and fastened with the same glue that was used for priming. In sculpture, as in painting, Margrion was more successful than in painting. There is still but a few, in the cathedral of Arezzo, a receding marble statue of Gregory X. over the tomb of that pope, which was also constructed by Mar- grion; and a powerful and richly colored painting, but this has been defaced by time: this monument, according to Vasari, is Margrion's masterpiece. As an architect, Margrion conducted the building of the cathedral of Arezzo, some time after the death of a very
Lafo, but according to the design of that architect, from about 1277 until 1289, when a war broke out between Aragon and Florence. He died at Aragon shortly after 1289, aged seventy-seven, and was buried in the old cathedral of that place, where his portrait was painted by Spinello Aretino, and the following epitaph was inscribed upon his tomb:

The less the better picture Marquess's,  
Cur requisit Dominicus terminalis altus plus.

(Vasari, Vite de' Pitori, &c., and the Notes to the German translation by Schorn)

MARINERS' CONTRACT. [SHIPS, P. C.]

MARIUS TYRILLUS. [PLEOEMANS, CLAUDIUS, P. C., p. 104.]

ARMON, SHAVERLEY, the son of a Northamptonshire squire, was born in that county, became a gentleman commoner of Oxford in 1617, and proceeded master of arts in 1624. He squandered a good fortune; took military service in the Low Countries; and in 1633 became one of the officers in the troop raised by Sir John Suckling for the king in his expedition against the Scots. But, becoming sick at York, he returned to London, and died there before the end of the year. Besides small scattered poems, he wrote three plays: 1: 'Holland's Leaguer, an excellent comedy,' 1632, 2v. 2: 'A Fine Companion,' a comedy, 1632, 4to.; 3: 'The Antiquary,' a comedy, 1641, 4to., a drama of considerable merit, which is reprinted in the tenth volume of Daveney's Collection.

MARQUIS'S RULERS. Among the methods which have been devised for facilitating the operation of drawing parallel lines, there is that by which consist in making one ruler slide along the edge of another in almost every case the most expeditious and accurate.

A triangular ruler having two of its edges at right angles to one another, having its side with one of its edges perpendicular to the length of a common rectangular ruler constitutes, apparently, one of the first contrivances of this nature. It is said to have been originally employed in Germany, from whom its use extended to other parts of Europe.

A triangular ruler of the form just mentioned is called by the French artists an équerre.

The most approved construction and application of a triangular ruler are due to an artist named Marquis, who resided in London, and by his name only the instrument is now known.

Where many lines are to be drawn parallel and perpendicular to one another, as in making plans or elevations of buildings, or the horizontal projections of the ramparts of fortresses, such an instrument is particularly useful. The right-angled triangle, as well as the rectangular rulers which accompany it, is made of box-wood, ivory, or some metal; and the scale on the sides of such rulers are certain scales with graduations in equal parts.

The ratio of the hypotenuse to the shorter side of the triangular ruler is usually as three to one; and on one of the surfaces of it, which is used to draw on the scale, the triangles which are drawn are short line which serves as an index. The rectangular rulers which are used with the triangle are each about 12 inches long; they have scales on both surfaces, and the graduations are cut close to the edges in order that the coincidence of the index on the triangle with any required division may be accurately made.

Parallel to each scale there is generally cut another, each of its divisions having the same proportion to each division on the corresponding scale at the edge as the shortest side of the triangle has to the hypotenuse (1 to 3 usually). This second scale is used entirely as a plotting scale for the purpose of laying on paper lines of given lengths in feet, yards, or other measure, or of measuring them when traced; the former scale being intended wholly for the peculiar purpose of the sliding triangle.

The plotting, or, as they are called, the natural scales, are of various kinds, but usually from 20 parts to 60 parts in an inch; the others, which are called artificial scales, vary consequently from divisions equal to \( \frac{1}{4} \) to such as are \( \frac{1}{8} \) or \( \frac{1}{16} \) of an inch.

When it is required to draw lines parallel to others at any given distance on a scale representing feet (for example), the apparatus is used in the following manner. Let \( MP \) be a rectangular ruler on the edge \( MN \) of which is the scale to be used: if, for example, the drawing is to be made on a scale of 30 feet to an inch, the scale is that whose divisions are each equal to \( \frac{1}{30} \) of an inch; then, the edge \( AC \) of the triangle being made to coincide with a given line, the index \( a \) must first, in a movement of the ruler \( MN \), be placed in coincidence with the zero of the scale (in the middle of the length of the ruler), the triangle must then be moved along \( MN \) till the index \( a \) is (suppose at \( a' \)) in contact with the number on the scale which expresses the number of feet in the perpendicular distance between the given line and that which is to be drawn.

If the triangle is in the position of \( M'C' \), the position of \( A'C' \), along its edge \( A'C' \) will be the line required; for it will be parallel to \( A \) at a distance from it equal to the given number on the natural scale. The reason is manifest; for imagine \( A'D \) to be drawn parallel to \( BC \), then the triangle \( A'D \) is similar to \( ABC \); consequently, since \( A'E \) is equal to the distance \( a' \) between the two positions of the index, \( A'D \) will be the same part of \( A' \) or \( a' \) as \( BC \) is of \( A'D \).

That is, by the construction of the triangle, \( A \), the intersect between the parallel lines is one-third of the distance \( a \) on the scale, or equal to the corresponding distance on the natural scale.

Lines may be drawn parallel to one another by means of the side \( BC \) of the triangle; and it is evident that the distance between them \( (BC) \) for example will bear the same ratio to one another as the line \( AB \) or \( a' \), born to \( A \); that is, \( \frac{1}{3} \) to \( 3 \). But the edge \( BC \) is principally used in drawing lines perpendicular to given lines; if, for example, the edge \( BC \) were in coincidence with a given line, and it were required to draw, through a given point \( G \), a line perpendicular to such line, the triangle must be moved along \( MN \) till \( AC \) passes through the given point; then the line \( A'C' \) will be perpendicular to that line.

When lines are to be drawn parallel to one another at considerable distances, the edge \( BC \) is made to coincide with an edge \( MN \) of the rectangular ruler; and both ruler and triangle being moved together till \( AC \), then perpendicular to \( MN \), coincides with the given line, the triangle is moved along \( MN \) till the same edge \( AC \) is at the required distance from the original line; when the line may be drawn.

Marquis's rulers have occasionally been formed and used in a different manner. Instead of a single scale on the ruler \( MN \) has been made to serve the purpose by means of several triangles in which the lengths of the sides have different ratios to one another. Thus, if a scale of divisions be required to coincide with a line at an edge of \( MP \), and if a right-angled triangle in which the hypotenuse is twice the length of one of the sides be used with it; on sliding the index of the triangle over each division, the edge \( BC \) is moved to the distance \( \frac{1}{2} \) of an inch: if the hypotenuse be four times the length of the shortest side, lines drawn contiguously to the longer side will, on sliding the index over one division of the scale, be equal to \( \frac{1}{2} \) of an inch; and so on.

MAROCO. [ARIOLES, P. C. S., p. 83.]

MARSH-MALLOW. [ALTHREA, P. C.]

MARSHALL, JOHN, Chief Justice of the United States of North America, was born in Fauquier County, Virginia, September 24, 1756. He was the son of Colonel Thomas Marshall, and the eldest of fifteen children. He received a little instruction at home, but was taught at an early age the rudiments of a regular course of education, and was never at any college. On the breaking out of the American war, he engaged with enthusiasm in the cause of his country. In 1776 he was appointed a first lieutenant, and in 1777 was promoted to the rank of captain. He was present at the battles of Brandywine, Germantown, and Monmouth. There was however a redundancy of officers in the Virginia army, and Marshall having applied himself to the study of law, was admitted to the bar in 1780, and in 1781 resigned his commission in the army.

Thenceforward he devoted himself to the law, and rose rapidly to great distinction in the profession.

Marshall was a member of the Virginia convention for the ratification of the constitution of the United States, and both then as well as subsequently in the Virginia legislature distinguished himself by his judgment and eloquence. He was twice offered the situation of attorney-general, and declined.
both occasions declined on private grounds to accept the offer. In June, 1797, John Marshall, Charles Cotesworth Pinckney, and Edward Rutledge, jointly and which were sent to France as envoys extraordinary and ministers plenipotentiary. Marshall returned to America in 1798. In 1799 he became a member of Congress, and on the 8th of May, 1800, he was appointed Chief Justice by the President. In the same year he succeeded John Jay as chief justice of the United States, and from that time till his death continued to fill the office with increasing reputation for ability and integrity. He died July 6, 1835, at the age of eighty. He had resided for some time in Richmond, Virginia, in hope that by medical advice and change of scene his declining health might be improved. Three of his children were with him, but his eldest daughter, who was then residing at Baltimore, on his journey to attend his father's death-bed.

Jude Marshall was the author of the 'Life of Washington,' originally published in London in 4 vols. 4to, the first volume in 1804, the fifth in 1807. The work was criticized by the 'Edinburgh Review' (October, 1808) severely, but perhaps not unfairly, as having been swelled out to an unreasonable bulk by historical matter unconnected with the life of Washington; as containing no details of his private character and habits, which Judge Marshall had ample opportunities of knowing; as diffuse and undiscriminating in narrative, and heavy and unadapted in style. This criticism seems not to have influenced Marshall, for his 'Marshall in the West' was published in 1832, comprised two volumes, and greatly improved. The 'History of the American Colonies,' which in fact occupied the first volume of the original work, he had published in 1802.

As a judge, it is admitted that he was one of the most distinguished that America has produced. Judge Story, who was twenty-four years his senior, in a letter on the bench of the Supreme Court, wrote in 1828 an article in the 'North American Review,' vol. xvii., 'On the Public Services of Judge Marshall,' in which he says:—Splendid as has been the judicial career of this eminent man, it is perfectly impossible that the inestimable value of his intellect, or the unrivalled accuracy of his learning, should be duly estimated except by the profession of which he was so great an ornament.

Many of those exquisite judgments which have cost days and nights of the most elaborate study, and for power of thought, beauty of illustration, variety of learning, and elegant demonstration, are justly numbered among the highest reaches of the human mind, find no admiration beyond the ranks of lawyers, and live only in the dusty repositories of their oracles.

We emphatically say of Chief Justice Marshall that his master-mind has presided in our deliberations, and given to the result a cogency of reasoning, a depth of penetration, a grace of expression, and a power of imagination that have surprised all who have studied the cases in his opinion, and have been struck with the unexampled degree of analysis and comprehensiveness of conclusion, to which none others offer a parallel.'

MARSCHALL, JOSHUA, D.D. [SNERAMIRE MISION, P.C. S.]

MARTINO, [MEMMI D. MARTINO, SIMONE, P.C. S.]

MARY, [SINT, is the easternmost of the Azores or Western Islands, and lies near 37° N. lat. and 25° W. long. It is about seven miles in length from east to west, and five miles in breadth from north to south, and contains an area of about 36 square miles, or 27,000 acres. The island consists of a plain and an elevated district. The plain occupies about one-third part on the west side of the island, the other part being formed of an elevated ridge running from north-west to south-east, which rises to a double peak (Pico Alto) 1889 feet above the sea, and of which the sides decline on the north, east, and south to muriel cliffs, about 200 feet in height, with which the sea meets. The ridge is slightly undulating, and like the higher tract cut by ravines, terminating in cliffs more than 100 feet high. The aspect of St. Mary is therefore on all sides bold, and the coast abrupt or precipitous, and surrounded by the usual accumulations of fallen masses.

The surface on the west side is much overlaid with stones, and bears a sparse vegetation of grasses and weeds. The most elevated parts of the ground is covered with common grass and some shrubs, on the east side, or only the site, any land which is fit for cultivation. The cultivation is limited to wheat, Indian corn, potatoes, and beans and peas. There are few plantations of trees, but those of oranges have been lately increased. Aloes and the prickly-pear cactus grow wild, and the Rocella tinctoria to a large size. Nothing is known respecting the climate of the island, except that there is much less rain than in that of St. Michael's.

The population, according to the census of 1840, was composed of 4686 individuals, of whom about one-half belonged to the small town of Villa do Porto and two hamlets; the remainder were dispersed in different parts of the island. There were then 2913 males and 2473 females. There are some public schools, established by government, but in 1840 they were only attended by fifty-two pupils, all males. The

The whole quantity of agricultural produce is comprised in 2500 quarters of wheat, 2450 quarters of barley, 200 boxes of honey, 100 boxes of sugar, a small quantity of white beans, peas, and other articles. About one-half of the wheat and all the oranges are exported to St. Michael's. This produce is derived from one-sixth of the landings, and to a smaller extent from the remainder.

St. Mary in Azores was discovered in 1481 by Goncalo Velho Cabral, a Portuguese, who was sent by the Prince Don Henrico to explore the part of the sea in the Azores are situated, and the island received from him the name of San Miguel, as he discovered it in 15th of August, the festival of the Assumption of the Virgin Mary. Soon afterwards it was settled by Don Goncalo.

(Munt. Description of the Island of St. Mary, in London Geog. Journal, vol. xiv.; Bird, Description of the Azores or Western Islands.)

MARY, DUCHESS OF WÜRTTEMBERG, or the Princess Marie d'Orleans, was born in April, 1815, during the exile of her father Louis-Philippe, then Duke of Orleans, and residing at Palermo with his wife Amelia, second daughter of King Ferdinand of Naples. The Princess Marie spent much of her childhood at Twickenham, near London; her youth was passed under the care of her mother at Nevers, until her father was raised in 1830 to the dignity of King of the French. From her childhood a devoted love for art had been a distinctive feature of her character, and as soon as she was at an age to benefit by it, the infant Marie-Philipphe commandd some of the most skilful artists in their several styles to attend upon her. Ayi Scheffer was her master in design and painting, Pierre Jean David instructed her in modeling, and the famous sculptor Bertin taught her drawing in water-colours. She was married to the Duke of Württemberg in 1837, and she died at Pisa, in January, 1839, in consequence of injuries suffered from the congestive failure of her lungs at Stuttgart.

She is said to have left numerous designs, and to have executed many beautiful drawings. Some of her works in sculpture have already acquired her a European reputation; among these her marble statue of Joan of Arc is the most popular. Joan is standing with her eyes fixed upon the ground in deep meditation, her arms are crossed upon her breast, and in her right hand she grasps her sword; her costume is that of a noble and a knight combined. The original statue, now at Versailles, is of the size of life, but it has been copied in many materials and in many sizes. She executed also an equestrian statue of Joan of Arc at the moment after she had slain an Englishman with her battle-axe; there is also a small model by her of the Death of the Chevalier Bayard. And in a chapel at Fontainebleau there are some windows painted after her designs. Many contemporary journals, French and foreign, celebrated the character and ability, and deplored the untimely fate of this accomplished princess.

MARYGOLD. [CAZEROLLA, P.C. S.]

MASCARA. [ALDERS, P. C. P. 330]

MASCIA CALANDRA. [FLORENZO], mathematician, was born at Bergamo in 1750. His studies were at first directed to the languages and literature of Greece and Rome, and to these subjects he applied himself with unwarried diligence. After ten years he was solicited by the government of humanity in the university of his native city, and he attracted some notice at that time by a poetical dissertation on what he called the false eloquence of the pulpit. He afterwards became professor of Greek in the university of Pavia; and,
MA S

269

MAS

having taken orders in the church, he acquired the title of Abbe.

He was not till he was twenty-seven years of age that he began the study of mathematics; but he rapidly acquired a taste for the sciences, which induced him to abandon his classical pursuits, and so great was his progress in this branch of study, that he was assigned professor of geometry in the college Mariano at Bergamo.

When the Revolution took place in the north of Italy, on the invasion of the country by the French, Mascheroni was chosen a member of the legislative body in the Cispinese Republic; and soon afterwards he was sent to Paris to assist in the formation of the new system of weights and measures.

He was at one time also engaged at Bologna, with other mathematicians, in the performance of experiments with a view of proving the rotation of the earth on its axis by the place at which a body struck the ground when let fall from the upper part of a lofty building.

Mascheroni published in 4to. a work entitled "Sulle Curve che servono a delineare le Ore Ineguali Antichi nelle superficie Plane," Bergamo, 1784; and in the following year, at the same place, a tract, also in Italian, on the Equilibrium of Volumes, 4to. In this tract the higher branches of analysis are employed, and the investigations are extended to subjects beyond those which are treated in the works of the earlier writers on the applications of science to practical engineering. In the year 1788 he published "Geometria del Compasso," in which are ingenious solutions of several geometrical propositions by means of a pair of compasses only; that is, by the intersection of circular arcs, without the employment of straight lines.

He also published a "Trattato della Inversione," in which he has confided his method of the inversion of the branch of a curve in which it is required to find between or beyond two given points, and in the direction of a straight line joining them, other points whose distances from the former are in any assigned proportions; these are given in the work methods of finding points in lines perpendicular or parallel to, or making given angles with, a line joining two points whose positions are assigned; of determining a mean proportional between, and this, or one of those points, from the other, and of inscribing polygons in circles. There are also approximative solutions of problems, such as the duplication or multiplication of a cube, and the trisection of an angle, which require, in the usual method of operating, applications of the cosine sections or other curves.

Besides the mathematical works just mentioned, and a tract containing notes on Euler's "Institutiones Calculi Differentialis," Mascheroni published some verses which were addressed to the Countess Giannoni, an elegy on the death of Borda, and a poem entitled "Invito di Daino a Lechia," in which he introduced a precise description of the objects contained in the museums of Paris; and philosophy at the same time.

He died in July, 1809; in consequence, it is said, of too close application to his scientific studies, leaving several manuscripts, and among them one on "Pyramidometry," a subject which he much esteemed. He had previously investigated, but which Mascheroni had not noticed, a branch of the subject on the application of geometrical curves to the calculation of the volume of bodies, and the surfaces which envelop them.

(Biographie Universelle; Montucla. Hist. des Mathematiques.)

MasSENA, ANDRE, Prince de Eslng, Duke of Rivoli, and Marshal of France, was born at Nice, 6th May, 1758. 'Several of the French marshals," says D'Irakilly, 'and the most famous—Massena, for example—was Hebrew; his real name was Massenais ("Connoisez," l. 200). Left an orphan at an early age, his education was greatly neglected. He appears to have spent some years of his youth at sea with a relation who was captain of a trading vessel, but having taken a dislike to a sea-faring life, he abandoned it, and in 1777 he was appointed to the army as a private soldier in the regiment Royal Italian, in which one of his uncles was a captain. After a diligent discharge of his duties in that regiment for fourteen years, he obtained the rank of sergeant, which, when he afterwards became a colonel, he described as the step in his military career which had cost him the most to gain. Dis- couraged by this slow promotion, he retired to his native city, where he made an advantageous marriage. Events connected with the French Revolution, he deposits at this period, and he was appointed by the sufferings of his fellow-soldiers to the rank of adjutant-major of the battalion raised in the department of the Var, of which regiment he subse- quently became colonel. He was made a member of the general of brigade, and general of division a few months after.

In the Italian campaigns of 1794 and 1795 he served under the generals Kollermann and Scherér, and it was chiefly owing to his skill as a tactician that the victory was gained in the battle of Saorgio (August, 1794), and on the Col de San Giovanni in 1796. Indeed the greatest part of the success that has generally been attributed to the ability of the plans which the influence of whose military conceptions he so justly appreciated, that he summed up the "favourite child of victory." The scenes of his principal exploits were Montemonti (8-11 April, 1798), Millesimo (14 April, Castiglione (39 June—3 July), Arcola (15-17 Nov.), and Rivoli (9 January, 1797). At the peace of Campo Formio, October 17, 1797, Massena was sent to France to present to theDirectory the following three proposition of the handful of Austria. In February, 1798, he was appointed to the command of the army which, under General Berthier, was occupying Rome and the Papal States. His appointment to this office was equally disliked both by the French soldiers and the inhabitants of the said country, for they both became the victims of that insatiable avarice which on every occasion characterized this general. The multiplied complaints which his disposition gave rise to at last obliged him to resign his command and to return to Paris. He there published a "Memoire" in justification of his conduct, notwithstanding which he was left without employment till 1799, when the important duties of the head of the Bureau of War were assigned to him. In the direction of this campaign he evinced a military talent of the highest order. The memorable battle of Zurich (5th and 6th of June, 1799), in which he obtained his triumph over the Russians and Poles, saved France from the invasion of the allied powers, and led to the dissolution of the coalition which had been formed between the Russians and Austrians.

On the return of Joseph from Egypt, Massena was employed by him to defend Genoa, which was at that time invested by a large Austrian army, and closely blockaded by the English fleet under Lord Keith. He arrived there on the 18th of February, 1800, and defended it against the superior forces, and amidst the horrors of famine, till the 3rd of June, when, unable to prevent the rising of the inhabitants, he was compelled to agree to an honourable capitulation. Only eleven days after this capitulation, Bonaparte, conqueror at Marengo, stipulated the evacuation of this city, which was again re-entered by the French under General Suchet, on the 24th of June, 1800. (Genoa, P. C.)

Massena's name does not appear connected with any event of importance till May, 1804, when, on the same day that Napoleon became emperor, Massena was created a marshal of France. In 1805 he was again appointed to the command of the army in Italy, where he was only tied to the line of the Po by the Archduke Charles: he conducted this campaign with varying success, but he was at last enabled to drive back the Austrians into Germany, and to effect a junction with the grand army of Bonaparte (June 1805). After the peace of Preising (20th Dec., 1805), Massena had the honour of being one of those who was to conduct Joseph Bonaparte (Bonaparte, Joseph, P. C. S.) to Naples, which kingdom had been bestowed upon him by his brother (from whence he returned after having established by force of arms the authority of the new king). By his success over the insurgent Calabrians and the reduction of the fortress of Gaeta (18th July, 1806), he enabled Joseph to take possession of his new kingdom. In 1807 he was appointed to the command of the right wing of the army opposed to the Russians in Poland, and his services during this important campaign were rewarded by the title of Duke of Rivoli, in commemoration of the skill and bravery which he had displayed in a most brilliant campaign, against the grand army of the Emperor (1807). P. C. S.: a large sum of money was at the same time given him to support his new dignity.

A singular and untoward circumstance occurred on his return to Paris. A party who had espoused his person in so many battles without receiving a wound, had the misfortune to lose the sight of his left eye while on a hunting-party, a portion of shot having accidentally struck it.

The Austrian campaign of 1809 was not attended with considerable lustre on the already high military character of Massena. He greatly distinguished himself at Landshut and Eckmühl. The rapid capture by storm of the strong castle of Eierendorf, which, from its position, was considered as impregnable, especially attracted the admiration of Napoleon. At the battle of Asling (Lannes, P. C. S.) the defence of the village of Aspern was confided to Massena, and it is gene-
Finally believed that to his obdurate resistance in that village the French army was indebted for its preservation. His eminent services on that most critical occasion were rewarded by the rank and title of Prince of Essling.

The same success attended the operations of Massena at Parnawa. At the destruction of Wagram he was obliged to direct the movements of the left wing of the army while seated in a carriage, on account of an injury produced by a fall from horseback. An incident there occurred which showed that in more than one respect he was "the favored child of fortune;" at one time success appeared doubtful, and to animate his soldiers he was enabled to place on horseback; he had scarcely been so when a cannon-ball struck the very post on which the carriage had not been secured, and he had occurred.

In 1810 Marshal Massena was appointed to the chief command of the army in Portugal, which was about seventy-two thousand strong: his commission was to drive the British, under Wellington, from Portugal. His exploits in this campaign, though in many instances marked by great military talent, have not added to his reputation as a general, while the frequent examples of his cruelty, avarice, and breach of faith, recorded in the histories of that period, have left a deep stain upon his memory. One achievement, however—his masterly retreat into Spain after the failure of his attempts on the lines of Torres Vedras—has been the subject of the highest admiration, as far as even a military defeat can be considered, by both English and French historians. (Sir W. Scott, Life of Napoleon, vol. vii. p. 156.)

Massena was recalled from Spain in 1812, and the command of which he left was bestowed upon Marshal Marmont. His health having severely failed, he was unable to join the expedition to Russia. In the latter end of 1813 he was sent to Toulon to take the command of the eighth military division, from which place he formally declined his adhesion to the Bourbons, on the 6th of April, 1814, and was by them confirmed in his command. On the return of Napoleon from Elba, after some hesitation, he recognized his government, but kept aloof from all active participation in the events which took place during the Hundred Days. After Napoleon's second abdication he was appointed commander-in-chief of the national guard of Paris. Being chosen a member of the Council of War which was assembled for the trial of Marshal Ney, he at first declined sitting as a judge on a fellow-soldier with whom he had been for some time at variance, and when this objection was overruled he joined the majority of members in pronouncing for the incompetency of the court. (Ney, P. C. S.) Some months after these events he was denounced in the Chamber of Deputies on the charge of having been at the head of a conspiracy for the return of Napoleon, and having procured, and been satisfied with, the order afterwards publicly recelled the accusations which had been brought against him, in a "Memoire Justificatif," to which a reply was published in a pamphlet entitled "A Letter of a Citizen to Marshal Massena," which was written by a man in a spirit of such bitter invective that it produced a sensible effect on his mind and health, already enfeebled by bodily infirmities, and is said to have hastened his death, which took place, at Paris, the 11th of April, 1817. His will, which was pronounced by General Thiibault, was inserted in the "Mercure," and afterwards published separately.

Massena was gifted by nature with a powerful frame of body and with indomitable resolution. His bravery was rather characterised by perseverance than by impetuosity. He was considered the most skilful tactician among Napoleon's generals, and on the field of battle he was remarkable for the coolness and precision of his orders and for his penetrating insight into the intended movements of the enemy. He had moreover the invaluable quality in a commander of not being dispirited by defeat. His faults and vices we have already alluded to; they were principally rapacity and avarice, and they frequently brought down upon him the displeasure and punishment of his chief. (Allson, vol. iii. 4; Las Cases, Memoires de St. Hilaire; Court and Camp of Napoleon; Hist. des Batailles et Biographie Moderne; Palet, Memoires sur la Campagne de 1809, Paris, 1823-24, 4 vols. (This accurate military writer was aide-de-camp to Massena); Napier, Hist. of the Peninsular War.)

MASSON, ANTOINE. This celebrated French engraver and painter was born at Louy, near Orleans, in 1636, and was originally an armurier and damasquinier, damask-worker, and goldsmith, and an artist in much request in the days of armour and chivalry. Masson, who in engraving appears to have been self-taught, had extreme facility and certainty of execution, and he was one of the first artists who made a marked distinction in the textures of the objects which he engraved; he was also extremely successful in his mode of representing colour. The fantastic character of his plate was seen at the time of his death, and his engraved portraits, has been condemned by some critics as mere bravura to display his own remarkable facility in handling the graver; in some heads the features are engraved in continuous and peculiar lines. He was very fond of playing his skill also in executing hair, whether of man or beast, though he frequently sacrificed truth to his propensity for making those fine lines, and in draperies and animals he has given evidence that this peculiarity is not the most striking feature of some of his works. A print, after Titian, of the Disciples at Emmaus, is from the nature of the cloth generally known as La Nappe, and there is a dog in the picture which is such a mass of hair, that upon a close inspection it appears, says Wattelet, to be made entirely of straw; yet notwithstanding these peculiarities, says the same intelligent critic, this print is the best engraving after Titian. Wattelet says that Masson's faults are faults which he would have, and that they are always compensated by his beauties. The print of the Disciples at Emmaus has an additional value beyond its merits as an engraving for, with the exception of a few lines, it was done at the prayer of the praying disciple is the Pope Adrian IV, the other is the Emperor Charles V., the host is the emperor's confessor, and the attendant is Philip II. of Spain. Masson died at Paris, in 1699, and was a member of the French Academy of Painting. He has executed many portraits, several after his own paintings, and some of them are nearly of the size of life. Masson's portraits have a peculiar interest also as representing a group of the most distinguished men during the reign of Louis XIV. His historical pieces are not numerous, but they are all excellent. (Wattelet and Leroquc, Dictionnaire des Bonnes Arts; Robert Dumenil, Peintre-Graveur ; Nagler, Neues Allgemeines Künstler- Lexicon.)
Mahomedanism, Christianity, those of Zoroaster and Confucius, and the idolatry of barbarous nations. His geographical knowledge was no less extensive and correct than his acquaintance with history, and no Arabic writer can boast like him of learning at once profound and almost unlimited. In the introduction to Dr. Spranger's treatise of the 'Golden Meadows,' Mas'udi is thus compared with Herodotus. 'If it is the warmth for his own nationality and tenets without prejudice against what is foreign; the elasticity of mind, and the freedom from opinions, without want of firmness and principles; the thirst for correctness of information without preconceived erudition, the admiration for the works of men, who were entitled to succeed Mohammed as Khalif; 7 'Kitab al-means,' the 'Book of Questions on the Causes of Religious Opinion.'

Asiatic, or the full import of the terms, which are used by the different Mohammedan sects; and while he informs the reader of the mysteries of the extreme North, he will all at once forget his subject and transfer him into the desert of the Sahara. In this respect the Arab has a singular advantage over the Persian, and delight of the learned in the East, was too voluminous to meet with popularity. According to Burchardt there is a MS. of it in the library of the mosque of St. Sophia, which, incomplete as it is, consists of twenty large volumes in 4to., and ten at least are said to be wanted to make it complete. The 'Akhbâr ez-ze'mân' was a general history of all nations; it has never been printed; MSS. are very rare in the East, and there are none in Europe. In the royal library in Paris however there is a MS. fragment of it on Egypt, of which there is a MS. translation by Pêris de la Croix, which has been preserved by later orientalists. The Arab Hezârâmân, by Dr. Tübingen, the 'Ibarat al-Akkâmâr,' the 'Ibarat al-Ma'tâm,' or the Book of Pearls gathered from the History of the Times,' of which there is a MS. copy in the Royal Library at Copenhagen, and another in that of Paris, is an extract from a work of the same name, preserved by the orientalist Rasmussen. Saint Simon however doubts this. This extract was made in the 9th century of our era, by Shehab-ed-din Ahmad-an-Mokri, a native of Fes in Morocco. 2 'Kitab al-advis,' 'The Book of the Middle,' the word 'advis' the plural of 'waiz,' being probably taken in the sense of 'proprietor,' not exceeding a certain size. This is the complement to No. 1, and treats of the most curious and important questions in history and geography. There is no MS. of it in Europe, and we know some of its details only through the quotations of other Arabic writers. Aware that his works were too voluminous, Mas'udi wrote, 3 'Moruj-al-dheeb我们会 al-mudalib,' which he celebrated as Meadows of Gold and Mines of Gems. This is an extract with additions from No. 1 and 2. In the Leyden MS. preserved by Dr. Spranger, the work is divided into 132 chapters, of which the doctor gives the titles in the introduction to the first volume of his translation of the work; in a Paris MS. it is divided into 129 chapters, 65 of which treat on foreign countries, and the remainder on the Empire of the Arabs. Mas'udi wrote nothing but the history of his time, whatever may be the date of the work, according to the author, for each chapter bears the date when the author finished it. This seems, however, scarcely credible. In A.H. 345 the author issued a second edition consisting of 7 volumes, but all were destroyed, and the work was again commenced, and met with less favour from the public than the first edition, of which there are many MSS. in the East as well as in Europe; but there is no MS. extant of the second edition. A Spanish Arab, El-Shaffi, a native of Nata, made an extract from the 'Golden Meadows,' and so did Reiske during his residence at Leyden. The 'Historia Hoc in 'Compendiosa Antiquitates Historiarum,' is a translation of a chapter of the 'Golden Meadows;' and it appears that the Arabic treatment of which Renaudot published a translation under the title 'Ancienne Relations des Indes et de la Chine de deux Voyageurs Mohammedans' is likewise a fragment of the work. It is probably of the second edition. Dr. Gildemeister published a translation of a chapter of it on India, entitled 'De Indis, in the 'Journal et Monumenta Asiae,' 1850, 8vo. He attempted to publish a translation of the whole work, of which the first volume, containing the first seven chapters, translated by Dr. Aloys Spranger, with the co-operation of the late Earl of Munster, appeared under the title 'El-Mas'udi's Historical Encyclopedia entitled Meadows of Gold and Mines of Gems.' 1st vol., London, 1841, 8vo. The 'Golden Meadows' treat on the history, geography, religion, manners, and polities of most of the Eastern and European nations, and are full of matter both important and curious.

The following are works of Mas'udi, some of which are extant in MS., but most of them are only known by being quoted by other writers:

1. 'Kitab fonun-al-m'drîf,' etc., 'Different Branches of Science, and of what has happened in bygone times; 5 'Kitab dekhâr-al-'ulûm,' etc., 'Treasury of Science,' etc.; 6 'Kitab al-fawziâr,' etc., a series of 10 books, embracing the highest importance to all Mohammedans, namely on those who were entitled to succeed Mohammed as Khalif; 7 'Kitab al-means,' the 'Book of Questions on the Causes of Religious Opinion.'

On Extravagant Opinions.' It is much to be regretted that there is no critical edition of this work; 12 'Kitab al-wâlî-nanîs,' 'The Physician of the Soul,' with a metaphysical digression on dreams; 13 'Hadîth al-dehâr,' 'Buds of Flowers,' contains historical information on the descendants of Mohammed and their virtues; 14 'Al-mas'udi we al-tarnîk,' 'On Principles and Compositions,' treats among other subjects of the influence of the sun and the moon; 15 'Kitab al-sirius as-sirîyân min al-sirîs al-molukîh,' 'The Book on the Seventy Chapters,' treats on the policy of kings, and is a very remarkable work.

We close this list with, 16 'An Account of the Establishment of the Fatemite Dynasty in Africa, from a MS. called to Mas'udi,' with notes, by John Nicholson, of the British Museum, at Saxe Cobourg, and Silvestre de Sacy, this work is a fragment either of No. 1 or No. 2 in our list. The MS. used by Dr. Nicholson is one of those which the unfortunate Dr. Secten purchased at Damascus, from the Mahomedan emir, of the reigning house of Saxe-Coburg, at Gotha; it was written in A.H. 627, and is consequently of more modern date. An orientalist well acquainted with the works of Mas'udi would confer a great benefit on geographers by writing a commentary on the geographical system of the author. Mas'udi had thoroughly studied the systems of Ptolemy and Marinus of Tyre, and he distinguishes between the maps of Ptolemy and those of the Syrian geographer. There is consequently no doubt that the geography of Marinus was extant in the 10th century of our era. Mas'udi speaks of the Arabic origin of the kings of Tibet, a fact which is likewise mentioned in the Chinese annals; of a Syrian empire anterior to that of Nineveh; of Wm in Armenia as the city of Semiramis; of cuneiform inscriptions, and other matters. And since the Arabic poem of which the Rev. Charles Forster has availed himself for deciphering the Hymylite inscription in the Holy Quran, Ghorsh and others, was taken from Schultens 'History of the Christians' mentioned above, it seems that there is no small chance of finding a clue to the Hymylite characters in the works of Mas'udi.'
MAT,CII, in Gunner'y, is a material employed in firing military mines or in discharging pieces of ordnance. Before the invention of the inro-lock, hand-guns or small arms were fired by matches, which the soldiers carried with them on service; and in such-lock fire-arms still used in war are the primitive Dunne's, 3, cap. 135; and of Plutarch (Sulla, cap. 13). Other plants, as species of Parietaria, Chrysosplenium, &c., were called 'wasp-wood' or the Green Manure, (hibiscus, Manual of British Botany; Fras, Synopsis Flora Plant. Classic.)

MAURICE, THE REV. THOMAS, was born about 1755, and, even his father, was then the Rector of the Christ's Hospital School. After his father's death the family was impoverished by an unfortunate marriage of the widow: and his education proceeded irregularly till Dr. Parr, on opening his school at St. Aunck, prevailed on to receive him as a pupil, and treated him with great generosity and kindness. At the age of nineteen he was entered at St. John's College, Oxford, whence he removed next year to Jesus College. After taking his B.A., he was ordained by Bishop Lowth; and he held for some time the curacy of the large parish of Woodford in Essex, which in 1785 he resigned for a chapel at Epping, in order to obtain greater leisure for study. Next year his health gave way, but his life lived for more than four years. He had already written a translation of the 'Edipus Tyrannus,' and several other volumes of poems; and he long continued to publish volumes of verses. He was afterwards made Professor of Mathematics at University College by his distinguished tutor Lord Stowell; and before removing to Epping he had begun to concentrate his attention on the history of India, for dealing with which purpose the proposals in 1777 were addressed to the East India Directors. The religious spirit of the French revolution, alarming Mr. Maurice's mind, induced him to remodel his first work after it was nearly completed, and to add a considerable number of notes to it. These investigations on the Hindu mythology. His 'Indian Antiquities' began to be published in 1791, when two volumes appeared, in octavo: the rest were brought out at intervals, the completion of the work being mainly owing to the liberality of the Earl of Harborough, and the seventeenth and the eighteenth, in 1797. Meantime he had undertaken his 'History of Hindostan,' the three volumes of which, in quarto, were published in 1785, 1786, 1798; and a second edition appeared in 1821. In 1798 Earl Spencer presented him to the vicarage of Wormleighton in Warwickshire: next year he was appointed assistant librarian in the British Museum: in 1800 Bishop Tomline obtained for him the pension that had been held by the poet Cowper: and in 1804 he received from the Lord Chancellor the vicarage of Cudham in Kent. His 'Modern History of Hindostan,' in two volumes, appeared in 1802 and 1803. In 1804 he published several other volumes of verses, and was one of the last undertakings was his 'Memoirs: comprehending the History of the Progress of Indian Literature, and Anecdotes of Literary Characters in Britain, during a period of thirty years.' Of this work he completed the first two volumes in 1820, and 1822. Mr. Maurice died at his apartments in the British Museum, on the 30th of March, 1834.

MAURICIUS, JUNIUS, a Roman jurist, who appears to have been writing in the time of the emperor Antoninus Pius, from an expression which he uses (Dig. 33, tit. 2, s. 23); he was therefore a contemporary of Gaius. The only work of his that is mentioned in the Florentine Index is six books Ad Leges. There are four excerpts from Mauricius in the Digest.

MAURY, JEAN SIGFREID, Cardinal, was born on the 24th of June, 1640, at Avranches, in Normandy, to poor but respectable parents. He showed at a very early age a great disposition for learning, and, being destined by his parents for the ecclesiastical profession, he was placed at the seminary of St. Carde, at Avranches, to pursue his theological studies. At the age of eighteen he proceeded to Paris, in the expectation of earning a subsistence by the cultivation of his talents. Though he was without friends in that city, his first publications gave considerable notice. Encouraged by this early success he took orders, and devoted himself to the study of jurisprudence. In 1772 an 'Eloge' on Fénelon, which he published, was favourably received by the French Academy. The death of Charles Colin, the celebrated planter of Louisiana. He however soon returned to Paris, where he became very popular as a preacher. A panegyric of St. Louis, which he delivered before the French Academy, and of St. Augustine.
before an assembly of the clergy, met with so much success that the abbey of Freneade in the diocese of Saintes was bestowed upon him by the king, Louis XVI., who likewise appointed him preacher to the court. In 1786 he became a member of the celebrated Jacobin Club of Périgueux, and soon took a prominent part in the debates. From the first he extolled himself on the aristocratic side, where his eloquent oratory and peculiar talent at reply rendered him a formidable antagonist to Mme. Campan, the sculptor, who opposed admission which he advocated. In an oration, though it expressed opinions hostile to the great majority of the assembly, was often listened to with admiration and greeted with applause. His great moral courage and firm adherence to the principles for which he had advocated secured for him the respect and esteem of the more enlightened portion of his enemies. 'Opposed in debate by Mirabeau, Barnave, and Clermont-Tonnerre; interrupted at every step by the hisses or cries of one or two thousand spectators in the galleries certain of being defeated in all his efforts by an overwhelming majority; in danger of being stoned, turned up to the lamp-post, or torn to pieces at the close of every interesting debate, by the furious mob which often surrounded the Assembly, he never deviated from his duty, but was over to be found at a post. A true soldier of the church, he threw himself with undaunted valor into the breach, and it was hard to say which his greatest enemy was. Whether it was his declamation, the cutting force of his sarcasm, or the inexhaustible resources of his knowledge, were most contemptible.' (Allison, History of Europe, vol. i. p. 389.) On the 27th of November, 1789, the National Assembly was summoned, probably, by which every ecclesiastic in the kingdom was required to attend an oath to maintain with all his power the new constitution; and, in case of any priest's refusal, it was declared that he should be held to be a rebel and deprived of his benefice. To this constitution the pope had refused his sanction, on account of its hostility to the interests of the church, and the oath was indignantly refused by the great majority of the clergy. With the assurance of the pope and of the clergy of the Assembly, an infuriated mob surrounded the hall, threatening death to all who should refuse. On this occasion also Maury displayed his usual intrepidity, and boldly advocated the independence of his order. 'Strike, but hear me,' was his exclamation, when the last efforts of his impetuous eloquence in that Assembly were interrupted by the incessant cries of his political antagonists. At the close of the stormy session of the National Assembly, Maury, who could lend no further aid to the prostrate cause of royalty and religion, quitted his native country, and, at the invitation of Sir George Barrow, he sailed for England, where he was received with the highest distinction, and the loss of his benefits in France was more than compensated by his pecuniary elevation to the highest situations in the Roman church. In 1792 he was appointed by the Revolutionists, and afterwards appointed apostolical nuncio to the diet held at Frankfort for the election of the emperor of France II. This mission accomplished, in 1794 he was elevated to the dignity of a cardinal, and was instituted to the united sees of Monza, Fiesco, and Astino.

On the invasion of Italy by the French in 1798, though every effort was made to seize Cardinal Maury, he escaped under disguise to Venice, where he assisted at the convention assembled for the election of Pius VII. In 1799 he returned to Rome upon the conquest of Italy by Suwarow, and was accredited as ambassador to his exiled king, Louis XVIII., who recognized the characters of the Bishop of Fontainebleau. This office he resigned on the reconciliation of the church of Rome with the government of France under Napoleon, on which occasion he addressed to the First Consul a letter, couched in such terms of the highest respect as to give permission to return to France. This letter, which was deemed not to be in union with the tenor of his former conduct, subjected him in after-times to the reproaches and persecutions of the fanatics, who so often surrounded the ambassadour. Napoleon gladly received the proposal of a reconciliation with so distinguished a member of the church whose establishment he was restoring in France: an interview took place between the two sovereigns, and in May 1801 the pope returned to Paris. The flattering reception he there met with was calculated to attach the interest of this chief, who admitted him to his intimacy, and availed himself of his counsels in ecclesiastical matters. He received the pension assigned to the dignity of a French cardinal, and was appointed First Almoner of Jérôme Bonaparte. In 1807 he was elected a member of the Institute in the place of Target, one of the advocates of the cause of Napoleon. Archbishop of Paris, the unfortunate Louis XVIII. addressed to him the congratulations of Pius VII., between whom and Napoleon there had arisen much disagreement. Cardinal Maury was a warm and sincere admirer of the emperor, and he not only exposed his cause in the disputes with the head of the church, but took every occasion, which the frequent victories of this chief afforded him, of testifying his gratitude by the expressions of his sentiments. (His memoirs give a very full account of his diocese. These mandates, written in a style of the most florid eloquence, do not remind us of the impressive and energetic orator of the National Assembly; they were severely criticized by the adherents of the Jacobin regime, and by the witty frequenters of the Parisian saloons, who styled them 'archiepiscopal dispatches,' in allusion to their military tone, and their imitation of the style and manner of Napoleon's bulletins.

After the capitulation of Paris on the 80th of March, 1814, Maury was deprived by the Bourbons of the administration of his diocese; and in their resentment for his adherence to Napoleon's fortune they forgot his former daring and powerful support of their tottering throne. He then retired to Rome, where he was imprisoned during one year by the orders of the pope; he was afterwards allowed to live in semi-retirement; but his situation gave him no compensation for his resignation of the seclusion of Monte-Fiascone. In this retirement, deeply affected by the ingratitude of his former party and that of the pontiff, to whose elevation he had been instrumental, he died in 1816, aged 69 years, universally lamented as a man of talent rather than a man of sense, and a curate of the time of the League rather than an abbé of the reign of Louis XIV.

'Notwithstanding his extraordinary eloquence,' says the Duchess of Abrantes, who knew him intimately, 'the Abbé Maury had been before the Revolution, what he was in prostration, what he continued under the empire, a man of talent rather than a man of sense, and a curate of the time of the League rather than an abbé of the reign of Louis XIV.' She adds that his figure was in the highest degree contemptible, but that his diction she gives of it appears rather a caricature than a portrait.

His principal work, 'Essais sur l'Eloquence de la Chaire,' 3 vols. 8vo., published after his death by his nephew Louis Siffrein Maury, still maintains its well-earned popularity. His mind was formed to appreciate the eloquence of Masallion, Bossuet, and Bourdaloue, and his criticisms on the other French divines are in general as correct as they are temperate. In his review, however, of English pulpit oratory he manifests a want of acquaintance with the writings of our most celebrated preachers, such as Jeremy Taylor, Sheslock, and John Gill; and it is evident that his method of criticism is founded on the comparison which he draws between him and Masallion is necessarily most unfavourable to the former. His own Panegyrics of St. Augustine is esteemed one of the finest of his productions; and in the exercise of this art conjunctly with the Abbé de Bismont, to be the author of a work entitled 'Lettres sur l'Etat actuel de la Religion et du Clergé de France.'

There is a notice of the life of Cardinal Maury in 'L'Ami de la Religion et du Roi,' vol. xii.

(Biographie Nouvelle des Contemporains, vol. xii.; Allison, Hist. of Europe, vol. i.; Mémoires de la Duchesse d'Abrantes; Biographie Universelle Classique, Duclasse Paris, 1829; Biographie Moderne, vol. ii.; and a curious work entitled Dictionnaire des Girouettes, Paris, 1815, in which are fully detailed the political variations of the most remarkable characters in the empire, though sometimes with more sarcasm than truth.)

**MAX**

**MAX**
connected with the moving power and resistance are tangents to the circumferences are those at which the forces are conceived to be applied. Also, if several forces act at once as moving powers, and resistances to be overcome at once at various points, the resultant of all the forces of the and that of all the resistances must be taken for the effective moving power, and the effective resistance. The points of application of these resultant forces are to be found, and at these points such resultant forces are conceived to be applied; the effects of friction, the rigidity of ropes, and every other impediment to the action of the machine, are also to be estimated and applied as additions to the resistance which is to be overcome; and thus a complex machine is reduced to an equivalent mechanical power of a simple form. The velocities of the points at which these resultant forces are conceived to be applied are equal to the velocities of the power and resistance.

The motion in machines may be of two kinds. On the application of force to a machine previously at rest a certain movement is induced, and this movement for a time is accelerative; but in some machines, after a while, the resisting power and the friction of the materials destroy the acceleration, when, unless the machine is subject to variations of force, as is the case with those which are impelled by the wind or by the force of men or animals, the movement will become uniform. On the other hand, there are machines which are acted on by a constantly accelerating power, as when a weight at one end of a rope passing over a wheel descends from an elevated place and raises a weight attached to the other extremity.

If the velocities of the points of application of the equivalent forces are uniform, a simple equation will express the dynamical equation of the machine; for, $F'$ representing the moving power, and $V$ the velocity with which it moves, $f$ the force of resistance and $v$ its velocity, we have in the case of equilibrium

$$ FV = fv; $$

the first member of the equation is frequently designated the momentum of impulse, and the second the effect produced by the machine.

But the effect of a moving power on a machine in motion is different from that of an equal power on a machine at rest; for the effect produced by any constant power in the former case depends upon its relative velocity, or the difference between its own velocity and that of the machine, and, by Dynamics, it varies with the square of the relative velocity. Therefore, in order to introduce the absolute effect of a force into the equation of equilibrium in place of the efficient force, there must be given the velocity which would render the force quite ineffectual, as well as the initial velocity of the point of application: let the former be represented by $V'$, and the latter by $V$; then $F'$ representing the absolute force when the velocity is zero, and $F$ the actual force which the velocity $V$ being determined by the weight or resistance which is just sufficient to prevent the power from communicating motion to the machine, and $V$ by the velocity with which the machine can move when the resistance is zero),

$$ F' = F : V : (V' - V); $$

when $F = \frac{F'}{V} \cdot \frac{(V' - V)}{V}.$

Then the first member of the above equation $FV = fv$ becomes

$$ F' \cdot V - V'; $$

or, putting $v'$ for $V' - V$, which gives $V' = V + v'$, it becomes

$$ F' \left( \frac{v'}{V} \right)^2 = (V - v'). $$

Now, in order to find the velocity which is consistent with the production of the greatest effect by the machine, this expression, which represents the equivalent of $F'$, the efficient action of the machine, is to be a maximum; therefore, differentiating that expression, $v'$ being the variable, and making the result zero, we have

$$ 2V - 3v' = 0; $$

and, by substitution, $V = \frac{1}{3} V'$.
